With unseasonably warm weather during the entire count period (17 December 1994 through 2 January 1995) it seemed less like Christmas than it has for a number of years. The southwest portion of the province was completely without snow while other areas, even though snow covered, were loosing snow depth to the warm weather. The 88 counts completed this year were one less than last year and, in spite of the warm weather, the number of people participating dropped from 605 in 1993 to 597 this year. With the reduction in both the number of counts and participants a corresponding drop was inevitable in the number of hours accumulated — 1,006 compared to 1,120 last year.

Weather and Coverage

Table 1 summarizes the weather conditions reported on the counts. As indicated, the temperatures were unseasonably mild, with the average overnight low being -10°C and the daytime highs averaged -5°C. Turtle Lake had the dubious honour of having the coldest night at -30°C while Coronach basked in the mid-afternoon sun at +12°C. The heaviest snow cover was reported from the east side — Hudson Bay reported the most with almost a metre on the ground. Many locations were without any snow. The average snow depth for the entire province was only 11 cm. Saskatchewan is noted for its windy weather but, as with everything else, the wind was a pleasant surprise — there was virtually none, with an average overall of only 8 kmph, which by Saskatchewan standards is almost dead calm.

The Birds

There were 94 species recorded on count day, with an additional four species during the count period giving an overall total of 98 species, the same as last year. The results are compiled in Tables 3, 4 and 5. The total number of birds seen totalled 112,685 individuals, higher than the almost 100,00 seen in 1990. The most abundant species was again the Snow Bunting with a total of 28,730 individuals reported. Surprisingly, the second most common species was the Mallard (26,168) which stayed in record numbers in the south where the lack of snow allowed them to continue to feed in the fields. House Sparrow (18,077), Bohemian Waxwing (11,382), Rock Dove (6,772), Canada Goose (3,491), Black-billed Magpie (3,319) and Black-capped Chickadee rounded out the list of species which exceeded 2,000 individuals on the counts.

Population trends of some of the most common species are provided in Table 7. The most substantial increases were for the semi-hardy species which linger longer when conditions are mild. Golden-crowned Kinglets experienced the biggest increase (1,423%). This is most encouraging and continues the general upward trend in their numbers since the massive winter die off in the late 1970s. Next on the list was Mallard (1,019%). Other species
which fit the semi-hardy category and had large increases were Northern Flicker (430%), Brown Creeper (236%), American Tree Sparrow (328%) and Red-winged Blackbird (289%). One species which one would have expected to increase with the lack of snow is the Horned Lark, but it actually decreased. Whether the decrease is real or an artifact of the birds feeding in the open fields instead of on the road¬sides, which is the case when the fields are covered in snow, remains to be seen.

Grouse populations generally improved with both Ruffed and Spruce Grouse continuing upwards on track with their normal cyclic trends. Northern Goshawks which normally parallel the grouse populations were very scarce. Forest owls were virtually non-existent, with only single Great Gray and Hawk Owls and no Barred, Boreal or Saw-whets.

The lack of cones on the spruce trees was undoubtedly a factor in the decline in numbers of Red-breasted Nuthatch and both crossbill species. White-winged Crossbills were not even found during count day and appear only as an additional species.

Of the winter finches, only Pine Grosbeaks were present in good numbers, showing an overall increase. Redpolls and Evening Grosbeaks were less common, particularly the redpolls (Hoary Redpolls were absent from counts completely).

Rare Species

For the second year in a row, no new species were added to the all-time list. Table 4 lists the least frequent species on the counts and the rarest species are all in this table. The first Willow Ptarmigan in a number of years were found on the McMahon Lakes count. It is not that this species is necessarily rare but a fact that few counts are carried out far enough north to find this species. Of the truly rare, the Varied Thrushes found at both Fort Walsh and Whitewood rank among the best. The Rufous-sided Towhee found at Skull Creek was only the fourth count record and follows two separate occurrences from last year. American Goldfinches were found in both Prince Albert and Saskatoon.

House Finches were reported from five separate counts, phenomenal considering they were a new species only two years ago. It is becoming obvious that the cold extremes of our winters are not going to stop the spread of this species which has expanded rapidly westward from eastern North America in the past ten years.

Table 6 provides a summary of new high counts recorded for species during the 1994 count. The Mallard high was 50% higher than the previous with over 15,000 seen at the Cookson Reservoir on the Coronach count. This same count turned in new records for Gadwall (3) and American Coot (23). Both eagle species had new records with 79 Bald Eagles at Squaw Rapids (19 in one tree!!!) and 17 Golden Eagles on the Grassland National Park count. The 22 Northern Flickers at Saskatchewan were more than twice the previous high and the 11 Pileated Woodpeckers at Kamsack almost three times the previous high. Finally, of note were the 393 Common Ravens at Hudson Bay, many of which were at the garbage dump.

Count Areas and Participants
