Abstract

We propose a complex extension of $\mu T$ permutation antisymmetry in the neutrino Majorana matrix $M_\nu$. The latter can be realized for the Lagrangian by appropriate CP transformations on the neutrino fields. The resultant form of $M_\nu$ is shown to be simply related to that with a complex (CP) extension of $\mu T$ permutation symmetry, with identical phenomenological consequences, though their group theoretic origins are quite different. We investigate those consequences in detail for the minimal seesaw induced by two strongly hierarchical right-chiral neutrinos $N_1$ and $N_2$ with the result that the Dirac phase is maximal while the two Majorana phases are either 0 or $\pi$. We further provide an uptodate discussion of the $\beta\beta_0\nu$ process vis-a-vis ongoing and forthcoming experiments. Finally, a thorough treatment is given of baryogenesis via leptogenesis in this scenario, primarily with the assumption that the lepton asymmetry produced by the decays of $N_1$ only matters here with the asymmetry produced by $N_2$ being washed out. Tight upper and lower bounds on the mass of $N_1$ are obtained from the constraint of obtaining the correct observed range of the baryon asymmetry parameter and the role played by $N_2$ is elucidated thereafter. The mildly hierarchical right-chiral neutrino case (including the quasidegenerate possibility) is discussed in an Appendix.

1 Introduction

The masses and mixing properties [1] of the three light neutrinos continue to intrigue. We now know within reasonably precise ranges their two squared mass differences while from cosmology a fairly tight upper bound [2] of 0.23 eV has emerged on the sum of the three masses.

*rome.samanta@saha.ac.in
†probirrana@gmail.com
‡ambar.ghosal@saha.ac.in
The atmospheric mixing angle is now pinned around its maximal value of $\pi/4$ and the solar mixing angle around the tri-bimaximal value while the reactor mixing angle is known to be significantly nonzero and close to $8^0$. The current trend of the data [3] suggests that the Dirac CP phase could be close to $3\pi/2$ but a definitive statement is yet to emerge. A specific prediction on the value of the latter will be very welcome. It is not known yet whether the light neutrinos are Dirac or Majorana in nature while relentless searches for the decisive neutrinoless double $\beta$ decay signal continue. For the latter case the two Majorana phases of the neutrinos also need to be predicted. Light Majorana neutrino masses can be generated by the seesaw mechanism [4] and a minimal version [5] with just two heavy right-chiral (RH) neutrinos seems especially attractive. Further, the formulation of a viable scheme of baryogenesis via leptogenesis within this scenario is a challenging task. There has also been a substantial amount of work with discrete flavor symmetries of the light neutrino Majorana mass matrix: specifically real $\mu\tau$ permutation symmetry [6] and its complex (CP) extension [7] as well as real $\mu\tau$ permutation antisymmetry [8] but not the complex (CP) extension of that. This last mentioned topic will be the subject of our attention in this paper with the aim of predicting the neutrino CP phases.

The neutrino mass terms in the Lagrangian density read

$$-L_{\nu}^\text{mass} = \frac{1}{2} \bar{\nu}_{Ll}^C (M_\nu)_{lm} \nu_{Lm} + \text{h.c.} \quad (1.1)$$

with $\nu_{Ll}^C = C \nu_{Ll}^T$ and the subscripts $l,m$ spanning the lepton flavor indices $e$, $\mu$, $\tau$ while the subscript $L$ denotes left-chiral neutrino fields. $M_\nu$ is a complex symmetric matrix ($M_\nu^* \neq M_\nu = M_\nu^T$) in lepton flavor space. It can be put into a diagonal form by a similarity transformation with a unitary matrix $U$:

$$U^T M_\nu U = M_\nu^d \equiv \text{diag} (m_1, m_2, m_3). \quad (1.2)$$

Here $m_i (i = 1, 2, 3)$ are real and we assume that $m_i \geq 0$. We work in the basis in which charged leptons are mass diagonal. We are motivated by a flavor-based model constructed by Mohapatra and Nishi [12], which could accommodate a diagonal charged lepton mass matrix as well as a CP-transformed $\mu\tau$ interchange symmetry. Now we can relate $U$ to the $PMNS$ mixing matrix $U_{PMNS}$:

$$U = P_\phi U_{PMNS} \equiv P_\phi \begin{pmatrix}
    c_{12}c_{13} & e^{i\frac{\delta}{2}}s_{12}c_{13} & s_{13}e^{-i(\delta - \frac{\phi}{2})} \\
    -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & e^{i\frac{\phi}{2}}(c_{12}c_{23} - s_{12}s_{13}s_{23}e^{i\delta}) & c_{13}s_{23}e^{i\frac{\phi}{2}} \\
    s_{12}s_{23} - c_{12}c_{13}c_{23}e^{i\delta} & e^{i\frac{\phi}{2}}(-c_{12}s_{23} - s_{12}s_{13}s_{23}e^{i\delta}) & c_{13}c_{23}e^{i\frac{\phi}{2}}
\end{pmatrix} \quad (1.3)$$

where $P_\phi = \text{diag} (e^{i\phi_1}, e^{i\phi_2}, e^{i\phi_3})$ is an unphysical diagonal phase matrix and $c_{ij} \equiv \cos \theta_{ij}$, $s_{ij} \equiv \sin \theta_{ij}$ with the mixing angles $\theta_{ij} = [0, \pi/2]$. We work within the PDG convention [9] but denote our Majorana phases by $\alpha$ and $\beta$. CP-violation enters through nontrivial values of the Dirac phase $\delta$ and of the Majorana phases $\alpha, \beta$ with $\delta, \alpha, \beta = [0, 2\pi]$. 

Real $\mu\tau$ symmetry [6] for $M_\nu$ implies that

$$G^T M_\nu G = M_\nu,$$  \hspace{1cm} (1.4)

where $G$ is a generator of a $Z_2$ symmetry effecting $\mu\tau$ interchange. In the neutrino flavor space $G$ has the form

$$G = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}. \hspace{1cm} (1.5)$$

A substantial amount of phenomenological work has been done following the consequences of (1.4). Additionally, its possible group theoretic origin from a more fundamental symmetry such as $A_4$ have been investigated [10]. However, this flavor symmetry leads to the prediction that $\theta_{13} = 0$ which has now been excluded at more than $5.2\sigma$ [11]. A way out was proposed [7] in terms of its complex (CP) extension (CP$^{\mu\tau}$) with the postulate

$$G^T M_\nu G = M_\nu^\ast.$$

(1.6)

The above can be realized as a Lagrangian symmetry by means of a CP transformation on the neutrino fields as

$$\nu_{Ll} \rightarrow iG_{lm} \gamma^0 \nu_{Lm}^C,$$  \hspace{1cm} (1.7)

where $l, m$ are flavor indices and $\nu_{Lm}^C = C\bar{\nu}_{Lm}^T$. Detailed phenomenological consequences of (1.6) have been investigated in Ref. [12].

Let us move on to real $\mu\tau$ permutation antisymmetry [8] which proposes that

$$G^T M_\nu G = -M_\nu.$$  \hspace{1cm} (1.8)

Note that the antisymmetry condition in (1.8) can written as a symmetry condition

$$G^T M_\nu G = M_\nu,$$  \hspace{1cm} (1.9)

where $G = iG$. Now $G$ is a generator of $Z_4$ symmetry since $G^4 = 1$. A sizable amount of work has earlier been done using [13] the real $\mu\tau$ antisymmetry idea – including its application to the neutrino masses and mixing as well as its possible group theoretic origin from a more fundamental flavor symmetry such as $A_5$. However, the major phenomenological problem with exact real $\mu\tau$ antisymmetry is that it leads to a maximal solar neutrino mixing angle $\theta_{12} = \pi/4$ as well as two degenerate light neutrinos – in conflict with experiment [14]. Perturbative modifications, in attempts to address these problems, unfortunately lead to a proliferation of extra unknown parameters. It is therefore highly desirable to propose an extension of this symmetry which is exact and therefore has the beauty of minimizing the number of input parameters.
This is what we aim to do in this paper by proposing a complex (CP) extension of $\mu \tau$ flavor antisymmetry $\text{CP}^{\mu \tau A}$ and working out its various phenomenological implications. Complex extensions of $\mu \tau$ symmetry [7] and scaling symmetry [15] as well as their consequences have been worked out earlier. That is the direction of our thrust here for $\mu \tau$ antisymmetry.

We consider a complex (CP) extension of $\mu \tau$ antisymmetry ($\text{CP}^{\mu \tau A}$) in the neutrino mass matrix. We show that this extension leads to a form of $M_\nu$ which is very simply related to that of $M_\nu$ for the CP$^{\mu \tau}$ case. Moreover, this form allows neutrino mixing angles that are perfectly compatible with experiment both for a normal and for an inverted mass ordering. Additionally, specific statements can be made on CP violation in the neutrino sector. The Majorana phases $\alpha$ and $\beta$ have to be 0 or $\pi$ while Dirac CP violation has to be maximal with the phase $\delta$ being either $\pi/2$ or $3\pi/2$. Further, reasonably nondegenerate values for the three neutrino masses can be generated by incorporating the minimal seesaw mechanism [5] implemented through two heavy right-chiral neutrinos $N_{R\ell}$ ($\ell = 1, 2$) with a $2 \times 2$ Majorana matrix $M_R$. (In case there is a third heavy Majorana neutrino, that is assumed to be much heavier and hence totally decoupled). Definitive predictions can be made on neutrinoless double beta decay for both types of mass ordering. Finally, a realistic scenario of baryogenesis via leptogenesis can be drawn and an acceptable value of the baryon asymmetry parameter $Y_B$ can be derived. Though the phenomenological consequences of $M_\nu^{\text{CP}^{\mu \tau}}$ and $M_\nu^{\text{CP}^{\mu \tau A}}$ are identical, we feel that an uptodate detailed discussion of these along with some new results related to the scenario of baryogenesis via leptogenesis will be useful.

The new features in our work are (i) the demonstration that $M_\nu^{\text{CP}^{\mu \tau A}}$ and $M_\nu^{\text{CP}^{\mu \tau}}$ have identical phenomenological consequences despite their origin from different residual symmetries ($Z_4$ and $Z_2$ respectively) and (ii) the use of the minimal seesaw with two heavy righthanded neutrinos (and consequently one massless left handed neutrino) to explore those consequences - in particular $\beta\beta 0\nu$ decay and baryogenesis via leptogenesis. Let us highlight here what we propose to do in this paper. We plan to discuss the complex (CP) extension of $\mu \tau$ antisymmetry which has been analyzed so far in literature with its perturbative modifications only. Then we shall show how the resultant $M_\nu^{\text{CP}^{\mu \tau A}}$ is simply related to $M_\nu^{\text{CP}^{\mu \tau}}$ – the neutrino Majorana mass matrix from the complex (CP) extension of $\mu \tau$ symmetry – with identical phenomenological consequences despite the fact that their respective real components have almost entirely different predictions. We further emphasize the fact that CP$^{\mu \tau}$ and CP$^{\mu \tau A}$ are implemented with different residual symmetry generators, namely $Z_2$ and $Z_4$ respectively. Thus the corresponding high energy theory for these residual CP symmetries would likely be different. We then work out the consequences of CP$^{\mu \tau A}$ in the framework of a minimal seesaw which leads to a vanishing value of one of the light neutrino masses and a very constraint range of the sum of the light neutrino masses as well. We also make an uptodate comparison of our conclusions on $\beta\beta 0\nu$ decay with ongoing and forthcoming searches. We shall do a full
parameter scan of the $3 \times 2$ Dirac mass matrix $m_D$ in the minimal seesaw scenario using the uptodate neutrino oscillation $3\sigma$ global fit data. This in turn will lead us to perform a detailed computation related to the process baryogenesis via leptogenesis in our work which will result in new interesting upper and lower bounds on the mass of $N_1$. We shall also stress that these bounds could be erased if we consider a mildly hierarchical RH neutrino spectrum. We shall discuss the effect of $N_2$ on the final baryon asymmetry $Y_B$, in particular on the obtained upper and lower bounds on $M_1$ from the standard $N_1$ decay scenario.

The rest of the paper is organized as follows. In Section 2 we explain the above mentioned complex extension $\text{CP}^{\mu\tau A}$. Section 3 contains a discussion of how the neutrino mixing angles and CP violating phases originate from $\text{CP}^{\mu\tau A}$. In Section 4 we discuss the origin of the neutrino masses from the minimal seesaw mechanism. The phenomenon of neutrinoless double beta decay is treated in Section 5. In Section 6 we discuss baryogenesis via leptogenesis. Constraints on our model parameter space from all these phenomena are derived by numerical analysis in Section 7. The final Section 8 contains a discussion of our conclusions. In an Appendix we discuss what happens to our results if the right handed neutrinos are mildly hierarchical or quasidegenerate in mass.

## 2 Complex extension of $\mu\tau$ antisymmetry

We propose a complex extension of (1.8), namely

$$G^T M_\nu G = -M_\nu^*, \quad G^T M_\nu G = M_\nu^*. \quad (2.1)$$

The complex invariance condition in (2.1) can be obtained by the means of a CP transformation [16] on the neutrino fields as

$$\nu_{Ll} \rightarrow i G_{lm} \gamma^0 \nu^C_{Lm}. \quad (2.2)$$

As we will see, since the real part of the resultant complex matrix exhibits $\mu\tau$ antisymmetry, we call the implemented CP symmetry as a complex extended $\mu\tau$ antisymmetry or simply complex $\mu\tau$ antisymmetry. This complex $\mu\tau$ antisymmetry $\text{CP}^{\mu\tau A}$, generated by $G$, needs to be broken in the charged lepton sector. Given that our charged lepton mass matrix $M_\ell$ is diagonal, a replacement of $M_\nu$ by $M_\ell$ in (2.1) would immediately lead to the unacceptable result $m_\mu = m_\tau$. There is an additional desirable reason for breaking $\text{CP}^{\mu\tau A}$ in $M_\ell$. A nonzero Dirac CP violation is equivalent to

$$\text{Tr} [H_\nu, H_\ell]^3 \neq 0, \quad (2.3)$$

where the hermitian combinations are introduced as $H_\nu = M_\nu^\dagger M_\nu$, $H_\ell = M_\ell^\dagger M_\ell$ [17]. A common CP symmetry $G$ in both the sectors would imply

$$G^T H_\nu^T G^* = H_\nu, \quad G^T H_\ell^T G^* = H_\ell. \quad (2.4)$$
From (2.4) it follows that $\text{Tr}[H_\nu, H_\ell]^3 = 0$ which leads to $\sin \delta = 0$ i.e. a vanishing Dirac CP violation. Though this is still a possibility, it goes against the current trend of the data [3]. The most general structure of $M_\nu$ that satisfies the CP\mbox{$\mu\tau$A} condition (2.1) can be worked out to be

$$M_{\nu}^{\text{CP}\mu\tau\text{A}} = \begin{pmatrix} iA & B & -B^* \\ B & C & iD \\ -B^* & iD & -C^* \end{pmatrix},$$ \hspace{1cm} (2.5)$$

where $A, D$ are real and $B, C$ are complex mass dimensional quantities which are a priori unknown. The matrix $M_{\nu}^{\text{CP}\mu\tau\text{A}}$ can also be written as

$$M_{\nu}^{\text{CP}\mu\tau\text{A}} = \begin{pmatrix} 0 & B_1 & -B_1 \\ B_1 & C_1 & 0 \\ -B_1 & 0 & -C_1 \end{pmatrix} + i \begin{pmatrix} A & B_2 & B_2 \\ B_2 & C_2 & D \\ B_2 & D & C_2 \end{pmatrix},$$ \hspace{1cm} (2.6)$$

where $B = B_1 + iB_2$ and $C = C_1 + iC_2$ with $B_{1,2}$ and $C_{1,2}$ being real. Note that the real part of the matrix in (2.6) is invariant under $\mu\tau$ antisymmetry while the imaginary part is $\mu\tau$ symmetric. Thus the entire source of corrections here to real $\mu\tau$ antisymmetry arises from the imaginary $\mu\tau$ symmetric part.

Here we make the interesting observation that $iM_{\nu}^{\text{CP}\mu\tau\text{A}}$ yields a neutrino Majorana mass matrix that is complex $\mu\tau$ symmetric since

$$iM_{\nu}^{\text{CP}\mu\tau\text{A}} = \begin{pmatrix} -A & iB & -iB^* \\ iB & iC & -D \\ -iB^* & -D & -iC^* \end{pmatrix} \equiv M_{\nu}^{\text{CP}\mu\tau\text{A}}.$$

This is since

$$G^T (iM_{\nu}^{\text{CP}\mu\tau\text{A}}) G = (iM_{\nu}^{\text{CP}\mu\tau\text{A}})^*.$$ \hspace{1cm} (2.7)$$

Therefore the phenomenological consequences of a complex (CP) $\mu\tau$ symmetric form of $M_\nu$ and a complex antisymmetric form of the same would be identical. Nevertheless, we deem it worthwhile to give a detailed updated discussion of its phenomenological consequences and highlight some new effects such as the role of another heavy RH neutrino $N_2$ on the process of baryogenesis via leptogenesis in a standard $N_1$-leptogenesis scenario.

3 Neutrino mixing angles and phases from $M_{\nu}^{\text{CP}\mu\tau\text{A}}$

Eqs. (1.2) and (2.1) together imply [7] that

$$G U^* = U \bar{d},$$ \hspace{1cm} (3.1)$$
\[ \tilde{d}_{lm} = \pm \delta_{lm}. \]  

(3.2)

Let us take
\[ \tilde{d} = \text{diag} (\tilde{d}_1, \tilde{d}_2, \tilde{d}_3), \]

(3.3)

where each \( \tilde{d}_i \) (\( i = 1, 2, 3 \)) can be +1 or −1. Eq. (3.1) can explicitly be written, by taking \( G \) equal to \( i \) times \( G \) as given in (1.5), namely
\[
\begin{pmatrix}
  iU^*_{e_1} & iU^*_{e_2} & iU^*_{e_3} \\
  iU^*_{\tau_1} & iU^*_{\tau_2} & iU^*_{\tau_3} \\
  iU^*_{\mu_1} & iU^*_{\mu_2} & iU^*_{\mu_3}
\end{pmatrix} =
\begin{pmatrix}
  \tilde{d}_1 U_{e_1} & \tilde{d}_2 U_{e_2} & \tilde{d}_3 U_{e_3} \\
  \tilde{d}_1 U_{\mu_1} & \tilde{d}_2 U_{\mu_2} & \tilde{d}_3 U_{\mu_3} \\
  \tilde{d}_1 U_{\tau_1} & \tilde{d}_2 U_{\tau_2} & \tilde{d}_3 U_{\tau_3}
\end{pmatrix}
\]

(3.4)

which is equivalent to six independent equations:
\[ iU^*_{e_1} = \tilde{d}_1 U_{e_1}, iU^*_{e_2} = \tilde{d}_2 U_{e_2}, iU^*_{e_3} = \tilde{d}_3 U_{e_3}. \]

(3.5)

\[ iU^*_{\tau_1} = \tilde{d}_1 U_{\mu_1}, iU^*_{\tau_2} = \tilde{d}_2 U_{\mu_2}, iU^*_{\tau_3} = \tilde{d}_3 U_{\mu_3}. \]

(3.6)

In order to calculate the Majorana phases in a way that avoids the unphysical phases, it is useful to construct two rephasing invariants [18]
\[ I_1 = U_{e_1} U_{e_2}^*, I_2 = U_{e_1} U_{e_3}^*. \]

(3.7)

By using (3.5), \( I_{1,2} \) can be written as free of the unphysical phases, namely
\[ I_1 = \tilde{d}_1 \tilde{d}_2 U_{e_1} U_{e_2}, I_2 = \tilde{d}_1 \tilde{d}_3 U_{e_1} U_{e_3}. \]

(3.8)

After equating the two different expressions for \( I_{1,2} \) in (3.7) and (3.8), we obtain
\[ I_1 = c_{12} s_{12} c_{13}^2 e^{-i\frac{\beta}{2}} = \tilde{d}_1 \tilde{d}_2 c_{12} s_{12} c_{13}^2 e^{i\frac{\beta}{2}}, \]

(3.9)

\[ I_2 = c_{12} s_{13} c_{13} e^{i(\delta - \frac{\beta}{2})} = \tilde{d}_1 \tilde{d}_3 c_{12} s_{13} c_{13} e^{-i(\delta - \frac{\beta}{2})}. \]

(3.10)

Eqs.(3.9) and (3.10) imply
\[ e^{i\alpha} = \tilde{d}_1 \tilde{d}_2, e^{2i(\delta - \beta/2)} = \tilde{d}_1 \tilde{d}_3 \]

(3.11)

Thus
\[ \tilde{d}_1 \tilde{d}_2 = +1 \Rightarrow \alpha = 0, \quad \tilde{d}_1 \tilde{d}_2 = -1 \Rightarrow \alpha = \pi, \]

(3.12)

\[ \tilde{d}_1 \tilde{d}_3 = +1 \Rightarrow \delta - \frac{\beta}{2} = 0, \quad \tilde{d}_1 \tilde{d}_3 = -1 \Rightarrow \delta - \frac{\beta}{2} = \pi/2. \]

(3.13)
Taking the modulus squared of the third equality in (3.6), namely $|U_{\tau 3}| = |U_{\mu 3}|$, we obtain

$$c_{23}^2 = s_{23}^2$$

(3.14)

which implies $\theta_{23} = \pi/4$, i.e. a maximal atmospheric mixing. Incorporating this last result, the modulus square of the first or the second equality in (3.6) leads after some algebra to the relation

$$2c_{12}s_{12}c_{13}s_{13}\cos \delta = 0.$$  

(3.15)

Given the experimentally observed nonvanishing values for all the mixing angles, (3.15) leads to a maximal Dirac CP-violation

$$\cos \delta = 0 \text{ i.e. } \delta = \pi/2 \text{ or } 3\pi/2.$$  

(3.16)

It then follows from (3.13) that

$$\tilde{d}_1 \tilde{d}_3 = +1 \Rightarrow \beta = \pi, \tilde{d}_1 \tilde{d}_3 = -1 \Rightarrow \beta = 0.$$  

(3.17)

We can summarize our results on $\alpha$, $\beta$ and $\cos \delta$ in Table 1.

| $\tilde{d}_1$ | $\tilde{d}_2$ | $\tilde{d}_3$ | $\tilde{d}_1 \tilde{d}_2$ | $\tilde{d}_1 \tilde{d}_3$ | $\alpha$ | $\beta$ | $\cos \delta$ |
|---|---|---|---|---|---|---|---|
| 1 | 1 | 1 | 1 | 1 | 0 | $\pi$ | 0 |
| 1 | -1 | 1 | -1 | 1 | $\pi$ | $\pi$ | 0 |
| 1 | 1 | -1 | 1 | -1 | 0 | 0 | 0 |
| 1 | -1 | -1 | -1 | -1 | $\pi$ | 0 | 0 |

Table 1: Predictions on the CP phases

4 Origin of neutrino masses from a minimal seesaw

We now discuss the realization of the complex extended $\mu\tau$ antisymmetric mass matrix $M_{\nu\mu\tau}^{CP}$ through the minimal seesaw mechanism [5] mentioned earlier. This mechanism makes use of two heavy right chiral neutrino fields $N_{Ri} (i = 1, 2)$ with a Majorana mass matrix $M_R$. We work in a basis in which $M_R$ is real, positive and diagonal [19], i.e., $M_R = \text{diag}(M_1, M_2)$, $M_{1,2} > 0$. With $m_D$ as the Dirac mass matrix, the neutrino mass terms read

$$L_{\nu,N}^{mass} = \bar{N}_{Ri}(m_D)_{\alpha \alpha} l_{\alpha \alpha}^L + \frac{1}{2} \tilde{N}_{Ri}(M_R)_{ij} \delta_{ij} N_{Rj}^C + \text{h.c.},$$

(4.1)

where $l_{\alpha \alpha} = \begin{pmatrix} \nu_{\alpha L} \\ e_{\alpha L} \end{pmatrix}^T$ is the SM lepton doublet of flavor $\alpha$. The effective light neutrino mass matrix is given by the standard seesaw relation

$$M_\nu = -m_D^T M_R^{-1} m_D.$$  

(4.2)
In this case (2.1) is satisfied through the symmetry transformation on \( m_D \) as
\[
m_D \mathcal{G} = -im_D^*,
\] (4.3)
so long as \( M_R^{-1} \) is real. The most general form of \( m_D \) that satisfies (4.3) can be parametrized as
\[
m_D = \begin{pmatrix}
\sqrt{2}a_1 e^{i\pi/4} & b_1 e^{i\theta_1} & ib_1 e^{-i\theta_1} \\
\sqrt{2}a_2 e^{i\pi/4} & b_2 e^{i\theta_2} & ib_2 e^{-i\theta_2}
\end{pmatrix},
\] (4.4)
where the parameters \( a_{1,2}, b_{1,2} \) and \( \theta_{1,2} \) are real.

The form of the effective light neutrino mass matrix \( M_\nu \) that now emerges is given below:
\[
M_{\nu}^{CP\&\mu\tau A} = \begin{pmatrix}
-2i(x_1^2 + x_2^2) & -\sqrt{2}e^{i\pi/4}(x_1 y_1 e^{i\theta_1} + x_2 y_2 e^{i\theta_2}) & -i\sqrt{2}e^{i\pi/4}(x_1 y_1 e^{-i\theta_1} + x_2 y_2 e^{-i\theta_2}) \\
-\sqrt{2}e^{i\pi/4}(x_1 y_1 e^{i\theta_1} + x_2 y_2 e^{i\theta_2}) & -(e^{2i\theta_1} y_1^2 + e^{2i\theta_2} y_2^2) & -i(y_1^2 + y_2^2) \\
-i\sqrt{2}e^{i\pi/4}(x_1 y_1 e^{-i\theta_1} + x_2 y_2 e^{-i\theta_2}) & -i(y_1^2 + y_2^2) & e^{-2i\theta_1} y_1^2 + e^{-2i\theta_2} y_2^2
\end{pmatrix}.
\] (4.5)

In (4.5) we have introduced new real parameters \( x_{1,2} \) and \( y_{1,2} \) which are obtained by scaling \( a_{1,2} \) and \( b_{1,2} \) with the square roots of the respective RH neutrino masses \( M_{1,2} \), i.e.
\[
\frac{a_{1,2}}{\sqrt{M_{1,2}}} = x_{1,2}, \quad \frac{b_{1,2}}{\sqrt{M_{1,2}}} = y_{1,2}.
\] (4.6)

The lightest neutrino mass, either \( m_1 \) for a normal mass ordering or \( m_3 \) for an inverted mass ordering, has to vanish since \( \det M_{\nu}^{CP\&\mu\tau A} = 0 \). Furthermore, one of the phases of \( M_\nu \) (say \( \theta_1 \)) can be rotated by the phase matrix \( P_\phi = \text{diag} \left( 1, e^{i\phi}, e^{-i\phi} \right) \) with the choice \( \theta_1 = -\phi \). Thus we are left with only the phase difference \( \theta_2 - \theta_1 \) in \( M_\nu \). We can now rename \( \theta_2 - \theta_1 \) as \( \theta \). Without loss of generality, this is also equivalent to the choice \( \theta_1 = 0 \) and \( \theta_2 = \theta \) in \( m_D \). From now on we shall use this redefined phase \( \theta \) for both \( M_\nu \) and \( m_D \).

## 5 Neutrinoless double beta decay

The rare \( \beta\beta0\nu \) process can arise from the following decay of of a nucleus
\[
(A, Z) \rightarrow (A, Z + 2) + 2e^-.
\] (5.1)
In (5.1) lepton number is violated by two units. Unlike in neutrinoful double \( \beta \)–decay, which is a sequence of two single \( \beta \)–decays, final state neutrinos are absent in the \( \beta\beta0\nu \) process. The latter can go through via an appropriate neutrino loop only if the light neutrinos have
Majorana masses. Therefore any observation of such a decay will unambiguously establish the Majorana nature of the light neutrinos. The half-life, corresponding to $\beta\beta$ decay, can be expressed as

$$\frac{1}{T_{1/2}} = G |M_{ee}|^2 |M| m_e^{-2}. \quad (5.2)$$

Here $G$ is the two-body phase space factor and $M_{ee}$ is the $(1,1)$ element of the effective light neutrino mass matrix $M_\nu$, cf.(1.1). Moreover, $M$ is the nuclear matrix element (NME) and $m_e$ is the electron mass. $M_{ee}$ can be written within our convention as

$$M_{ee} = c_{12}^2 c_{13}^2 m_1 + s_{12}^2 c_{13}^2 m_2 e^{i\alpha} + s_{13}^2 m_3 e^{i(\beta - 2\delta)}. \quad (5.3)$$

Significant upper limits on $|M_{ee}|$ are available from ongoing search experiments for $\beta\beta$ decay. KamLAND-Zen [20] and EXO [21] had earlier constrained this value to be $< 0.35$ eV. But the most impressive upper bound till date is provided by GERDA phase-II data [22]: $M_{ee} < 0.098$ eV. As explained in Sec.3, we have four sets of values for the three CP violating phases $\alpha, \beta, \delta$ in the neutrino sector corresponding to the four independent $\tilde{d}$ matrices. Furthermore, we need to consider both kinds of light neutrino mass ordering: normal and inverted. Thus we shall have eight sets of predictions for $|M_{ee}|$ from our modelled $M_\nu$. These will be detailed in our section on numerical analysis.

At this stage it may be useful to point out how (5.3) simplifies in our model for the specific cases of normal and inverted mass ordering subject to the condition given in eqn.(3.16). For a normal mass ordering, we have $m_1 = 0$ and further

$$\alpha = 0, \beta = 0; \quad |M_{ee}| = (s_{12}^4 c_{13}^4 m_2^2 + s_{13}^2 m_3^2 - 2s_{12}^2 s_{13}^2 c_{13} m_2 m_3)^{1/2} \quad \text{(Normal)}, \quad (5.4)$$

$$\alpha = 0, \beta = \pi; \quad |M_{ee}| = (s_{12}^4 c_{13}^4 m_2^2 + s_{13}^2 m_3^2 + 2s_{12}^2 s_{13}^2 c_{13} m_2 m_3)^{1/2} \quad \text{(Normal)}, \quad (5.5)$$

Note that the value of $|M_{ee}|$ becomes somewhat less here since the terms involving $m_3$ are suppressed by the powers of $s_{13}$. For an inverted mass ordering, $m_3 = 0$ and $|M_{ee}|$ becomes independent of $\beta$ and $\delta$. Indeed, we have

$$\alpha = 0; \quad |M_{ee}| = c_{13}^2 \left(c_{12}^4 m_1^2 + s_{12}^4 m_2^2 + 2c_{12}^2 s_{12}^2 m_1 m_2\right)^{1/2} \quad \text{(Inverted)}, \quad (5.6)$$

$$\alpha = \pi; \quad |M_{ee}| = c_{13}^2 \left(c_{12}^4 m_1^2 + s_{12}^4 m_2^2 - 2c_{12}^2 s_{12}^2 m_1 m_2\right)^{1/2} \quad \text{(Inverted)}. \quad (5.7)$$

Since $\Delta m_{21}^2 << |\Delta m_{32}^2|$, in this case we can assume $m_1 \approx m_2 \approx \sqrt{|\Delta m_{32}^2|}$. Thus, for the two allowed values of $\alpha$, we have

$$\alpha = 0; \quad |M_{ee}| \approx \sqrt{|\Delta m_{32}^2|} c_{13}^2 \quad \text{(Inverted)}, \quad (5.8)$$

$$\alpha = \pi; \quad |M_{ee}| \approx \sqrt{|\Delta m_{32}^2|} c_{13}^2 \left(1 - 2\sin^2 \theta_{13}\right)^2 \quad \text{(Inverted)}. \quad (5.9)$$

We see that $|M_{ee}|$ for $\alpha = \pi$ is suppressed here relative to its value in the $\alpha = 0$ case.
6 Baryogenesis via leptogenesis

To start with, we recall the observed range of $Y_B = (n_B - n_{\bar{B}})/s$ – the ratio of baryonic minus antibaryonic number density to the entropy density – namely

$$8.55 \times 10^{-11} < Y_B < 8.77 \times 10^{-11}.$$ (6.1)

CP violating decays from heavy Majorana neutrinos that are out of equilibrium generate a lepton asymmetry [23–25]. The latter is later converted into a baryon asymmetry by sphaleron transitions [26]. The appropriate part of the Lagrangian for the process can be written as

$$-\mathcal{L} = \lambda_{i\alpha} \bar{N}_{Ri} \phi \gamma^\dagger_l l_{L\alpha} + \frac{1}{2} \bar{N}_{Ri} (M_R)_{ij} \delta_{ij} N_{Cj} + \text{h.c.},$$ (6.2)

where $\phi = i\tau_2 \phi^*$, with $\phi = \begin{pmatrix} \phi^+ & \phi^0 \end{pmatrix}^T$ being the Higgs doublet. The possible decays of $N_i$ from (6.2) are $N_i \rightarrow e^\alpha \phi^+ + \nu_{\alpha} \phi^0$, $e^\alpha \phi^- + \nu_{\alpha} \phi^0$, $e^\alpha + \nu_{\alpha} \phi^0$. The CP asymmetry parameter $\varepsilon_i^\alpha$, that is a measure of the required CP violation, arises from the interference between the tree level, one loop self energy and one loop vertex diagrams [23] for the decay of $N_i$. It has the general expression [27]

$$\varepsilon_i^\alpha = \frac{1}{4\pi^2 h_{ii}} \sum_{j \neq i} \left\{ \text{Im}[h_{ij}(m_D)_{i\alpha}(m_D^*)_{j\alpha}]g(x_{ij}) + \frac{\text{Im}[h_{ij}(m_D)_{i\alpha}(m_D^*)_{j\alpha}]}{1-x_{ij}} \right\},$$ (6.3)

where $h_{ij} \equiv (m_D m_D^*)_{ij}$, $\langle \phi^0 \rangle = v/\sqrt{2}$ (so that $m_D = v\lambda/\sqrt{2}$) and $x_{ij} = M_j^2/M_i^2$. In addition, the loop function $g(x_{ij})$ has the standard expression

$$g(x_{ij}) = \frac{\sqrt{x_{ij}}}{1-x_{ij}} + f(x_{ij})$$ (6.4)

with

$$f(x_{ij}) = \sqrt{x_{ij}} \left[ 1 - (1 + x_{ij}) \ln \left( \frac{1+x_{ij}}{x_{ij}} \right) \right].$$ (6.5)

Before proceeding further in the calculation of $\varepsilon_i^\alpha$ in our scenario, we need to address some important issues related to leptogenesis. For hierarchical RH neutrino masses $M_2 \gg M_1$ (some discussion of the mildly hierarchical RH neutrino case including quasidegenerate masses is given later in the Appendix), it can be shown that only the decays of $N_1$ matter for the creation of lepton asymmetry while the latter created from the heavier neutrinos gets washed out [28] significantly. Therefore, in general, only $\varepsilon_1^\alpha$ is the pertinent quantity in a hierarchical leptogenesis scenario. Nevertheless, there are certain circumstances in which the decays of $N_{2,3}$ do affect the final baryon asymmetry [31, 32]. Furthermore, flavor plays an important role in the phenomenon of leptogenesis [29, 30]. Assuming the temperature scale of the process to be $T \sim M_1$, the rates of the charged lepton Yukawa interaction categorize leptogenesis into the following three categories.
1) **Unflavored leptogenesis**: $T \sim M_1 > 10^{12}$ GeV, when all interactions with all flavors are out of equilibrium: In this case all the flavors are indistinguishable; therefore the total CP asymmetry is a sum over all flavors, i.e. $\varepsilon_1 = \sum_\alpha \varepsilon_1^\alpha$ and the final baryon asymmetry $Y_B$ is proportional to $\varepsilon_1$.

2) **$\tau$-flavored leptogenesis**: $10^9$ GeV $< T \sim M_1 < 10^{12}$ GeV, when only the $\tau$ flavor is in equilibrium and hence distinguishable. In this regime there are two pertinent CP asymmetry parameters; $\varepsilon_1^\tau$ and $\varepsilon_1^{(2)} = \varepsilon_1^e + \varepsilon_1^\mu$. The final baryon asymmetry $Y_B$ may be approximated as [29]

$$Y_B \approx -\frac{12}{37g^*} \left[ \varepsilon_1^{(2)} \eta \left( \frac{417}{589} \tilde{m}_2 \right) + \varepsilon_1^\tau \eta \left( \frac{390}{589} \tilde{m}_\tau \right) \right], \quad (6.6)$$

where the washout masses $\tilde{m}_{2,\tau}$ and $\varepsilon_1^{(2)}$ are defined as

$$\tilde{m}_2 = M_1^{-1} \left( |(m_D)_{1e}|^2 + |(m_D)_{1\mu}|^2 \right), \quad \tilde{m}_\tau = M_1^{-1} |(m_D)_{1\tau}|^2, \quad \varepsilon_1^{(2)} = \sum_{\alpha = e,\mu} \varepsilon_1^\alpha = \varepsilon_1^e + \varepsilon_1^\mu. \quad (6.7)$$

In order to know the nature of the washout processes, it is convenient to define two washout parameters $K_{2,\tau} = \tilde{m}_{2,\tau}/10^{-3}$ relevant to this mass regime. Further, $\eta(\tilde{m}_2)$ and $\eta(\tilde{m}_\tau)$ are the efficiency factors that account for the inverse decay and the lepton number violating scattering processes while $g^*$ is the number of relativistic degrees of freedom in the thermal bath having a value $g^* \approx 106.75$ in the SM.

3) **Fully flavored leptogenesis**: $T \sim M_1 < 10^9$ GeV, when in addition to the $\tau$ flavor, the $\mu$ flavor is also in equilibrium – thus all the three flavors are distinguishable. Again for the evaluation of the final baryon asymmetry $Y_B$ in this regime, we make use of the approximate analytic formula for $Y_B$ presented in Ref. [29]. In the $T \sim M_1 < 10^9$ GeV regime, $Y_B$ is well approximated by

$$Y_B \approx -\frac{12}{37g^*} \left[ \varepsilon_1^e \eta \left( \frac{151}{179} \tilde{m}_e \right) + \varepsilon_1^\mu \eta \left( \frac{344}{537} \tilde{m}_\mu \right) + \varepsilon_1^\tau \eta \left( \frac{344}{537} \tilde{m}_\tau \right) \right], \quad (6.8)$$

where the washout masses $\tilde{m}_\alpha$ are defined as

$$\tilde{m}_\alpha = \frac{|(m_D)_{1\alpha}|^2}{M_1}, \quad \alpha = e,\mu,\tau. \quad (6.9)$$

We now focus on the calculation of the quantities related to the leptogenesis in our model. The flavor sum over $\alpha$ leads the first term in the RHS of (6.3) to be proportional to $\text{Im}(h_{ij})^2$ and the second term to vanish. This is since

$$\sum_\alpha \text{Im}[h_{ji}(m_D)_{1\alpha}(m_D^*_{1\alpha})] = \text{Im}[h_{ji}h_{ij}] = \text{Im}[h_{ji}h_{ji}^*] = \text{Im}|h_{ji}|^2 = 0. \quad (6.10)$$

In fact, in our model the matrix $h = m_D m_D^\dagger$ is real as given by

$$h = \begin{pmatrix} 2(a_1^2 + b_1^2) & 2(a_1a_1 + b_1b_2 \cos \theta) \\ 2(a_1a_1 + b_1b_2 \cos \theta) & 2(a_2^2 + b_2^2) \end{pmatrix}. \quad (6.11)$$
Therefore the flavor summed CP asymmetry parameter \( \varepsilon_1 = \sum_\alpha \varepsilon_1^\alpha \) vanishes, i.e., unflavored leptogenesis does not occur in this complex (CP) extended \( \mu \tau \) antisymmetry scheme. Using (4.4) and (6.3), the flavored CP asymmetries can be calculated to be

\[
\varepsilon_1^\mu = 0, \quad \varepsilon_1^\tau = -\frac{g'(x_{12})}{4\pi v^2} \left[ \frac{(a_1 a_2 + b_1 b_2 \cos \theta) b_1 b_2 \sin \theta}{a_1^2 + b_1^2} \right] = -\varepsilon_1^\tau, \tag{6.12}
\]

where \( g'(x_{12}) \) is given by

\[
g'(x_{12}) = g(x_{12}) + (1 - x_{12})^{-1}. \tag{6.13}
\]

It is useful to simplify (6.13) for a hierarchical RH neutrino scheme to

\[
g'(M_2^2/M_1^2) = -\frac{3 M_1}{2 M_2} - \frac{M_1^2}{M_2^2}. \tag{6.14}
\]

Now in our minimal seesaw scheme, assuming a specific hierarchy of the RH neutrino masses, namely \( M_2/M_1 \approx 10^3 \), the final \( Y_B \) is calculated from (6.12), (6.6) and (6.8) to be

\[
Y_B \approx \frac{12}{37 g^*} \varepsilon_1^\mu \left[ \eta \left( \frac{390}{589} \bar{m}_\tau \right) - \eta \left( \frac{417}{589} \bar{m}_2 \right) \right], \tag{6.15}
\]

for the \( \tau \)-flavored regime and

\[
Y_B \approx \frac{12}{37 g^*} \varepsilon_1^\mu \left[ \eta \left( \frac{344}{537} \bar{m}_\tau \right) - \eta \left( \frac{344}{537} \bar{m}_\mu \right) \right], \tag{6.16}
\]

for the fully flavored regime.

In our primary analysis, the effect of the heavy neutrino \( (N_2) \) on the produced final baryon asymmetry has been neglected with the assumption that the asymmetry produced by the decays of \( N_2 \) get washed out [28]. We now give a brief discussion on how the heavy neutrino \( N_2 \) can affect the final baryon asymmetry \( Y_B \). As elaborated below, there are two ways in which the effect of \( N_2 \) might arise: indirect and direct. We first discuss the indirect effect. Though the neutrino oscillation data are fitted with the rescaled parameters of (4.6), in order to compute the quantities related to leptogenesis such as \( \varepsilon_1^\alpha \), we need to evaluate the parameters of the Dirac mass matrix elements. Given a set of rescaled parameters, the latter can be generated by varying \( M_{1,2} \) in (4.6). It is thus interesting to see whether the final baryon asymmetry is affected by the chosen mass ratios of the RH neutrinos. We find that the final \( Y_B \) is not particularly sensitive to \( M_2 \). A relook at (6.14) reminds us that the second term is suppressed compared to the first term, since the former is of the order of \( x_{12}^{-1} \). Thus, taking only the first term of (6.14) into consideration, the flavored CP asymmetry parameters of (6.12) can be simplified in terms of the rescaled parameters of (4.6) as

\[
\varepsilon_1^\mu = \frac{3 M_1}{8 \pi v^2} \left[ \frac{(x_1 x_2 + y_1 y_2 \cos \theta) y_1 y_2 \sin \theta}{x_1^2 + y_1^2} \right] = -\varepsilon_1^\tau. \tag{6.17}
\]
Since all rescaled parameters in (6.17) are fixed by the 3σ oscillation data, ε_{1\mu,\tau} are practically insensitive to the value of M_2. Nevertheless, for a precise numerical computation of the final baryon asymmetry, we need to take into account the effect of the second term in (6.14). The sensitivity of Y_B to the magnitude of the second term of (6.14) for different mass hierarchical schemes of the RH neutrinos will be discussed in detail in the numerical Section 7.

We now turn to discuss the direct effect of N_2. We have so far focused on the lepton asymmetry produced by the decay of the lightest of the heavy neutrinos. It is shown in Ref. [32] that, due to a decoherence effect, the amount of lepton asymmetry, generated by N_2 decays, gets protected against N_1-washout. The latter therefore survives down to the electroweak scale and contributes to the final baryon asymmetry. For this procedure to work out, two washout parameters Δ_1 = h_{11}M^{-1}_1m_*^{-1} and Δ_2 = h_{22}M^{-1}_2m_*^{-1} must satisfy the condition

\[ Δ_1 \gg 1 \] and \[ Δ_2 \gg 1 \] (6.18)

with \( m_* = 1.66\sqrt{g^*\pi v^2}/M_{Pl} \approx 10^{-3} \) eV. Here Δ_1 \( \gg 1 \) indicates that very fast N_1 interactions destroy the coherence among the states produced by N_2; hence a part of the lepton asymmetry produced by N_2 becomes blind to the N_1-washout and survives orthogonal to N_1-states. On the other hand, a mild washout of the lepton asymmetry, produced by N_2 due to N_2-related interactions, is represented by the Δ_2 \( \gg 1 \) condition. For such a mild washout scenario, a sizable lepton asymmetry generated by N_2 survives through the N_1-leptogenesis phase and hence contributes to the final baryon asymmetry. We shall elaborate on the validity of these conditions in our model in the following section.

7 Numerical analysis: methodology and discussion

In order to check the viability of our theoretical assumptions and consequent outcomes, we present a numerical analysis in substantial detail. Our method of analysis and organization are as follows. First, we utilize the 3σ values of the globally fitted neutrino oscillation data presented in Table 2 to constrain the parameter space in terms of the rescaled parameters defined in (4.6). For numerical computation, we make use of the exact analytical formulae for the light neutrino masses and mixing angles presented in Ref. [33]. It is seen that, in this complex extended \( \mu\tau \) antisymmetry scheme, an appreciable region of the parameter space could be well fitted within the 3σ range of the global oscillation data (see Fig.1) for each of the mass orderings.
We next discuss the predictions of the present model in the context of the $\beta\beta 0\nu$ experiments for both mass orderings. In order to estimate the value of $Y_B$, we make use of these constrained rescaled parameters with a subtlety. For the computation of $Y_B$ we need to evaluate the parameters of $m_D$ (i.e., $a_{1,2}$, $b_{1,2}$) and $M_i$ separately. Since we have only constrained the rescaled parameters, for a given set of rescaled parameters, there remains a freedom to make various sets of independent choices for the elements of $m_D$ along with $M_i$. Keeping this in mind, we explore two different numerical ways to discuss leptogenesis and its consequent outcomes. First, we choose a specific hierarchical mass spectrum for the RH neutrinos: $M_2/M_1 = 10^3$. Then, for a fixed value of $M_1$, we use the entire parameter space for the rescaled parameters to generate the elements of $m_D$ which are explicitly used to compute the final $Y_B$. This leads to a lower bound on $M_1$ below which $Y_B$ in the observed range cannot be generated. In another approach, instead of taking the entire rescaled parameter space, we focus only on that set of rescaled parameters which corresponds to a positive value of $Y_B$ (the sign of $Y_B$ depends upon

Figure 1: Rescaled parameter space for both the mass orderings. The plots in sky blue (deep blue) color represents the parameter space for normal (inverted) mass ordering.
the rescaled parameters) and observables that lie near their best-fit values. Then by varying $M_1$, we generate the corresponding parameters of $m_D$ using (4.6). Here we consider the same hierarchical scenario for the RH neutrinos as considered in the first approach. Now, for each value of $M_1$ and the corresponding parameters of $m_D$, we obtain a value for the final baryon asymmetry $Y_B$. Since $Y_B$ has an observed upper and a lower bound, we end up with an upper and a lower bound for $M_1$ also. Finally, we provide a numerical discussion regarding the effects of the heavy neutrino $N_2$ on the final $Y_B$ as explained analytically in the previous section. We next present the numerical results of our analysis in much more detailed and a systematic way.

Table 2: Input values fed into the analysis [14].

| Parameters                  | $\sin^2 \theta_{12}/10^{-1}$ | $\sin^2 \theta_{23}/10^{-1}$ | $\sin^2 \theta_{13}/10^{-2}$ | $\Delta m_{21}^2/10^{-5}$ (eV$^2$) | $|\Delta m_{31}^2|/10^{-3}$ (eV$^2$) |
|-----------------------------|-------------------------------|-------------------------------|-------------------------------|-----------------------------------|-----------------------------------|
| 3σ ranges (NO)             | 2.50 – 3.54                   | 3.81 – 6.15                   | 1.90 – 2.40                   | 6.93 – 7.96                       | 2.411 – 2.646                     |
| 3σ ranges (IO)             | 2.50 – 3.54                   | 3.83 – 6.36                   | 1.90 – 2.42                   | 6.93 – 7.96                       | 2.39 – 2.624                      |
| Best fit values (NO)       | 2.97                          | 4.25                          | 2.15                          | 7.37                             | 2.52                             |
| Best fit values (IO)       | 2.97                          | 5.89                          | 2.16                          | 7.37                             | 2.50                             |

As discussed in Sec.3, there are four sets of CP violating phases for the four independent $\tilde{d}$ matrices. Thus we get four different plots for each mass of the orderings of the light neutrinos. In Fig.2 we present the plots of $|M_{ee}|$ vs. the sum of the light neutrino masses ($\Sigma_i m_i$) for each mass ordering. Since the lightest neutrino mass is zero in each case, the other two masses ($m_2$ and $m_3$ for normal ordering and $m_2$ and $m_1$ for inverted ordering) get fixed in a very narrow range by the oscillation constraints on $\Delta m_{21}^2$ and $|\Delta m_{31}^2|$. It is evident from Fig.2 that $|M_{ee}|$ in each plot leads to an upper limit which is beyond the reach of the GERDA phase-II. However, predictions of our model could be probed by the combined GERDA + MAJORANA experiments [34]. The sensitivity reach of other promising experiments such as LEGEND-200 (40 meV), LEGEND-1K (17 meV) and nEXO (9 meV) [35] are also shown in Fig.2. For each case, the entire parameter space corresponding to an inverted neutrino mass ordering could be ruled out by the nEXO reach.

We now come to the numerical discussion of baryogenesis via flavored leptogenesis. As mentioned in the beginning of this section, we have performed the numerical computation pertaining to leptogenesis in two different ways. In one way, we have taken a particular value of $M_1$ and compute the final $Y_B$ for the entire rescaled parameter space constrained by the oscillation data. In the second way, we have used those values of the rescaled parameters for which the low energy neutrino observables predicted from our model lie close to their best fit
values dictated by the oscillation data in Table 2. To facilitate this purpose, we define a variable $\chi^2$ that measures the deviation of the parameters from their best fit values:

$$\chi^2 = \sum_{i=1}^{5} \left( \frac{O_i(th) - O_i(bf)}{\Delta O_i} \right)^2.$$  \hfill (7.1)

In (7.1) $O_i$ denotes the $i^{th}$ neutrino oscillation observable from among $\Delta m_{21}^2$, $\Delta m_{32}^2$, $\theta_{12}$, $\theta_{23}$ and $\theta_{13}$ and the summation runs over all such observables. The parenthetical $th$ stands for the numerical value of the observable predicted in our model, whereas $bf$ denotes the best fit value (cf. Table 2). $\Delta O_i$ in the denominator represents the measured 1$\sigma$ range of $O_i$. Primarily for numerical computation, we choose $M_2/M_1 = 10^3$. However, as indicated in the previous section, we also present a detailed discussion regarding the sensitivity of $Y_B$ to the chosen hierarchy of $M_i$. Next, we calculate $\chi^2$ as a function of the primed parameters for their entire constrained range. Then, for a fixed value of $M_1$, we choose that set of rescaled parameters which corresponds to the minimum value of $\chi^2$ and a positive value of $Y_B$. For that particular
\( \chi^2 \) and the corresponding set of rescaled parameters, we are then able to generate a large set of elements of \( m_D \) by varying \( M_1 \) over a wide range and can calculate \( Y_B \) for each value of \( M_1 \). An organized discussion is given in what follows.

**Computation of \( Y_B \) for a normal mass ordering of light neutrinos:**

\( M_1 < 10^9 \text{ GeV} \): In this regime, all three lepton flavors \((e, \mu, \tau)\) are distinguishable. Since \( \epsilon_1^e = 0 \), we need to individually evaluate \( \epsilon_1^{\mu, \tau} \) only. However, due to the imposed \( \mu\tau \) antisymmetry, two washout parameters \( \tilde{m}_\mu \) and \( \tilde{m}_\tau \) would be equal. Thus on account of the relation in (6.16), the final baryon asymmetry \( Y_B \) vanishes.

\( 10^9 \text{ GeV} < M_1 < 10^{12} \text{ GeV} \): For the evaluation of \( Y_B \) here, we have to look first at the washout parameters \( K_\tau \) and \( K_2 = K_\epsilon + K_\mu \). As shown in the first plot in the left panel of Fig.3, the entire allowed range of these parameters prefers to lie in \( K_\tau, K_2 > 1 \) region. Thus the efficiency factor in (6.6) can be written in a strong wash-out scenario [29] as

\[
\eta(\tilde{m}_\alpha) = \left( \frac{0.55 \times 10^{-3}}{\tilde{m}_\alpha} \right)^{1.16}, \tag{7.2}
\]

where \( \alpha = \tau, 2 \). As elaborated in the previous section, the assumed strong hierarchy of RH neutrinos makes the second RHS term in (6.14) much smaller than the first term. Hence the final CP asymmetry could be simplified to the form as in (6.17) so that the final \( Y_B \) in (6.15) is practically proportional to the free parameter \( M_1 \). Now for a fixed value of \( M_1 \), we compute \( Y_B \) for the entire rescaled parameter space. In Fig.3, the variation of \( Y_B \) with the rescaled parameters is shown for a representative value of \( M_1 = 10^{11} \text{ GeV} \). Any further lowering of the value of \( M_1 \) would cause these plots (except the first plot in the left panel) to condense along \( Y_B \) axis due to the addressed proportionality of \( Y_B \) with \( M_1 \). Thus, below a certain value of \( M_1 \), one would end up with a value for \( Y_B \) which is below the lower end \( 8.55 \times 10^{-11} \) of the observed range for the latter. We find this lower bound on \( M_1 \) to be \( 6.21 \times 10^{10} \text{ GeV} \) for which the peak of a \( Y_B \) vs \( \theta, x_{1,2}, y_{1,2} \) curve in Fig.3 just touches the red stripe that represents the experimental observed range of \( Y_B \).

Next, we concentrate on the other way which is a search for a set of rescaled parameters that corresponds to the low energy neutrino observables close to their best fit values and hence the minimum value of \( \chi^2 \). For this purpose, we take a particular set from the rescaled parameter space, calculate the corresponding \( \chi^2 \) using (7.1) and then compute \( Y_B \). We have found that \( \chi^2_{\text{min}} \) should be 0.397 for \( Y_B \) to be positive. A complete data set of the rescaled parameters and corresponding values of the observables are tabulated in Table 3 for \( \chi^2_{\text{min}} = 0.397 \).
Figure 3: The first figure the left panel shows the ranges for the washout parameters. Rest of the plots represent the variation of $Y_B$ with the rescaled parameters for a representative value $M_1 = 10^{11}$ GeV.
Table 3: Parameters and observables corresponding $\chi^2 = 0.397$ for normal mass ordering.

| $x_1$ | $x_2$ | $y_1$ | $y_2$ | $\theta$ | $\chi^2_{\text{min}}$ |
|-------|-------|-------|-------|----------|----------------|
| -0.040 | -0.014 | -0.01 | 0.155 | 114° | 0.397 |

| observables | $\theta_{13}$ | $\theta_{12}$ | $\Delta m^2_{21} \times 10^5$ | $|\Delta m_{31}|^2 \times 10^3$ |
|-------------|-------------|-------------|----------------|----------------|
| $\chi^2_{\text{min}} = 0.397$ | 8.42° | 33.04° | 7.47 (eV)$^2$ | 2.55 (eV)$^2$ |

Given the rescaled data set for the $\chi^2_{\text{min}}$, $M_1$ is varied widely to secure $Y_B$ in the observed range. For each value of $M_1$, a set of values of the parameters in the elements of $m_D$ is generated. The final $Y_B$ is then calculated for each value of $M_1$ and the corresponding parameters of $m_D$. A careful surveillance of the plot in Fig.4 leads to the conclusion that we can obtain an upper and a lower bound on $M_1$ corresponding to the observed constraint on $Y_B$. In order to realize this fact more clearly, two straight lines have been drawn parallel to the abscissa in the mentioned plot: one at $Y_B = 8.55 \times 10^{-11}$ and the other at $Y_B = 8.77 \times 10^{-11}$. The values of $M_1$, where the straight lines connect the $Y_B$ vs $M_1$ curve, yield the allowed upper and lower bounds on $M_1$, namely $(M_1)_{\text{upper}} = 7.35 \times 10^{10}$ GeV and $(M_1)_{\text{lower}} = 7.19 \times 10^{10}$ GeV. Again, the near linearity of the $Y_B$ vs. $M_1$ curve in Fig.4 follows from the previously explained approximate proportionality of $Y_B$ with $M_1$. One might also ask about the narrow range for $M_1$ as observed in Fig.4. Note that in this plot we have presented our result for a particular set of rescaled parameters (with $\chi^2_{\text{min}} = 0.397$). In principle, one could take the entire rescaled parameter space of our model and compute the corresponding results on $Y_B$ and $M_1$ for each set of the mentioned parameters. In that case the range of $M_1$ would not be as narrow as shown in Fig.4.

Figure 4: $Y_B$ vs. $M_1$ curve corresponding to $\chi^2_{\text{min}} = 0.397$ for a normal mass ordering of the light neutrinos
**M_1 > 10^{12} \text{ GeV:**} In this regime Y_B is zero since the flavored sum CP asymmetry parameter \( \sum_\alpha \epsilon_1^\alpha \) vanishes. Obviously, Y_B might be generated in this regime also if one consider small breaking of CP symmetry in the neutrino sector as discussed in Ref. [36].

**Computation of Y_B for an inverted mass ordering of light neutrinos:**

In this case also the observed range of Y_B cannot be generated for \( M_1 < 10^9 \text{ GeV} \) and \( M_1 > 10^{12} \text{ GeV} \) owing to reasons similar to those explained in the case of a normal ordering. However, we find that in the case of an inverted ordering, Y_B cannot be generated in the observed range even if we consider a \( \tau \)–flavored regime, i.e., \( 10^9 \text{ GeV} < M_1 < 10^{12} \text{ GeV} \). Numerically, for a value \( M_1 = 9.9 \times 10^{11} \text{ GeV} \), Y_B is computed to be \( Y_B = 8.20 \times 10^{-11} \). Thus from a hierarchical leptogenesis perspective, an inverted mass ordering is disfavored in our model with a complex (CP) extended antisymmetry.

**The effect of N_2 on Y_B**

As mentioned in the previous section, there are two different ways in which the heavy RH neutrino N_2 might affect the final value of Y_B. In the first, which we name as the indirect effect, the final Y_B becomes practically insensitive to the mass of N_2 since the second term is suppressed compared to the first term in (6.14). Now \( \epsilon_1^\mu \) can be written in a simpler form which is independent of \( M_2 \). c.f. (6.17); hence it does not depend the mass ratio \( M_2/M_1 \). However, for a precise computation of Y_B, we need to consider the term neglected in (6.14); that in turn motivates us to perform a quick check of the RH neutrino mass hierarchy sensitivity of the produced value of Y_B. For this purpose, in addition to the standard hierarchical case, i.e. \( M_2/M_1 = 10^3 \), we calculate Y_B for two other different mass hierarchical schemes, \( M_2/M_1 = 10^2 \) and \( M_2/M_2 = 10^4 \). From Fig.5 we can infer that though the chosen mass ratios of the RH neutrinos are altered, changes in the lower and upper bounds on M_1 are practically insignificant. For the allowed normal light neutrino mass ordering, the variation of Y_B with M_1 for different mass ratios of the RH neutrinos has been presented in Table 4.

**Table 4: Lower and upper bounds on M_1 for different mass ratios of the RH neutrinos.**

| Case-I: Normal light neutrino ordering | M_2/M_1 = 10^2 | M_2/M_1 = 10^3 | M_2/M_1 = 10^4 |
|---------------------------------------|----------------|----------------|----------------|
| Hierarchies \( \rightarrow \)         |                |                |                |
| Upper bound (GeV)                     | 7.32 \times 10^{10} | 7.35 \times 10^{10} | 7.38 \times 10^{10} |
| Lower bound (GeV)                     | 7.16 \times 10^{10} | 7.19 \times 10^{10} | 7.20 \times 10^{10} |

It is obvious from the entries of Table 4 that a slight difference in the upper and lower bounds on M_1 in a particular column, as compared to the other column, arises due the depen-
dence of $M_2$ on the second term in (6.14). For a fixed value of $M_1$, the contribution from the second term in (6.14) is larger for $M_2/M_1 = 10^2$ and smaller for $M_2/M_1 = 10^4$, as compared to the standard $M_2/M_1 = 10^3$ case. Hence for $M_2/M_1 = 10^2$, the slope of the $Y_B$ vs. $M_1$ curve is larger than for $M_2/M_1 = 10^3$. Consequently, for the allowed range of $Y_B$, both the upper and the lower bounds get slightly left shifted on the $M_1$-axis (compared to the standard $M_2/M_1 = 10^3$ case). Proceeding in the same way, we obtain somewhat right shifted bounds for $M_2/M_1 = 10^4$ case.

Figure 5: $Y_B$ vs. $M_1$ plots corresponding to $\chi^2_{\text{min}} = 0.397$ for the normal mass ordering of the light neutrinos. The plot in the left is for $M_2/M_1 = 10^2$ and the plot in the right is for $M_2/M_1 = 10^4$.

In contrast, in the direct effect, any asymmetry produced by $N_2$ survives provided the conditions $\Delta_1 \gg 1$ and $\Delta_2 \gg 1$, cf. (6.18), are satisfied. From Fig.6 we observe that the

Figure 6: washout parameters for $N_2$ leptogenesis

allowed parametric region prefers large values of $\Delta_2$ in excess of 10 except at the bottom
Thus the condition $\Delta_2 \gg 1$ is violated in most of the region. Moreover the $\chi^2_{min} = 0.397$, for which we calculate final $Y_B$ strongly violates $\Delta_2 \gg 1$ condition. A tiny amount of parameter space with $\Delta_2 < 10$ corresponds to values of $\chi^2$ above 0.9 which is much higher than $\chi^2_{min}$ for which we compute $Y_B$ in the observed range. Therefore, in our final result, any direct effect of $N_2$ is not significant. Note that there is nothing special about $\chi^2 = 0.9$. The issue we are trying to address here, is that there are indeed some data points in the model parameter space for which the conditions for $N_2$ leptogenesis could be satisfied. However, the minimum value of $\chi^2$ for those data sets is 0.9. This means that the corresponding observables are away from their best-fit values (though well within 1\(\sigma\)) and thus the obtained bounds on $M_1$ (e.g. Fig.4) will not be affected by $N_2$ leptogenesis. However, if one goes beyond $\chi^2 \approx 0.9$, the asymmetry produced by $N_2$ could play a crucial role.

We would like to conclude this section by comparing our results on leptogenesis with those obtained earlier in previous literature in case of a $\mu \tau$ flavored CP symmetry. Existing references such as [12,19,36] also discuss leptogenesis within the framework of residual CP symmetry (in particular CP$^{\mu \tau}$) and point out the nonoccurrence of unflavored leptogenesis and only the viability of the $\tau$–flavored scenario similar to our proposal of a exact $\mu \tau$ antisymmetry in the neutrino sector. However, the final numerical analysis is different from our case. In particular, all the mentioned references mainly focus on the three neutrino case where one cannot fix the Yukawa couplings only with the oscillation data. Thus any final result on leptogenesis requires other assumptions to constrain all the Yukawas. We focus on the two RH neutrino case, namely the minimal seesaw mechanism, where the entire Yukawa parameter (rescaled by RH neutrino masses) space could be constrained by the neutrino oscillation data. Hence all the results obtained, in particular for the RH neutrino masses, are exactly dictated by the oscillation data. For a hierarchical RH mass spectrum, Ref. [19] shows a variation of $Y_B$ with a single model parameter for a fixed value of $M_1$ and best-fit values of the oscillation parameters. However, here we focus on the bounds on $M_1$ for the entire parameter space as well as the for the parameter set that corresponds to the observables which lie near to their best-fit values. For the first case, we obtain a lower bound on $M_1$ while in the other, we obtain an upper as well as a lower bound on $M_1$. In addition, we have done a thorough study of the RH neutrino hierarchy sensitivity of the final $Y_B$ and showed the possible changes in the bounds on the lightest RH neutrino $M_1$ for three different RH neutrino hierarchical mass spectra. We have also showed that, for this minimal seesaw with a complex $\mu \tau$ antisymmetry, the inverted mass ordering is not a viable option as far as hierarchical leptogenesis is concerned. We are not within the framework of a Grand Unified Theory (GUT) such as SO(10), where the lepton asymmetry generated by the next to light RH neutrino ($N_2$), is a natural requirement to produce correct value of $Y_B$ [37, 38]. Nevertheless, we opt for fast $N_1$ interactions which are responsible for the survival of the lepton asymmetry generated by $N_2$ [32]. For this CP symmetric framework we have showed for the first time that there could be a parameter space...
left for which $N_2$ leptogenesis might affect the final value of $Y_B$ (though a rigorous study of the $N_2$ leptogenesis is beyond the scope of this paper). Ref. [12] concluded that for the mass regime $M_1 < 10^9 \text{GeV}$, a resonant leptogenesis is only possible if one considers breaking in $CP^{\mu\tau}$, since in this regime the muon and tauon washout parameters are of equal strength. In our proposal of $CP^{\mu\tau A}$ also, this conclusion is true. However, as we show in the appendix, unlike the hierarchical RH neutrino mass spectrum, RH neutrinos with a mild hierarchy could also result in a successful leptogenesis for $M_1 \approx 10^9 \text{GeV}$. We showed that an inverted mass ordering could then be a viable option for a successful leptogenesis. We also comment on the strength of the mild hierarchy by solving numerically the formulae for $Y_B$ within the framework of flavor diagonal RH neutrinos. In our analysis, the sign of $Y_B$ depends upon the Yukawa parameters. In this context we refer to [36] which shows how, within the framework of a CP symmetry, the sign of $Y_B$ depends upon the observables.

8 Concluding comments and discussion

In this paper the complex (CP) extension of $\mu\tau$ antisymmetry has been shown to yield a $M_{CP^{\mu\tau A}}$ which is simply related to $M_{CP^{\mu\tau}}$ - the Majorana mass matrix from the complex (CP) extension of $\mu\tau$ symmetry with both having identical phenomenological consequences. These phenomenological consequences of $CP^{\mu\tau A}$ have been worked out within a minimal seesaw scheme with two strongly or mildly hierarchical RH neutrinos $N_1$ and $N_2$. We have further investigated baryogenesis via leptogenesis in this scenario and derived upper and lower bounds on the mass of $N_1$.

To summarize, we have proposed a new idea, namely a complex extended $\mu\tau$ antisymmetry, pertaining to the neutrino sector and have worked out its consequences. Unlike the real $\mu\tau$ antisymmetry, we envisage there is no need for any breaking of it in the neutrino sector. Atmospheric neutrino mixing is predicted to be maximal ($\theta_{23} = \pi/4$) in this scheme while the solar and reactor mixing angles ($\theta_{12}$ and $\theta_{13}$ respectively) can be fit to their observed values. Neutrino masses get generated via the minimal seesaw mechanism with two heavy right-chiral neutrinos. The lightest neutrino is predicted to be massless while the two other neutrino masses can be fit to the observed range of values of $|\Delta m^2_{32}|$ and $\Delta m^2_{12}$ both for a normal and an inverted mass ordering. Concrete predictions are made for neutrinoless double beta decay: the ongoing experiments are not expected to observe it though the planned nEXO experiment may have a chance to do so. Finally, we have made a detailed quantitative examination of baryogenesis via leptogenesis in our scheme including the indirect and direct effects of the heavier RH neutrino $N_2$. $\tau$-flavored leptogenesis with a normal mass ordering turns out to be the only viable possibility that can generate $Y_B$ in the observed range in a hierarchical leptogenesis scenario.
A Discussion of the case with mildly hierarchical RH neutrinos

In the text we have dealt with a strongly hierarchical RH neutrino mass spectrum and found only the $\tau$-flavored regime to be viable in producing the correct $Y_B$ for a normal light neutrino mass ordering. Since in our chosen basis [19], RH neutrinos are nondegenerate, it would also be interesting to study leptogenesis with a mildly hierarchical including a quasidegenerate $N_R$ mass spectrum. We will see later in this discussion that RH neutrinos which are not strongly hierarchical might obliterate all the new bounds on $M_1$ that we obtained earlier.

In general, a quasidegenerate RH neutrino mass spectrum is considered for studying leptogenesis in a low energy seesaw scenario (resonant leptogenesis [27]); here the RH neutrinos could have masses $\mathcal{O}(\text{TeV})$. However, in our analysis, we cannot lower the RH neutrino masses below $10^9$ GeV, since that would correspond to the fully flavored regime where the two washout parameters $\tilde{m}_\mu$ and $\tilde{m}_\tau$ are the same due to the imposed $\mu\tau$ antisymmetry, thereby implying a vanishing $Y_B$ cf.(6.16). However, depending on the chosen mild mass splitting of the RH neutrinos, we can lower the lightest RH neutrino mass down to $10^9$ GeV below which the muon charged lepton flavor equilibrates. In scenarios where the RH neutrinos are not strongly hierarchical, instead of (6.3), it is useful to use the general formula for the CP asymmetry parameter [27] $\varepsilon_i^\alpha$ as

$$
\varepsilon_i^\alpha = \frac{1}{4\pi v^2 h_{ii}} \sum_{j \neq i} \text{Im}\{h_{ij}(m_D)_{i\alpha}(m^*_D)_{j\alpha}\} \left[ f(x_{ij}) + \frac{\sqrt{x_{ij}(1-x_{ij})}}{(1-x_{ij})^2 + h_{jj}^2(16\pi^2 v^4)^{-1}} \right]
+ \frac{1}{4\pi v^2 h_{ii}} \sum_{j \neq i} \frac{(1-x_{ij})\text{Im}\{h_{ji}(m_D)_{i\alpha}(m^*_D)_{j\alpha}\}}{(1-x_{ij})^2 + h_{jj}^2(16\pi^2 v^4)^{-1}}. \quad (A.1)
$$

Note that, unlike (6.3) the above equation is valid for degenerate RH neutrinos also.

Taking into account the contribution from both the RH neutrinos, we have performed a numerical study to find the final $Y_B$ for the lowest allowed value of $M_1 (= 10^9\text{GeV})$. It turns out that for a normal light neutrino mass ordering, $M_2$ could at most be $\approx 17.5M_1$ to produce the observed lower bound $8.55 \times 10^{-11}$ of $Y_B$ cf.(6.1). One can see that the obtained mass spectrum is fairly hierarchical though the hierarchy is not very strong. Of course any number smaller than 17.5 would result in an enhancement of the produced CP asymmetry. Thus the observed range of $Y_B$ could be generated with a quasidegenerate RH mass spectrum too. Interestingly, an inverted light neutrino mass ordering which is disfavoured for a strongly hierarchical RH neutrino mass spectrum is now a perfectly viable scenario since we relax the strong hierarchy assumption. Again, as in the previous case, i.e., for $M_1 = 10^9\text{GeV}$, it is numerically found...
that one needs $M_2 \leq 1.8M_1$ in order to produce the observed lower bound on $Y_B$. Note that, unlike in the case of a normal light neutrino mass ordering, the RH neutrino mass spectrum here favours a **mild hierarchical scenario** as we lower the value of $M_1$. We could also point out that here we have considered the flavor diagonal RH neutrinos to calculate the asymmetry. Nevertheless, for a resonant leptogenesis scenario, a full flavor-covariant treatment might play an important role [30].

As a concluding remark, we may mention once again that, owing to the imposed symmetry, a fully flavored leptogenesis is not possible for $M_1 < 10^9$ GeV even if we consider strongly degenerate RH neutrinos. Nevertheless, a small breaking of the symmetry [36], or somewhat a more moderate version of the symmetry such as the scaling ansatz [15] will cause a deviation from $\tilde{m}_\mu = \tilde{m}_\tau$ cf. (6.16) and will imply a nonvanishing $Y_B$. In such cases leptogenesis with heavily degenerate RH neutrinos (resonant leptogenesis) could be an interesting topic to study.
