SMOOTH NORMS IN DENSE SUBSPACES OF BANACH SPACES

SHELDON DANTAS, PETR HÁJEK, AND TOMMASO RUSSO

Abstract. In the first part of our paper, we show that \( \ell_\infty \) has a dense linear subspace which admits an equivalent real analytic norm. As a corollary, every separable Banach space, as well as \( \ell_1(c) \), also has a dense linear subspace which admits an analytic renorming. By contrast, no dense subspace of \( c_0(\omega_1) \) admits an analytic norm. In the second part, we prove (solving in particular an open problem of Guirao, Montesinos, and Zizler in \cite{Guirao-Montesinos-Zizler}) that every Banach space with a long unconditional Schauder basis contains a dense subspace that admits a \( C^\infty \)-smooth norm. Finally, we prove that there is a dense subspace \( Y \) of \( \ell_\infty(\omega_1) \) such that every renorming of \( Y \) contains an isometric copy of \( c_{00}(\omega_1) \).

1. Introduction

It is well-known that the existence of an equivalent smooth norm has profound structural consequences for a Banach space \( X \). For example, if \( X \) has a \( C^1 \)-smooth renorming (or just a bump function) then it is an Asplund space, so the dual of every separable subspace of \( X \) is also separable \cite{Asplund}. If \( X \) has a \( C^2 \)-smooth renorming then \( X \) either contains a copy of \( c_0 \) or it is superreflexive \cite{Enflo}. Finally, if \( X \) has a \( C^\infty \)-smooth renorming then it contains a copy of \( c_0 \) or \( \ell_p \), where \( p \) is an even integer \cite{Cascales}. The proofs of these results, as well as many other results concerning the best smoothness of concrete Banach spaces, depend at some point on the completeness of the spaces in question. Nevertheless, it is quite surprising that for separable spaces the completeness condition is in some sense also necessary. More precisely, Vanderwerff \cite{Vanderwerff} proved that every normed space with a countable algebraic basis admits a \( C^1 \)-smooth renorming. This result was pushed further to get a \( C^\infty \)-smooth renorming \cite{Cascales}. A slight reformulation of these results can be stated in the following form. Given any separable Banach space \( X \), there exists a dense linear subspace of \( X \) admitting an equivalent \( C^\infty \)-smooth norm. This leads naturally to the following, at a first glance rather bold, general question.

Given a (non-separable) Banach space \( X \), is there a dense linear subspace admitting a \( C^k \)-smooth norm, where \( k \in \mathbb{N} \cup \{\infty, \omega\} \)?
In the special case of $X = \ell_1(\Gamma)$ and $k = 1$, this problem was posed in the recent monograph by A. Guirao, V. Montesinos, and V. Zizler (see [8, Problem 149]), which was the starting point of our research. We obtain some partial positive results to this general problem, which remains open for $k = \infty$ (in the case $k = \omega$, we give a counterexample). In the first part, we improve Vanderwerff’s results as follows. Let $\mathfrak{c}$ be the cardinality of continuum.

**Theorem A.** (i) $\ell_\infty$ admits a dense subspace with an analytic renorming;
(ii) Every separable Banach space admits a dense subspace with an analytic renorming;
(iii) $\ell_1(\mathfrak{c})$ admits a dense subspace with an analytic renorming.

We notice that (iii) is particularly surprising since the corresponding result for $c_0(\omega_1)$ fails to hold (see Theorem 3.10), even though $c_0(\Gamma)$-spaces have much better smoothness properties than $\ell_1(\Gamma)$’s. Moreover, item (ii) answers positively [4, Remark 3.4], where it was asked whether, in normed spaces with countable algebraic basis, every equivalent norm can be approximated by analytic norms.

We also prove the following result.

**Theorem B.** Let $X$ be a Banach space with long unconditional Schauder basis and let $Y$ be the linear span of such basis. Then, $Y$ admits a $C^\infty$-smooth norm.

In case of $\ell_1(\Gamma)$, Theorem B solves [8] Problem 149]. Finally, in the last part of our note, we prove a variant (for dense subspaces) of a well-known Partington’s theorem [19] concerning the existence of isometric copies of $\ell_\infty(\omega_1)$ in every renorming of $\ell_\infty(\omega_1)$ (we are grateful to Gilles Godefroy for suggesting us to dig in Partington’s argument). More specifically, we prove the following theorem.

**Theorem C.** Every renorming of the space $\ell_\infty^cF(\omega_1)$ contains an isometric copy of $c_{00}(\omega_1)$.

2. Preliminaries

Let us present all the necessary background in order to avoid the reader jumping into specific references very often. The spaces we are considering throughout the paper are real normed spaces. We are following the notation from Banach space theory taken mainly from the books [1, 9, 13].

Let $X, Y$ be normed linear spaces. We say that the norm $\|\cdot\|$ of $X$ is $C^k$-smooth if its $k$th Fréchet derivative exists and is continuous at every point of $X \setminus \{0\}$. The norm is said to be $C^\infty$-smooth if this holds for every $k \in \mathbb{N}$. We denote by $\mathcal{P}^{(n)}(X; Y)$ the normed linear space of all $n$-homogeneous continuous polynomials from $X$ into $Y$. If $U \subset X$ is an open subset, then we say that a function $f : U \to Y$ is analytic if, for every $a \in U$, there exist $P_n \in \mathcal{P}^{(n)}(X; Y)$ and $\delta > 0$ such that, for all $x \in U(a, \delta)$,

$$f(x) = \sum_{n=0}^{\infty} P_n(x - a).$$

We denote by $C^\omega(U; Y)$ the vector space of all analytic functions from $U$ into $Y$. If $X, Y$ are Banach spaces over the field $\mathbb{K}$ (which can be the set of the real or complex numbers),
Let us recall that a convex set $C$ is said to be a convex body if its interior is not empty. It is well-known that every bounded symmetric convex body induces an equivalent norm on $X$ via its Minkowski functional, which is defined as

$$
\mu_B(x) := \inf\{t > 0 : x \in tB\} \quad (x \in X).
$$

Throughout the paper, we are using the following property without any explicit reference. If $B \subset C \subset (1 + \delta)B$ for some $\delta > 0$, then we have that

$$
\frac{1}{1 + \delta} \mu_B \leq \mu_C \leq \mu_B.
$$

By a renorming of a space, we understand replacing a given norm $\|\cdot\|$ on a normed space $X$ with an equivalent norm which satisfies some desired property. Let us also clarify what we mean by approximate a norm. Given a normed space $(X, \|\cdot\|)$ and $\varepsilon > 0$, we say that a new norm $\|\cdot\|_\varepsilon$-approximates $\|\cdot\|$ if

$$
\|\cdot\|_\varepsilon \leq \|\cdot\| \leq (1 + \varepsilon)\|\cdot\|_\varepsilon.
$$

In our main results, we are using the following technical lemma. The statement we are presenting here can be found essentially in [13, Chapter 5, Lemma 23]. It is worth mentioning that it concerns normed spaces and it does not require completeness.

**Lemma 2.1** (Implicit function theorem for Minkowski functionals). Let $(X, \|\cdot\|)$ be a normed space and $D$ be a nonempty open convex symmetric subset of $X$. Let $f : D \to \mathbb{R}$ be even, convex, and continuous. Suppose that there is $a > f(0)$ such that the level set $B := \{f \leq a\}$ is bounded and closed in $X$. Assume further that there is an open set $O$ with $\{f = a\} \subset O$ such that $f$ is $C^k$-smooth on $O$, where $k \in \mathbb{N} \cup \{\infty, \omega\}$. Then, the Minkowski functional $\mu$ on $B$ is an equivalent $C^k$-smooth norm on $X$.

Let us notice that, in the assumption of the previous result, the set $B$ is assumed to be a closed subset of $X$ and not merely a closed subset of $D$. Actually, $B$ being a closed subset of $D$, which is just a consequence of the continuity of $f$, would be not enough to conclude the result. Indeed, consider the space $X := \ell^\infty_2$ and let $D$ be the open unit ball of $X$. Consider $f := 2 \cdot \chi_{D^c}$, which is evidently $C^\infty$-smooth on $D$. If we set $a = 1$ and $O = \emptyset$, then $\{f \leq 1\} = D$ is not closed in $X$. On the other hand, the Minkowski functional of $B$ is the norm of $X$, which is not differentiable.

Some background on set theory is also needed. We adopt von Neumann’s definition of ordinal number as the set of its predecessors. We regard cardinal numbers as initial ordinal numbers; accordingly, we write $\omega$ for $\aleph_0$, $\omega_1$ for $\aleph_1$, etc. The cardinality of a set $A$ will be denoted $|A|$. For a cardinal $\kappa$, we denote by $\kappa^+$ the smallest cardinal number that is strictly greater than $\kappa$. Finally, given a cardinal number $\kappa$, we denote by $\text{cf} \kappa$ the cofinality of $\kappa$, that is, the smallest cardinal number $\lambda$ such that $\kappa$ can be written as a union of $\lambda$
many sets each of cardinality less than \(\kappa\). We refer to [16] or [17] for more on set-theoretical background.

In what follows we are dealing with the normed space \(\ell^c_{\infty}\), which consists of all finitely-valued sequences in \(\ell_{\infty}\). Note that it is a dense linear subspace of \(\ell_{\infty}\). Also, we consider in Section 5 the space \(\ell^c_{\infty}(\Gamma)\) of all bounded scalar-valued functions on \(\Gamma\) that are non-zero on at most countably many points in \(\Gamma\) and the dense subspace \(\ell^c_{\infty,F}(\Gamma)\) of finitely-valued sequences in \(\ell^c_{\infty}(\Gamma)\).

3. Analytic norms

In this section we show that some dense subspaces of some Banach spaces admit an analytic renorming in such a way that the new norm can be chosen to approximate the original norm of the space. As a consequence, we prove Theorem A.

**Theorem 3.1.** The space \(\ell^c_{\infty}\) admits an analytic norm that approximates \(\|\cdot\|_{\infty}\).

**Proof.** In order to prove this result, we use the Implicit functional theorem for Minkowski functionals as stated in Lemma [21]. Denote by \(x = (x(i))_{i=1}^{\infty}\) an element of \(\ell_{\infty}\) and consider the following set

\[
U := \{x \in \ell_{\infty} : \|x\|_{\infty} < 2 \text{ and } \exists j \in \mathbb{N}, q \in (0, 1) \text{ such that } |x(i)| < q, \forall i > j\}.
\]

Let us show that \(U\) is open and convex. Clearly, \(U\) is open. To see that \(U\) is convex, define, for all \(j \in \mathbb{N}\) and \(q \in (0, 1)\), the sets \(U_{j,q} := \{x \in \ell_{\infty} : \|x\|_{\infty} < 2 \text{ and } |x(i)| < q, \forall i > j\}\). Then, \((U_{j,q})_{j,q}\) is an increasing family of convex sets whose union is the whole \(U\). Thus, \(U\) is also convex.

Now, we define \(\varphi : U \rightarrow [0, \infty)\) by

\[
\varphi(x) := \sum_{i=1}^{\infty} x(i)^{2i+p} \quad (x \in U)
\]

where \(p\) is an even integer to be fixed later. Note that if \(x \in U\), then there is \(j \in \mathbb{N}\) and \(q \in (0, 1)\) such that \(|x(i)| < q\) for all \(i > j\). Thus,

\[
\sum_{i=1}^{\infty} x(i)^{2i+p} = \sum_{i=1}^{j} x(i)^{2i+p} + \sum_{i>j} x(i)^{2i+p} < \sum_{i=1}^{j} x(i)^{2i+p} + \sum_{i>j} q^{2i+p} < \infty.
\]

Therefore, \(\varphi\) is well-defined and it is analytic on \(U\) (see, e.g., [13], Chapter 1, Theorem 168).

Let \((\varepsilon_n)_{n=1}^{\infty}\) be a sequence of positive real numbers such that \(\varepsilon_1 < 1\), \(\varepsilon_{n+1} < \varepsilon_n\) for each \(n \in \mathbb{N}\), and \(\lim_{n \to \infty} \varepsilon_n = 0\). Define \(T : \ell^c_{\infty} \rightarrow \ell_{\infty}\) by \(T(x) := ((1 + \varepsilon_i)x(i))_i\) for every \(x = (x(i))_i \in \ell^c_{\infty}\). It is clear that for every \(x \in \ell^c_{\infty}\), we have

\[
(3.1) \quad \|x\|_{\infty} \leq \|T(x)\|_{\infty} \leq (1 + \varepsilon_1)\|x\|_{\infty}.
\]

Then, \(T\) is an isomorphism from \(\ell^c_{\infty}\) onto its image \(Z := T(\ell^c_{\infty})\).
We will prove that $Z$ admits an analytic norm close to $\|\cdot\|_\infty$. To do so, define $\psi := \varphi_{|Z}$. Then, $\psi$ is even, convex, and analytic in $Z$. Consider the level set $B := \{\psi \leq 1\}$. Note that $B_Z \subset U$. Indeed, if $z \in B_Z$, then there is $x \in \ell_\infty^F$ such that $T(x) = z$ and $(1 + \varepsilon_1)\|x\|_\infty = \|T(x)\|_\infty = \|z\|_\infty \leq 1$. So, $\|x\|_\infty \leq \frac{1}{1 + \varepsilon_1}$. Therefore, for every $i \geq 2$, we have

$$
|z(i)| = (1 + \varepsilon_i)|x(i)| \leq \frac{1 + \varepsilon_2}{1 + \varepsilon_1} < 1.
$$

This proves that $z \in U$ and, in particular, that $U \cap Z$ is a nonempty set. Note also that

$$
(1 - \varepsilon_1)B_Z \subset B \subset B_Z.
$$

Indeed, if $z \in B$, then $\psi(z) \leq 1$. So, $\sum_{i=1}^\infty z(i)^{2i+p} \leq 1$, which implies that $|z(i)| \leq 1$ and then $\|z\|_\infty \leq 1$. This shows that $B \subset B_Z$. On the other hand, if $z \in (1 - \varepsilon_1)B_Z$, then $\|z\|_\infty \leq 1 - \varepsilon_1$ and

$$
\psi(z) = \sum_{i=1}^\infty z(i)^{2i+p} \leq \sum_{i=1}^\infty (1 - \varepsilon_1)^{2i+p} \leq 1,
$$

if $p$ is large enough. So, $(1 - \varepsilon_1)B_Z \subset B$. In particular, $B$ is bounded. Notice also that $B$ is a closed subset of $Z$ by the lower semi-continuity of $\psi$. Now, we can apply Lemma 3.1 to get that the Minkowski functional $\mu_B$ of $B$ is an equivalent analytic norm on $Z = T(\ell_\infty^F)$. Using again (3.3), we have that it is close to $\|\cdot\|_\infty$. Finally, (3.1) allows us to pull back the analytic norm to $\ell_\infty^F$, as desired. 

By an analogous argument as in Theorem 3.1 we may prove the following statement.

**Theorem 3.2.** Let $K$ be a totally disconnected and separable compact space and let $B$ be a countable basis for the topology of $K$, consisting of clopen sets. Then the linear span of the characteristic functions of $B$ is a dense subspace of $C(K)$ that admits an analytic norm.

The next result is an extension of [10, Corollary 4].

**Theorem 3.3.** Every normed space with a countable Hamel basis admits an analytic norm that approximates the original norm of the space.

**Proof.** Let $X$ be a normed space with a countable Hamel basis. Let $(\tilde{e}_n)_{n=1}^\infty$ be a countable Hamel basis for $X$. Let us define the following system. Set $e_1 := \tilde{e}_1$. Using the Hahn-Banach theorem, pick $e_1^* \in X^*$ so that $\langle e_1^*, e_1 \rangle = 1$ and $\|e_1^*\| = 1$. Pick now $e_2 \in S_X$ to be such that $\text{span}\{e_1, e_2\} = \text{span}\{\tilde{e}_1, \tilde{e}_2\}$ and $\langle e_1^*, e_2 \rangle = 0$. Again by the Hahn-Banach theorem, pick $e_2^* \in X^*$ to be such that $\langle e_2^*, e_2 \rangle = 1$ and $\|e_2^*\| = 1$. By induction, there is $\{e_n; e_n^*\}_{n=1}^\infty \subset S_X \times S_{X^*}$ so that

$$
e_k \in \bigcap_{i<k} \ker e_i^*, \quad \langle e_k^*, e_k \rangle = 1, \quad \text{and} \quad \text{span}\{e_n : n \in \mathbb{N}\} = \text{span}\{\tilde{e}_n : n \in \mathbb{N}\}.
$$

Let us prove now that if $y = \sum_{i=1}^N \alpha_i e_i$ with $\|y\| = 1$ is an element of the linear span of $\{e_n : n \in \mathbb{N}\}$, then $|\alpha_i| \leq 2^{i-1}$ for each $i = 1, \ldots, N$. Indeed, we use induction and (3.4). Note first that

$$1 = \|y\| \geq |\langle e_1^*, y \rangle| = |\alpha_1|.$$
Now suppose that $|\alpha_i| \leq 2^{i-1}$ for every $i = 1, \ldots, N - 1$. Then, since
\[
1 = \|y\| \geq \left\langle e_N^*, \sum_{i=1}^{N} \alpha_i e_i \right\rangle = |\alpha_1 \langle e_N^*, e_1 \rangle + \alpha_2 \langle e_N^*, e_2 \rangle + \ldots + \alpha_N|,
\]
we can apply the reverse triangle inequality to get
\[
|\alpha_N| \leq 1 + |\alpha_1| + |\alpha_2| + \ldots + |\alpha_{N-1}| \leq 1 + 1 + 2 + \ldots + 2^{N-2} = 2^{N-1}.
\]
Since $X$ is separable, we can consider $X$ as a subspace of $\ell_\infty$ and the fact that $\ell_\infty^F$ is dense in $\ell_\infty$, to find, for each $n \in \mathbb{N}$ and for each $\varepsilon \in (0, 1)$, an element $x_n \in \ell_\infty^F$ such that
\[
\|x_n - e_n\|_\infty < \frac{\varepsilon}{4^n}.
\]
We will prove that there is an isomorphism between the linear spans of $\{e_n : n \in \mathbb{N}\}$ and $\{x_n : n \in \mathbb{N}\}$ by using the mapping $e_i \mapsto x_i$. Indeed, note that
\[
\left\| \sum_{i=1}^{N} \alpha_i x_i \right\| - \left\| \sum_{i=1}^{N} \alpha_i e_i \right\| \leq \left\| \sum_{i=1}^{N} \alpha_i (x_i - e_i) \right\| \leq \sum_{i=1}^{N} 2^{i-1} \|x_i - e_i\|_\infty \leq \sum_{i=1}^{\infty} \frac{\varepsilon}{2^{i+1}} < \varepsilon.
\]
By Theorem 3.1, $\ell_\infty^F$ admits an analytic equivalent norm which is close to $\|\cdot\|$ and then so does $\text{span} \{e_n : n \in \mathbb{N}\} = X$. \qed

Remark 3.4. Let us mention that a somewhat shorter proof of the above theorem is possible, by selecting a better system of coordinates in $X$. More precisely, the classical Markushevich’s theorem [18] (see, e.g., [14, Lemma 1.21]) yields us an M-basis $\{e_n; e_n^*\}_{n=1}^\infty$ such that $X = \text{span} \{e_n\}_{n=1}^\infty$. It is then sufficient to find vectors $x_n \in \ell_\infty^F$ such that
\[
\|e_n - x_n\|_\infty \cdot \|e_n^*\| \leq \varepsilon \cdot 2^{-n}
\]
and conclude as in the above proof. We decided to present the above argument, as it is self-contained and we do not really need the existence of an M-basis in the argument.

We have the following immediate consequence of Theorem 3.1.

Corollary 3.5. Let $X$ be a separable Banach space. Then there is a dense subspace $Y$ of $X$ which admits an analytic norm that approximates the original norm of $Y$.

As we pointed out in the introduction of this paper, A. Guirao, V. Montesinos, and V. Zizler asked in their recent monograph [8] the following question: if $F$ is the normed space of all finitely supported vectors in $\ell_1(\Gamma)$, with $\Gamma$ uncountable, endowed with the $\ell_1$-norm, then does $F$ admit a Fréchet smooth norm? (see [8, Problem 149]). In the next results, we are dealing with this problem and we are using Theorem 3.1 as a tool to prove them.
Theorem 3.6. The normed space \((F, \|\cdot\|_1)\) of all finitely supported vectors in \(\ell_1(c)\) admits an analytic norm that approximates \(\|\cdot\|_1\).

Proof. Since \(\ell_1(c)\) is isometric to a subspace of \(C[0,1]^*\), then \(\ell_1(c)\) is isometric to a subspace of \(\ell_\infty\). Consider \((e_\lambda)_{\lambda<\omega}\) the canonical basis of \(\ell_1(c)\). Pick \((x_\lambda)_{\lambda<\omega} \subseteq \ell_\infty^F\) to be such that \(\|x_\lambda - e_\lambda\|_\infty < \varepsilon\) for each \(\lambda\). Therefore, if the finite series \(\sum_\lambda |d_\lambda|\) is 1, then

\[
\left\| \sum d_\lambda x_\lambda \right\| - \left\| \sum d_\lambda e_\lambda \right\| \leq \sum_\lambda |d_\lambda| \|x_\lambda - e_\lambda\|_\infty < \varepsilon \sum_\lambda |d_\lambda| = \varepsilon.
\]

This means that the linear spans of \(\{e_\lambda\}_{\lambda<\omega}\) and \(\{x_\lambda\}_{\lambda<\omega}\) are isomorphic. It then follows from Theorem 3.6 that \(F = \text{span}\{e_\lambda\}_{\lambda<\omega}\) admits an analytic norm. \(\square\)

We have the following consequence of Theorem 3.6, which proves Theorem A(iii).

Corollary 3.7. Let \(S\) be a set with \(|S| = \Gamma \leq \omega\). Then, every dense subspace of \(\ell_1(S)\) contains a further dense subspace which admits an analytic norm.

Proof. Let \((e_\lambda)_{\lambda \in S}\) be the canonical basis of \(\ell_1(S)\). Then, every dense subspace of \(\ell_1(S)\) contains a subspace isomorphic to \(\text{span}\{e_\lambda\}_{\lambda \in S}\) (see [11, Theorem 2.3]). By using Theorem 3.6, every dense subspace of \(\ell_1(S)\) contains a further dense subspace which admits an analytic norm. \(\square\)

In the next theorem we shall show that the corresponding result for \(c_0(\omega_1)\) fails. Before we formulate the result, we shall record a couple of known results that we require in the proof. First, we need the following known lemma, which is a particular case of a more general result on real Fréchet differentiable functions on \(c_0(\Gamma)\) with locally uniform continuous derivatives (see [11, Corollary 8]). We present a proof for the sake of completeness.

Lemma 3.8. Let \(\Gamma\) be a set with uncountable cofinality and \(M \in \mathcal{L}_*(\omega_1)c_0(\Gamma)\) be a weakly sequentially continuous symmetric \(n\)-linear form on \(c_0(\Gamma)\). Then, \(M\) is countably supported. More precisely, there exists a countable set \(A \subseteq \Gamma\) such that

\[
M(e_{\gamma_1}, \ldots, e_{\gamma_n}) = 0 \text{ for all } \{\gamma_1, \ldots, \gamma_n\} \nsubseteq A.
\]

Proof. Suppose that for all countable set \(A \subseteq \Gamma\), there exists a finite set \(\{\gamma_1, \ldots, \gamma_n\} \nsubseteq A\) such that \(M(e_{\gamma_1}, \ldots, e_{\gamma_n}) \neq 0\). Since \(M\) is symmetric, by a slight abuse of notation, let us denote \(M(F_0) \neq 0\), where \(F_0 := \{\gamma_1, \ldots, \gamma_n\} \subseteq \Gamma\). In other words, for every countable set \(A \subseteq \Gamma\), there exists \(F_0 \nsubseteq A\) with \(|F_0| = n\) such that \(M(F_0) \neq 0\). Since this statement holds for all countable sets \(A \subseteq \Gamma\), we may choose \(F_1 \subseteq \Gamma\) with \(F_1 \nsubseteq F_0\) and \(|F_1| = n\) such that \(M(F_1) \neq 0\). Proceeding by transfinite induction, there exists \((F_\alpha)_{\alpha<\omega_1}\) with \(F_\alpha \nsubseteq \bigcup_{\xi<\alpha} F_\xi\) and \(|F_\alpha| = n\) such that \(M(F_\alpha) \neq 0\). Now, by the uncountable cofinality of \(\Gamma\), we may assume, without loss of generality, that

\[
|M(F_\alpha)| \geq \varepsilon, \quad \forall \alpha < \omega_1
\]

for some \(\varepsilon > 0\), where \(F_\alpha := \{\gamma_1^\alpha, \ldots, \gamma_n^\alpha\}\). Assuming that \((F_\alpha)_{\alpha<\omega_1}\) is a \(\Delta\)-system, by the \(\Delta\)-lemma, we can write

\[
F_\alpha = \Delta \cup \{\gamma_{k+1}^\alpha, \ldots, \gamma_n^\alpha\},
\]
where $\Delta = \{\gamma_1^0, \ldots, \gamma_n^0\}$ for some $k \leq n$ such that $\gamma_j^\alpha = \gamma_j^\beta$ for every $\alpha \neq \beta$ in $\Gamma$ with $\alpha, \beta < \omega_1$ and $j = 1, \ldots, k$. Now, let $(\alpha_j)_{j=1}^\infty$ be an injective sequence. Then, $\{(e_{\gamma_j^0}, \ldots, e_{\gamma_j^0})\}_{j}$ is weakly null in $c_0(\Gamma)^{n-k}$. Moreover, by (3.5), $|M(F_{\alpha_j})| \geq \varepsilon$. Reordering and using again that $M$ is symmetric, we have that

$$\left| M\left(e_{\gamma_1^0}, \ldots, e_{\gamma_j^0}, e_{\gamma_{k+1}^0}, \ldots, e_{\gamma_n^0}\right) \right| \geq \varepsilon.$$ 

On the other hand, by the property the set $\Delta$ satisfies and by the assumption that $M$ is weakly sequentially continuous, we have that

$$\left| M\left(e_{\gamma_1^0}, \ldots, e_{\gamma_j^0}, e_{\gamma_{k+1}^0}, \ldots, e_{\gamma_n^0}\right) \right| \to \left| M\left(e_{\gamma_1^0}, \ldots, e_{\gamma_k^0}, 0, \ldots, 0\right) \right| = 0$$

for some $(e_{\gamma_1^0}, \ldots, e_{\gamma_k^0}) \in c_0(\Gamma)^k$, which is a contradiction. \hfill \qed

**Fact 3.9.** Let $E$ be a normed space that admits an analytic norm $\|\cdot\|$. Then there exists an analytic function $f: E \to \mathbb{R}$ such that $f(0) = 0$ and $\inf f(S_E) > 1$.

**Proof.** Let $H$ be an hyperplane on $E$ and $H_1$ be an affine hyperplane obtained by translation of $H$. The function obtained by restricting $\|\cdot\|$ to $H_1$ is evidently analytic, coercive, and positive; therefore, we can find a coercive, positive, and analytic function defined on $H$. It is easy to extend such function to an analytic and coercive function on $E$; finally, the function $f$ is obtained by translation and scaling. \hfill \qed

**Theorem 3.10.** No dense subspace of $c_0(\omega_1)$ admits an analytic norm.

**Proof.** Let $E$ be a dense subspace of $c_0(\omega_1)$ and suppose by contradiction that $E$ admits an analytic norm $\|\cdot\|$. Let $f: E \to \mathbb{R}$ be a function as in the previous fact. Since $f$ is analytic on $E$, there exists $\delta > 0$ such that

$$f(x) = \sum_{n=0}^{\infty} P_n(x), \quad (x \in E, \|x\| < \delta),$$

where $P_n \in \mathcal{P}(E)$. Since each $P_n \in \mathcal{P}(E)$ is uniformly continuous on bounded sets, there exists a unique extension $\tilde{P}_n \in \mathcal{P}(c_0(\omega_1))$ with $\|P_n\|_E = \|\tilde{P}_n\|_{c_0(\omega_1)}$. By a result due to Pełczyński and Bogdanowicz, each $\tilde{P}_n$ is weakly sequentially continuous (see, for example, [13, Chapter 3, Corollary 59]) and by the Polarisation Formula (see, for example, [13, Proposition 11, Chapter 1]), so is its associated symmetric $n$-linear form $\tilde{M}_n$. Lemma 3.8 then implies that, for every $n \in \mathbb{N}_0$, there is a countable set $A_n \subseteq \Gamma$ such that for all $\{\gamma_1, \ldots, \gamma_n\} \not\subseteq A_n$, we have that $\tilde{M}_n(e_{\gamma_1}, \ldots, e_{\gamma_n}) = 0$. Again by the Polarisation Formula, we obtain that each $\tilde{P}_n$ is **countably supported** in the sense that

$$\tilde{P}_n(x) = \tilde{P}_n(x|_{A_n}) \quad (x \in c_0(\omega_1))$$

Now, by taking $A := \bigcup A_n$, we have that $A$ is still countable and $\tilde{P}_n(x) = \tilde{P}_n(x|_A)$ for every $n \in \mathbb{N}$ and every $x$ in $c_0(\omega_1)$. Therefore,

$$f(x) = f(x|_A) \quad (x \in E, \|x\| < \delta).$$
Now, since $E$ is dense in $c_0(\omega_1)$, we may choose $x \in E$ such that $\|x\| = 1$ and $\|x\|_{A} < \varepsilon$, where $\varepsilon > 0$ is very small. By the continuity of $f$, the value $f(x|_{A})$ must be small as well. On the other hand, we have that $f(x) \geq \inf f(S_{E}) > 1$, which gives us the desired contradiction. \hfill \Box

4. $C^\infty$-smoothness

This section is dedicated to the construction of smooth norms in presence of an unconditional basis; in particular, the main result of the section readily implies Theorem B. Before we proceed, we need to recall one definition (see, e.g., [13 §7.3]). A set $\{e_\gamma\}_{\gamma \in \Gamma}$ in a Banach space $X$ is called an unconditional Schauder basis of $X$ if for every $x \in X$ there is a unique family of real numbers $\{a_\gamma\}_{\gamma \in \Gamma}$ such that $x = \sum_{\gamma \in \Gamma} a_\gamma e_\gamma$ in the following sense: for every $\varepsilon > 0$, there is a finite subset $F \subseteq \Gamma$ such that

$$\left\| x - \sum_{\gamma \in G} a_\gamma e_\gamma \right\| < \varepsilon,$$

whenever $F \subseteq G$. If $\{e_\gamma\}_{\gamma \in \Gamma}$ is an unconditional basis of $X$ and $A$ is a subset of $\Gamma$, then there is a naturally defined bounded linear projection $P_A$ from $X$ onto $\overline{\text{span}}\{e_\gamma\}_{\gamma \in A}$ defined by $P_A(x) = \sum_{\gamma \in A} \langle e_\gamma^*, x \rangle e_\gamma$. The number $\sup_{A \subseteq \Gamma} \| P_A \|$ is called the suppression constant of the basis; accordingly, a basis is suppression 1-unconditional when $\sup_{A \subseteq \Gamma} \| P_A \| = 1$.

**Theorem 4.1.** Let $X$ be a Banach space with a suppression 1-unconditional Schauder basis $\{e_\gamma\}_{\gamma \in \Gamma}$ and set $Y := \text{span}\{e_\gamma\}_{\gamma \in \Gamma}$. Then, $Y$ is a dense subspace of $X$ which admits a $C^\infty$-smooth norm that approximates the original one.

**Proof.** Let $\{e_\gamma\}_{\gamma \in \Gamma}$ be a suppression 1-unconditional Schauder basis for the Banach space $(X, \| \cdot \|)$ and set $Y := \text{span}\{e_\gamma\}_{\gamma \in \Gamma}$. We shall start by fixing some parameters. Let $(\varepsilon_k)_{k=0}^\infty$ be a strictly decreasing sequence of positive real numbers such that

$$\varepsilon_k \downarrow 0 \quad \text{and} \quad \frac{1 + \varepsilon_{k+1}}{1 + \varepsilon_k} > 1.$$  \hfill (4.1)

Now, let $(\theta_k)_{k=0}^\infty$ be another decreasing sequence of positive real numbers such that

$$\theta_k \downarrow 0 \quad \text{and} \quad \frac{1 + \varepsilon_{k+1}}{1 + \varepsilon_k} < 1 - 2\theta_{k+1} \quad \text{for every} \quad k \geq 0.$$  \hfill (4.2)

For each finite subset $A \subseteq \Gamma$, we have that $P_A(X)$ is a finite-dimensional Banach space and therefore, we can pick a $C^\infty$-smooth norm $\| \cdot \|_{(s),A}$ on $P_A(X)$ such that

$$\frac{1}{1 + \theta_{|A|}} \| \cdot \| \leq \| \cdot \|_{(s),A} \leq \| \cdot \|.$$  \hfill (4.3)

We are now in position to define the following norm $\| \cdot \|_f$ on $Y$:

$$\| x \|_f := \sup_{|A| < \omega} (1 + \varepsilon_{|A|}) \cdot \| P_A(x) \| \quad (x \in Y).$$
Let us notice that this new norm approximates the original one:

\[(4.4) \quad \|\cdot\| \leq \|\cdot\|_f \leq (1 + \varepsilon_1) \|\cdot\|.\]

Moreover, for every \(x \in Y\), we clearly have

\[\|x\|_f = \max_{A \subseteq \text{supp} x} (1 + \varepsilon_{|A|}) \cdot \|P_A(x)\|.\]

We shall now prove that the above maximum is, indeed, locally attained in a strong sense. More precisely, we prove the following claim.

**Claim 4.2.** Let \(x \in Y\) be such that \(\|x\|_f \leq 1\). Set \(n = |\text{supp} x|\) and consider the open neighbourhood \(O_x\) of \(x\) given by

\[O_x := \{y \in Y : \|y - x\|_f < \theta_{n+1}\}.\]

Then, for each \(y \in O_x\) and \(A \not\subseteq \text{supp} x\) we have

\[(4.5) \quad (1 + \varepsilon_{|A|}) \cdot \|P_A(y)\|_{(s,A)} \leq 1 - \theta_{|A|}.\]

**Proof of Claim 4.2.** We start proving the following stronger estimate, valid for the vector \(x\) and for every \(A \not\subseteq \text{supp} x\):

\[(4.6) \quad (1 + \varepsilon_{|A|}) \|P_A(x)\| \leq \begin{cases} 
\frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|A|-1}}, & \text{if } |A| \leq n, \\
\frac{1 + \varepsilon_{n+1}}{1 + \varepsilon_n}, & \text{if } |A| > n.
\end{cases}\]

Indeed, set \(B := \text{supp} x\) and take any \(A \not\subseteq B\). Notice that we may assume \(A \cap B \neq \emptyset\) since, otherwise, \((4.6)\) is trivially true. Since \(\|x\|_f \leq 1\), we have

\[(1 + \varepsilon_{|A|}) \|P_A(x)\| = \frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|A \cap B|}} (1 + \varepsilon_{|A \cap B|}) \|P_{A \cap B}(x)\| \leq \frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|A \cap B|}} \|x\|_f \leq \frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|A \cap B|}}.

Assume first that \(|A| \leq n\). Since \(A \not\subseteq B\), we have \(|A \cap B| \leq |A| - 1\); thus, since \((\varepsilon_k)_{k=0}^\infty\) is decreasing,

\[(1 + \varepsilon_{|A|}) \|P_A(x)\| \leq \frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|A \cap B|}} \leq \frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|A|-1}},\]

which proves the first part of \((4.6)\). On the other hand, if \(|A| > n\), then, using again that \((\varepsilon_k)_{k=0}^\infty\) is decreasing and that \(|B| = n\), we have

\[(1 + \varepsilon_{|A|}) \|P_A(x)\| \leq \frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|A \cap B|}} \leq \frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|B|}} \leq \frac{1 + \varepsilon_{n+1}}{1 + \varepsilon_n} = \frac{1 + \varepsilon_{n+1}}{1 + \varepsilon_n}.

Therefore, \((4.6)\) is proved.
We now pass to the proof of (4.5). Given any \( y \in O_x \) and any finite set \( A \) with \( A \not\subseteq \text{supp } x \), we have:

\[
(1 + \varepsilon_{|A|}) \| P_A(y) \|_{(s),A} \leq (1 + \varepsilon_{|A|}) \| P_A(y) \| \leq (1 + \varepsilon_{|A|}) \| P_A(x) \| + (1 + \varepsilon_{|A|}) \| P_A(y - x) \|
\]

\[
\leq (1 + \varepsilon_{|A|}) \| P_A(x) \| + \| y - x \|_f < (1 + \varepsilon_{|A|}) \| P_A(x) \| + \theta_{n+1}.
\]

If \( |A| \leq n \), then

\[
(1 + \varepsilon_{|A|}) \| P_A(y) \|_{(s),A} < (1 + \varepsilon_{|A|}) \| P_A(x) \| + \theta_{n+1} \overset{(4.6)}{\leq} \frac{1 + \varepsilon_{|A|}}{1 + \varepsilon_{|A|-1}} + \theta_{|A|} \overset{4.2}{\leq} 1 - \theta_{|A|}.
\]

On the other hand, if \( |A| > n \),

\[
(1 + \varepsilon_{|A|}) \| P_A(y) \|_{(s),A} \overset{(4.6)}{\leq} \frac{1 + \varepsilon_{n+1}}{1 + \varepsilon_n} + \theta_{n+1} \overset{4.2}{\leq} 1 - \theta_{n+1} \leq 1 - \theta_{|A|}.
\]

We first prove that \( \Psi \) is (real-valued and) \( C^\infty \)-smooth on the open set \( O \) defined by

\[
O := \bigcup \{ O_x : x \in Y, \| x \|_f \leq 1 \}.
\]

Indeed, we actually show that \( \Psi \) is locally expressed by a finite sum on \( O \) (whence the claim follows, since every summand is plainly \( C^\infty \)-smooth). Pick \( x \in Y \) with \( \| x \|_f \leq 1 \) and let \( y \in O_x \). Then, for every finite set \( A \) with \( A \not\subseteq \text{supp } x \), (4.5) yields us

\[
(1 + \varepsilon_{|A|})(1 + \theta_{|A|}) \| P_A(x) \|_{(s),A} \leq (1 + \theta_{|A|})(1 - \theta_{|A|}) = 1 - \theta_{|A|}^2,
\]

which implies that \( \rho_{|A|} \left( (1 + \varepsilon_{|A|})(1 + \theta_{|A|}) \| P_A(x) \|_{(s),A} \right) = 0 \). This shows that, on the open set \( O_x \), only the finitely many terms with \( A \subseteq \text{supp } x \) give a non-zero contribution to \( \Psi \).

Moreover, we note that

\[
(4.7) \quad \left\{ x \in Y : \| x \|_f \leq \frac{1 - \theta_{|A|}}{1 + \theta_{|A|}} \right\} \subseteq \{ \Psi \leq 1 \} \subseteq \{ x \in Y : \| x \|_f \leq 1 \} \subseteq O.
\]

Indeed, the last inclusion is immediate by the definition of the set \( O \). If we take \( x \in Y \) with \( \Psi(x) \leq 1 \), then we have that \( \rho_{|A|} \left( (1 + \varepsilon_{|A|})(1 + \theta_{|A|}) \| P_A(x) \|_{(s),A} \right) \leq 1 \) for every finite set \( A \). By the properties of the functions \( \rho_n \), we then get \( (1 + \varepsilon_{|A|})(1 + \theta_{|A|}) \| P_A(x) \|_{(s),A} \leq 1 \). Therefore, by (4.3),

\[
1 \geq (1 + \varepsilon_{|A|})(1 + \theta_{|A|}) \| P_A(x) \|_{(s),A} \geq (1 + \varepsilon_{|A|}) \| P_A(x) \|,
\]
which implies that $\|x\|_f \leq 1$. This shows the inclusion $\{\Psi \leq 1\} \subseteq \{\|\cdot\|_f \leq 1\}$. Finally, if $x \in Y$ satisfies $\|x\|_f \leq \frac{1-\theta_1}{1+\theta_1}$, then, for every finite set $A$,

$$(1 + \varepsilon_{|A|})(1 + \theta_{|A|})\|P_A(x)\|_{(s),A} \leq (1 + \varepsilon_{|A|})(1 + \theta_{|A|})\|P_A(x)\| \leq \frac{1-\theta_1}{1+\theta_1}(1 + \theta_{|A|}) \leq 1 - \theta_1 \leq 1 - \theta_2^2.$$ 

So, we actually showed that if $x \in Y$ satisfies $\|x\|_f \leq \frac{1-\theta_1}{1+\theta_1}$, then $\Psi(x) = 0$.

For the last part of the proof, we would like to adjust all the information we have so far in order to apply Lemma 2.1. Consider the convex set $D := \{\Psi < 1\}$; by (4.7), we know that $D \subseteq \mathcal{O}$, whence $D$ is an open set in $Y$. Moreover, $\Psi$ is even, convex, and $C^\infty$-smooth on $D$. (Notice that we cannot apply Lemma 2.1 directly to the set $\mathcal{O}$, since it is not a priori clear that $\mathcal{O}$ is convex.) Also, the level set $\{\Psi \leq 1 - \theta_1\}$ is a closed subset of $Y$, by the lower semi-continuity of $\Psi$. Therefore, we can apply Lemma 2.1 which assures us that the Minkowski functional $\|\cdot\|$ of $\{\Psi \leq 1 - \theta_1\}$ is an equivalent $C^\infty$-smooth norm on $Y$.

Finally, by using the previous observations and (4.7), we get that

$$\|\cdot\|_f \leq \|\cdot\| \leq \frac{1 + \theta_1}{1 - \theta_1} \|\cdot\|_f;$$

combining with (4.4), we conclude that $\|\cdot\|$ is a $C^\infty$-smooth norm on $Y$ which approximates $\|\cdot\|$, as desired. 

As a particular case of Theorem 4.1, we have the following corollary.

**Corollary 4.3.** The linear span of the canonical basis of $\ell_p(\Gamma)$ ($1 \leq p < \infty$) admits a $C^\infty$-smooth norm.

In the case $p = 1$, we can argue as in the proof of Corollary 3.7 and obtain the following stronger result.

**Corollary 4.4.** Every dense subspace of $\ell_1(\Gamma)$ contains a further dense subspace which admits a $C^\infty$-smooth norm.

## 5. Proof of Theorem C

**Theorem 5.1.** Let $\Gamma$ be a cardinal number with $\text{cf}\,\Gamma \geq \omega_1$. Then, every renorming of $\ell_{c,\infty}^c(\Gamma)$ contains an isometric copy of $\ell_{c,\infty}^c(\Gamma)$.

As a particular case of the result, every renorming of $\ell_{c,\infty}^c(S)$ contains an isometric copy of $c_{00}(\omega_1)$, whenever $S$ is an uncountable set. Therefore, we arrive at the following corollary.

**Corollary 5.2.** $\ell_{c,\infty}^c(S)$ does not admit a Gâteaux differentiable norm, whenever $S$ is an uncountable set.

In the proof of Theorem 5.1 we shall need the following standard lemma, a straightforward consequence of a representation theorem for $\ell_{c,\infty}(S)^*$; we also give a simple, self-contained proof, for the sake of completeness.
Lemma 5.3. For every \( \varphi \in (\ell_\infty(S))^* \), there is a countable set \( A \subseteq S \) such that \( \langle \varphi, x \rangle = 0 \) for every \( x \in \ell_\infty(S) \) such that \( \text{supp } x \cap A = \emptyset \).

Proof. If \( S \) is countable, the result is trivially true, as we can take \( A = S \); we then assume that \( S \) is uncountable. Arguing by contradiction, assume that, for every countable subset \( A \) of \( S \), it is possible to find a unit vector \( x \in \ell_\infty(S) \) with \( \langle \varphi, x \rangle > 0 \) and \( \text{supp } x \cap A = \emptyset \).

By an obvious transfinite induction argument, we then obtain a disjointly supported long sequence \((x_\alpha)_{\alpha < \omega_1}\) of unit vectors such that \( \langle \varphi, x_\alpha \rangle > 0 \), for each \( \alpha < \omega_1 \). Therefore, up to passing to an uncountable subset and relabeling, we can also assume that \( \langle \varphi, x_\alpha \rangle > \delta \), for some \( \delta > 0 \) and every \( \alpha < \omega_1 \). This is, however, impossible: indeed, for every \( N \in \mathbb{N} \),

\[
1 \geq \left\| \sum_{j=0}^{N} x_j \right\|_\infty \geq \left( \varphi, \sum_{j=0}^{N} x_j \right) \geq \delta N,
\]

a contradiction. \( \square \)

Corollary 5.4. Let \( \|\cdot\| \) be any equivalent norm on \( \ell_\infty(S) \). Then, for every \( w \in \ell_\infty(S) \), there exists a countable subset \( A \subseteq S \) such that \( \text{supp } w \subseteq A \) and

\[
\|w + u\| \geq \|w\|
\]

for every \( u \in \ell_\infty(S) \) with \( \text{supp } u \cap A = \emptyset \).

Proof. Indeed, let \( w \in \ell_\infty(S) \). Then, by the Hahn-Banach theorem, there is \( \varphi \in (\ell_\infty(S))^* \) with \( \|\varphi\|_* = 1 \) and such that \( \langle \varphi, w \rangle = \|w\| \). Consider the countable set \( A \subseteq S \) obtained applying Lemma 5.3 to \( \varphi \). Then, for every \( u \in \ell_\infty(S) \) such that \( \text{supp } u \cap A = \emptyset \),

\[
\|w + u\| \geq \langle \varphi, w + u \rangle = \langle \varphi, w \rangle = \|w\|.
\]

Finally, since \( \text{supp } w \) is countable, we can also assume \( \text{supp } w \subseteq A \), and we are done. \( \square \)

Proof of Theorem 5.1. Let \( \|\cdot\| \) be an equivalent norm in \( \ell_\infty^c(\Gamma) \) and consider the set

\[
\mathcal{U} := \{ x \in \ell_\infty^c(\Gamma) : x(\gamma) \in \{0, \pm1\} \text{ for each } \gamma \in \Gamma \}.
\]

Evidently, \( \mathcal{U} \subseteq \ell_\infty^c(\Gamma) \); moreover, although \( \mathcal{U} \) is not a linear subspace, \( u \pm v \in \mathcal{U} \) whenever \( u, v \in \mathcal{U} \) are disjointly supported.

Claim 5.5. For every subset \( S \) of \( \Gamma \) with \( |S| = \Gamma \), there exist a vector \( V \in \mathcal{U} \) and a countable subset \( F \) of \( S \) with \( \text{supp } V \subseteq F \) such that

\[
\|V + u\| = \|V\|
\]

for every \( u \in \mathcal{U} \) with \( \text{supp } u \subseteq S \setminus F \).

Proof of Claim 5.5. Fix a sequence \((\varepsilon_j)_{j=0}^\infty\) of positive scalars with \( \varepsilon_j \searrow 0 \); also, select \( v_0 \in \mathcal{U} \). By Corollary 5.4, there exists a countable set \( A_0 \subseteq S \) with \( \text{supp } v_0 \subseteq A_0 \) such that \( \|v_0 + u\| \geq \|v_0\| \) for every \( u \in \mathcal{U} \) with \( \text{supp } u \subseteq S \setminus A_0 \). We then set

\[
\alpha_0 := \sup \{ \|v_0 + u\| : u \in \mathcal{U}, \text{supp } u \subseteq S \setminus A_0 \};
\]

we can now pick a vector \( v_1 \in \mathcal{U} \) with \( \text{supp } v_1 \subseteq S \setminus A_0 \) and such that \( \|v_0 + v_1\| \geq \alpha_0 - \varepsilon_0 \). We then repeat the above argument. Corollary 5.4 applied to the vector \( v_0 + v_1 \), yields us
a countable set $A_1 \subseteq S$ with $\text{supp}(v_0 + v_1) \subseteq A_1$ and such that $\|v_0 + v_1 + u\| \geq \|v_0 + v_1\|$ for every $u \in \mathcal{U}$ with $\text{supp } u \subseteq S \setminus A_1$. Of course, we can assume without loss of generality that $A_0 \subseteq A_1$. Next, we define

$$\alpha_1 := \sup \{\|v_0 + v_1 + u\| : u \in \mathcal{U}, \text{supp } u \subseteq S \setminus A_1\}.$$ 

If we continue by induction, we obtain a sequence of vectors $(v_j)_{j=0}^\infty \subseteq \mathcal{U}$ and an increasing sequence of countable subsets $(A_j)_{j=0}^\infty$ of $S$ such that, upon setting

$$\alpha_n := \sup \{\|v_0 + \cdots + v_n + u\| : u \in \mathcal{U}, \text{supp } u \subseteq S \setminus A_n\},$$

we have:

- (i) $\text{supp } v_n \subseteq A_n$;
- (ii) $\text{supp } v_{n+1} \cap A_n = \emptyset$;
- (iii) $\|v_0 + \cdots + v_n + v_{n+1}\| \geq \alpha_n - \varepsilon_n$;
- (iv) $\|v_0 + \cdots + v_n + u\| \geq \|v_0 + \cdots + v_n\|$, for every $u \in \mathcal{U}$ with $\text{supp } u \subseteq S \setminus A_n$.

Indeed, once we have found $v_0, \ldots, v_n$ and $A_0, \ldots, A_n$ with the above properties, by definition of $\alpha_n$, we can find $v_{n+1} \in \mathcal{U}$ with $\text{supp } v_{n+1} \subseteq S \setminus A_n$ and such that

$$\|v_0 + \cdots + v_n + v_{n+1}\| \geq \alpha_n - \varepsilon_n.$$ 

This gives (ii) and (iii). Then, we apply Corollary 5.4 to the vector $v_0 + \cdots + v_{n+1}$ and we find a countable subset $A_{n+1}$ of $S$ for which (i) and (iv) hold. We can also assume $A_n \subseteq A_{n+1}$, which concludes the induction step.

By (i) and (ii), the vectors $v_j$ are disjointly supported; therefore the series $\sum_{j=0}^\infty v_j$ is pointwise convergent and the vector $V := \sum_{j=0}^\infty v_j$ is a well-defined element of $\mathcal{U}$. Moreover, for every $n \in \mathbb{N}$, the support of $\sum_{j=n+1}^\infty v_j$ is contained in $S \setminus A_n$, whence $\|V\| \geq \|v_0 + \cdots + v_n\|$, by (iv).

We are now in position to define the forbidden set $F$. By Corollary 5.4, we can choose a countable set $B$ such that $\text{supp } V \subseteq B$ and $\|V + u\| \geq \|V\|$ for every $u \in \mathcal{U}$ with $\text{supp } u \subseteq S \setminus B$. We then set $F := \cup_{j=0}^\infty A_j \cup B$.

Finally, fix $u \in \mathcal{U}$ with $\text{supp } u \subseteq S \setminus F$. On the one hand, $\|V + u\| \geq \|V\|$, since $\text{supp } u \subseteq S \setminus B$. On the other one, for every $n \in \mathbb{N}$, the vector $u + \sum_{j=n+1}^\infty v_j$ is supported in $S \setminus A_n$, whence the definition of $\alpha_n$ and (iii) imply

$$\|V + u\| = \left\|v_0 + \cdots + v_n + \left(u + \sum_{j=n+1}^\infty v_j\right)\right\| \leq \alpha_n \leq \|v_0 + \cdots + v_n + v_{n+1}\| + \varepsilon_n \leq \|V\| + \varepsilon_n.$$ 

Letting $n \to \infty$ yields $\|V + u\| = \|V\|$ and concludes the proof of the claim. \hfill \square

Having the claim at our disposal, we can find by transfinite induction vectors $(V_\alpha)_{\alpha < \Gamma} \subseteq \mathcal{U}$ and countable disjoint sets $(F_\alpha)_{\alpha < \Gamma}$ with $\text{supp } V_\alpha \subseteq F_\alpha$ such that

$$\|V_\alpha + u\| = \|V_\alpha\| \text{ for every } u \in \mathcal{U} \text{ with } \text{supp } u \cap \left(\bigcup_{\beta < \alpha} F_\beta\right) = \emptyset.$$
Indeed, having found $(V_\alpha)_{\alpha<\gamma}$ and $(F_\alpha)_{\alpha<\gamma}$, for some $\gamma < \Gamma$, we apply Claim 5.5 to the set $\Gamma \setminus (\cup_{\alpha<\gamma} F_\alpha)$ and obtain the desired vector $V_\gamma$ and countable set $F_\gamma$. (In the case $\gamma = 0$, we just apply the claim to $S = \Gamma$.)

If we select any increasing sequence $(\alpha_j)_{j=0}^\infty$ of ordinals, with $\alpha_j < \Gamma$ for each $j$, and signs $(\varepsilon_j)_{j=0}^\infty \subseteq \{\pm 1\}$, it is clear that the vector $\sum_{j=1}^\infty \varepsilon_j V_{\alpha_j}$ belongs to $U$ and its support is disjoint from $\cup_{\beta\leq \alpha_0} F_\beta$ (once more, the convergence of the above series is intended in the pointwise sense). Therefore,

\[
\left\| \sum_{j=0}^\infty \varepsilon_j V_{\alpha_j} \right\| = \| V_{\alpha_0} \|.
\]

In particular, $\| V_\alpha \pm V_\beta \| = \| V_\alpha \|$ when $\alpha < \beta < \Gamma$, whence $\| V_\beta \| \leq \frac{1}{2} \| V_\alpha + V_\beta \| + \frac{1}{2} \| V_\alpha - V_\beta \| = \| V_\alpha \|$. By the uncountable cofinality of $\Gamma$, the non-increasing function $\alpha \mapsto \| V_\alpha \|$ ($\alpha < \Gamma$) is therefore eventually constant; consequently, up to discarding some initial terms and relabeling, we can assume that there exists $c \in (0, \infty)$ with $\| V_\alpha \| = c$, for each $\alpha < \Gamma$.

From (5.1) we can now infer that, for every increasing sequence $(\alpha_j)_{j=0}^\infty$ of ordinals smaller than $\Gamma$ and signs $(\varepsilon_j)_{j=0}^\infty \subseteq \{\pm 1\}$, we have

\[
\left\| \sum_{j=0}^\infty \varepsilon_j V_{\alpha_j} \right\| = c.
\]

A standard convexity argument then assures us that, for every finitely valued sequence $(c_j)_{j=0}^\infty$ of scalars, one has

\[
\left\| \sum_{j=0}^\infty c_j V_{\alpha_j} \right\| = \max_{j=0,\ldots,\infty} |c_j|.
\]

Therefore, the rule

\[
\ell_\infty^c (\Gamma) \ni (c_\alpha)_{\alpha<\Gamma} \mapsto \sum_{\alpha<\Gamma} c_\alpha V_\alpha
\]

defines an isometric embedding of $\ell_\infty^c (\Gamma)$ into $(\ell_\infty^c (\Gamma), \| \cdot \|)$, which concludes the proof. \qed
