ON THE RATE OF CONVERGENCE OF SIMPLE AND JUMP-ADAPTED WEAK EULER SCHEMES FOR LÉVY DRIVEN SDES

R. MIKULEVICIUS

Abstract. The paper studies the rate of convergence of a weak Euler approximation for solutions to possibly completely degenerate SDEs driven by Lévy processes, with Hölder-continuous coefficients. It investigates the dependence of the rate on the regularity of coefficients and driving processes and its robustness to the approximation of the increments of the driving process. A convergence rate is derived for some approximate jump-adapted Euler scheme as well.

1. Introduction

The paper studies the weak Euler approximation for solutions to possibly completely degenerate SDEs driven by Lévy processes. As in [12], the main goal is to investigate the dependence of the convergence rate on the regularity of coefficients and driving processes. In addition, we consider the robustness of the results to the approximation of the law of the increments of the driving noise in the whole scale of time discretization errors.

Let \((\Omega, \mathcal{F}, \mathbb{P})\) be a complete probability space with a filtration \(\mathcal{F} = \{\mathcal{F}_t\}_{t \in [0, T]}\) of \(\sigma\)-algebras satisfying the usual conditions and \(\alpha \in (0, 2]\) be fixed. Consider the following model in \(\mathbb{R}^d\):

\[
X_t = X_0 + \int_0^t a(X_s)ds + \int_0^t b(X_s)dW_s + \int_0^t G(X_{s-})dZ_s, t \in [0, T],
\]

where \(a(x) = (a^i(x))_{1 \leq i \leq d}, b(x) = (b^j(x))_{1 \leq i \leq d, 1 \leq j \leq n}, G(x) = (G^{ij}(x))_{1 \leq i \leq d, 1 \leq j \leq m}\), \(x \in \mathbb{R}^d\) are measurable and bounded, with \(a = 0\) if \(\alpha \in (0, 1)\) and \(b = 0\) if \(\alpha \in (0, 2)\). The process \(W_s\) is a standard Wiener in \(\mathbb{R}^n\). The last term is driven by \(Z = \{Z_t\}_{t \in [0, T]}\), an \(m\)-dimensional Lévy process whose characteristic function is \(\exp \{t\eta(\xi)\}\) with

\[
\eta(\xi) = \int_{\mathbb{R}^m} \left[ e^{i\langle \xi, v \rangle} - 1 - i\chi_\alpha(v)(\xi, v) \right] \pi(dv),
\]

\(\sqrt{\mathbb{E}_{\mathcal{F}_t} |\xi|^2} \leq C \sqrt{\mathbb{E}_{\mathcal{F}_t} |\xi|^2}
\]

Key words and phrases. Parabolic integro-differential equations, Weak Euler scheme, Approximate and jump-adapted Euler schemes.
where $\chi_\alpha(v) = \chi_{\{|v|\leq 1\}}^1 \{\alpha \in (1,2]\}$. Hence,

$$Z_t = \int_0^t \int \left(1 - \chi_\alpha(v)\right)up(ds,dv) + \int_0^t \int \chi_\alpha(v) vq(ds,dv),$$

where $p(dt,dv)$ is a Poisson point measure on $[0,\infty) \times R_0^m$ ($R_0^m = R^m \setminus \{0\}$) with $E[p(dt,dv)] = \pi(dv)dt$, and $q(dt,dv) = p(dt,dv) - \pi(dv)dt$ is the centered Poisson measure. It is assumed that $Z_t$ is a Lévy process of order $\alpha$:

$$\int (|v|^\alpha \wedge 1) \pi(dv) < \infty.$$

Let the time discretization $\{\tau_i, i = 0, \ldots, n\}$ of the interval $[0,T]$ with maximum step size $\delta > 0$ be a partition of $[0,T]$ such that $0 = \tau_0 < \tau_1 < \cdots < \tau_{n_T} = T$ and $\max_i(\tau_i - \tau_{i-1}) \leq \delta$. The Euler approximation of $X$ is an $F$-adapted stochastic process $Y = \{Y_t\}_{t \in [0,T]}$ defined by the stochastic equation

$$(1.2) \quad Y_t = X_0 + \int_0^t a(Y_{\tau_i}) ds + \int_0^t b(Y_{\tau_i}) dW_s + \int_0^t G(Y_{\tau_i}) dZ_s, t \in [0,T],$$

where $\tau_i = \tau_i$ if $s \in [\tau_i, \tau_{i+1})$, $i = 0, \ldots, n_T - 1$. Contrary to those in (1.1), the coefficients in (1.2) are piecewise constants in each time interval of $[\tau_i, \tau_{i+1})$.

The weak Euler approximation $Y$ is said to converge with order $\kappa > 0$ if for each bounded smooth function $g$ with bounded derivatives, there exists a constant $C$, depending only on $g$, such that

$$|Eg(Y_T) - Eg(X_T)| \leq C\delta^\kappa,$$

where $\delta > 0$ is the maximum step size of the time discretization.

The weak Euler approximation of stochastic differential equations with smooth coefficients and $G = 0$ has been consistently studied. For diffusion processes, Milstein was one of the first to investigate the order of weak convergence and derived $\kappa = 1$ [13, 14]. Talay considered a class of the second order approximations for diffusion processes [15, 19]. For Itô processes with jump components (a finite number of jumps in a finite interval), it was shown in [9] the first-order convergence in the case in which the coefficient functions possess fourth-order continuous derivatives. Platen and Kloeden & Platen studied not only Euler but also higher order approximations [5, 15] and references therein.

Protter & Talay ([17]) analyzed the weak Euler approximation for (1.1) with $\alpha = 2$. They proved that the order of convergence is $\kappa = 1$, provided that $G, b, a$ and $g$ have four bounded derivatives and the Lévy measure of $Z$ has finite moments of the order $\mu = 8$. In this paper we show that $\kappa = 1$ can be achieved when $\mu = 4$ and there still is some order of convergence for $\mu \in (2, 4]$. Moreover, we assume $\beta$-Lipschitz continuity of the coefficients and $g$ and derive that for $\alpha < \beta \leq \mu \leq 2\alpha$ the order of convergence $\kappa = \frac{2}{\alpha} - 1$. In
particular, when $\beta = \mu = 2\alpha$ with $\alpha \in (0, 2)$ (the diffusion part is absent), the convergence order is still $\kappa = 1$.

As in [10] and [12], this paper employs the idea of Talay (see [18]) and uses the solution to the backward Kolmogorov equation associated with $X_t$, Itô's formula, and one-step estimates. Since one step estimates were derived in [12], the main difficulty is to solve the degenerate backward Kolmogorov equation in Lipschitz classes (see Theorem 4 below). We obtain the solution of the degenerate equation as a limit of solutions to regularized (nondegenerate) equations. Although the solution to (1.1) is strong and probabilistic arguments are applied for the uniform Lipshitz estimates of the approximating sequence, contrary to [17], we do not use derivatives of the stochastic flows.

If (1.1) has a nondegenerate main part, some assumptions imposed can be relaxed (see [12], [10], Kubilius & Platen and Platen & Bruti-Liberati [8, 16]). More complex and higher order schemes were studied and discussed, for example, by Cont and Tankov, Jourdain and Kohatsu-Higa (see [1], [4] and references therein).

Motivated by the difficulty to approximate the increments of the driving processes, Jacod, Kurtz, Méléard and Protter in [3], studied the approximated Euler scheme where the increments of $Z$ are substituted by i.i.d. random variables that are easier to simulate. There are two sources of errors in this case. One comes from time discretization and the other one from substitution. We extend some of the results in [3] to the whole rate scale and show that the errors add up. In particular, the driving process $Z$ can be replaced with a Levy process $\tilde{Z}$ having finite number of jumps in $[0, T]$ by possibly cutting small jumps of $Z$ and sometimes replacing them with a Wiener process or drift. In addition, we consider a simple jump-adapted Euler scheme and show that presence of $\tilde{Z}$-jump moments in the partition $\{\tau_i\}$ influences the convergence rate. The approximation itself is simpler and assumptions imposed are different than those introduced by Kohatsu-Higa and Tankov in [15] (see references therein as well) for a more sophisticated (higher order) jump-adapted scheme.

The paper is organized as follows. In Section 2, some notation is introduced, the main results stated and the proof of the main theorem is outlined. In Section 3, we present the essential technical results about backward degenerate Kolmogorov equation, followed by the proof of the main theorem in Section 4. The robustness of the approximation and jump-adapted Euler scheme is considered as well. In the last section we discuss the optimality of the imposed assumptions.

2. Notation and Main Result

Denote $H = [0, T] \times \mathbb{R}^d$, $\mathbb{N} = \{0, 1, 2, \ldots\}$, $\mathbb{R}_0^d = \mathbb{R}^d \setminus \{0\}$. For $x, y \in \mathbb{R}^d$, write $(x, y) = \sum_{i=1}^d x_i y_i$. For $(t, x) \in H$, multiindex $\gamma \in \mathbb{N}^d$ with $D^\gamma =$
where \( \pi \) is the Lévy measure of the driving process \( X \).

Then there is a constant \( C \) such that for all \( g \in \tilde{C}^\beta (\mathbb{R}^d) \)

\[
|\mathbf{E}g(Y_T) - \mathbf{E}g(X_T)| \leq C|g|_\beta \delta^{d-1}.
\]

Applying Theorem 1 to the case \( \alpha = 2 \) we have an obvious consequence in the jump-diffusion case.

**Corollary 1.** Consider the jump-diffusion case \( (\alpha = 2) \)

\[
X_t = X_0 + \int_0^t a(X_s) ds + \int_0^t b(X_s) dW_s + \int_0^t G(X_{s-}) dZ_s, \ t \in [0, T].
\]
Let $2 < \beta \leq \mu \leq 4$. Assume $a, b^j, G^{ij} \in \bar{C}^\beta (\mathbb{R}^d)$ and

$$\int_{|v| \leq 1} |v|^2 \pi (dv) + \int_{|v| > 1} |v|^\mu \pi (dv) < \infty.$$ 

Then there is a constant $C$ such that for all $g \in \bar{C}^\beta (\mathbb{R}^d)$

$$|E g(Y_T) - E g(X_T)| \leq C|g|_\beta \delta^{2/\beta}.$$ 

An immediate extension of Theorem 1 (for the test function $g \in \bar{C}^\alpha (\mathbb{R}^d)$ with $\nu \in (0, \beta]$, the following statement.

**Corollary 2.** Let $\alpha < \beta \leq \mu \leq 2\alpha$, and assume $a^i, b^{ij} \in \bar{C}^\beta (\mathbb{R}^d), G^{ij} \in \bar{C}^\beta (\mathbb{R}^d)$, and

$$\int_{|v| \leq 1} |v|^\alpha d\pi + \int_{|v| > 1} |v|^\mu \pi (dv) < \infty,$$

where $\pi$ is the Lévy measure of the driving process $Z$. Let $\nu \in (0, \beta]$. Then there is a constant $C$ such that for all $g \in \bar{C}^\nu (\mathbb{R}^d)$

$$|E g(Y_T) - E g(X_T)| \leq C|g|_\nu \delta^{(\frac{1}{\alpha} - \frac{1}{\beta})}.$$ 

**Remark 1.** In particular, if $\alpha \in [1, 2], \mu = \beta = 2\alpha$ and $g$ is Lipshitz ($\nu = 1$), then the convergence rate $\kappa = \frac{1}{2\alpha}$.

2.1. **Approximate simple Euler scheme.** Following [3], for $\sigma \in (0, 1), \delta > 0$, we choose a time discretization $\{\tau_i\}$ and replace the increments of the driving process $Z_{\tau_{i+1}} - Z_{\tau_i}$ in [1, 2] by $F_{\tau_i}$-conditionally independent random variables $\zeta_i, i = 0, \ldots, n_T - 1$. We assume that there is a function $\phi(\sigma)$ such that $\lim_{\sigma \to 0} \phi(\sigma) = 0$ and for $i = 0, \ldots, n_T - 1$,

$$|\mathbb{E} [h (Z_{\tau_{i+1}} - Z_{\tau_i}) - h (\zeta_{i+1}) | F_{\tau_i}]| \leq C|h|_\beta \phi (\sigma)(\tau_{i+1} - \tau_i), h \in \bar{C}^\beta (\mathbb{R}^d).\tag{2.1}$$

with some constant $C$, independent of $\sigma, \delta$ and $h$. Let $\xi_t = 0$ if $0 \leq t < \tau_1, \xi_t = \zeta_i$ if $t_i \leq t < t_{i+1}, i = 1, \ldots, n_T - 1$. We still assume that $\max (\tau_{i+1} - \tau_i) \leq \delta$ and approximate $X_t$ by

$$\tilde{Y}_t = X_0 + \int_0^t a(\tilde{Y}_{\tau_i}) ds + \int_0^t b(\tilde{Y}_{\tau_i}) dW_s + \int_0^t G(\tilde{Y}_{\tau_i}) d\xi_s, t \in [0, T].\tag{2.2}$$

In this case $\tilde{Y}_t$ depends on $\delta$ and $\sigma$.

In the following example we approximate the increments of $Z_t$ by the increments of a Lévy process with finite number of jumps in $[0, T]$. This approximation is constructed by cutting small jumps of $Z_t$. We replace the small jumps part by appropriately chosen drift if $\alpha < \beta \in (1, 2], \alpha \in (0, 1]$. If $\alpha < \beta \in (2, 3], \alpha \in (1, 2]$, the small jumps part is replaced by a Wiener process. Given $\sigma \in (0, 1)$, we denote $B^\sigma$ the square root of the positive definite $m \times m$-matrix $(\int_{|v| \leq \sigma} v_i v_j d\pi)_{1 \leq i, j \leq m}$. Let $\tilde{W}_t$ be a standard independent Wiener process in $\mathbb{R}^m$. 

**CONVERGENCE RATE OF WEAK EULER SCHEMES**

5
Example 1. For \( \sigma \in (0, 1) \) we approximate

\[
Z_t = \int_0^t \int (1 - \chi_\alpha(v))v^p(ds, dv) + \int_0^t \int \chi_\alpha(v)v^q(ds, dv), t \in [0, T],
\]

by

\[
\tilde{Z}_t = Z_t^\sigma + \tilde{R}_t^\sigma,
\]

with

\[
Z_t^\sigma = \int_0^t \int |v| > \sigma (1 - \chi_\alpha(v))v^p(ds, dv) + \int_0^t \int |v| > \sigma \chi_\alpha(v)v^q(ds, dv)
\]

and

\[
\tilde{R}_t^\sigma = \begin{cases} 
  t \int_{|v| \leq \sigma} v^\pi(dv) & \text{if } \alpha < \beta \in (1, 2], \alpha \in (0, 1], \\
  B^\sigma \tilde{W}_t & \text{if } \alpha < \beta \in (2, 4], \alpha \in (1, 2], \\
  0 & \text{otherwise}.
\end{cases}
\]

In this case (see Lemma 6 below) (2.1) holds with

\[
\phi(\sigma) = \int_{|v| \leq \sigma} |v|^{\beta/3}d\pi
\]

and

\[
(2.3) \quad \zeta_{i+1} = \tilde{Z}_{\tau_{i+1}} - \tilde{Z}_{\tau_i}, i = 0, \ldots, n_T - 1.
\]

We show that time discretization and substitution errors add up.

Theorem 2. Let \( \alpha < \beta \leq \mu \leq 2\alpha \), and let \( a^i, b^{ij} \in \tilde{C}^\beta(R^d) \), \( C^{ij} \in \tilde{C}^{\beta \vee 1}(R^d) \), and

\[
\int_{|v| \leq 1} |v|^\alpha d\pi + \int_{|v| \geq 1} |v|^\mu \pi(dv) < \infty,
\]

where \( \pi \) is the Lévy measure of the driving process \( Z \). Assume that there is a function \( \phi(\sigma) \) such that \( \lim_{\sigma \to 0} \phi(\sigma) = 0 \) and for \( i = 0, \ldots, n_T - 1 \),

\[
(2.4) \quad |Eh(Z_{\tau_{i+1}} - Z_{\tau_i}) - Eh(\zeta_{i+1})| \leq C|h|_3\phi(\sigma)(\tau_{i+1} - \tau_i), h \in \tilde{C}^\beta(R^d),
\]

for some constant \( C \).

Then there is a constant \( C \) (independent of \( \sigma, \delta \)) such that for all \( g \in \tilde{C}^\beta(R^d) \)

\[
|Eg(\tilde{Y}_T) - Eg(X_T)| \leq C|g|_\beta \delta^\beta + \phi(\sigma).
\]

The same way as Corollary 2 (see the proof below) we have the following statement.

Corollary 3. Let assumptions of Theorem 2 hold and \( \nu \in (0, \beta] \). Then there is a constant \( C \) such that for all \( g \in \tilde{C}^\nu(R^d) \)

\[
|Eg(\tilde{Y}_T) - Eg(X_T)| \leq C|g|_\nu \delta^{\nu(\frac{1}{\beta} - \frac{1}{\nu})} + \phi(\sigma)^{\frac{\nu}{\beta}}.
\]
Remark 2. (i) Assume the assumptions of Theorem 2 hold. Since \( \lim_{\sigma \to 0} \phi(\sigma) = 0 \), for each \( \delta > 0 \) there is \( \sigma = \sigma(\delta) \) such that \( \phi(\sigma(\delta)) \leq \delta^{\frac{2}{\alpha} - 1} \) and therefore

\[
|Eg(\tilde{Y}_T) - Eg(X_T)| \leq C|g|_\beta \delta^{\frac{2}{\alpha} - 1}.
\]

In particular, if \( \phi(\sigma) \leq C\sigma^{\mu} \) with \( \mu > 0 \) (it is the case in Example 1 for a small jumps \( \alpha' \)-stable-like driving process \( Z \) with \( \alpha' < \alpha \)), then we can choose \( \sigma = \delta^{\frac{2}{\alpha} - 1} \) or \( \sigma = \delta^{(\frac{2}{\alpha} - 1)\mu} \).

(ii) In order to study precisely the case of unbounded test functions (like one in [3]), one would need to solve first the backward Kolmogorov equation in Hölder spaces with weights that are defined by the powers of \( w(x) = (1 + |x|^2)^{1/2}, x \in \mathbb{R}^d \).

Applying Theorem 2 to the model of Example 1 we have

**Proposition 1.** Let \( \alpha < \beta \leq \mu \leq 2\alpha \), and let \( a^{ij}, b^{ij} \in \tilde{C}^{\beta}(\mathbb{R}^d) \), \( G^{ij} \in \tilde{C}^{\beta \wedge 1}(\mathbb{R}^d) \), and

\[
\int |v|^\alpha d\pi + \int |v|^{\mu} \pi(dv) < \infty,
\]

where \( \pi \) is the Lévy measure of the driving process \( Z \). For the approximate Euler scheme in Example 1, there is a constant \( C \) (independent of \( \sigma, \delta \)) such that for all \( g \in \tilde{C}^{\beta}(\mathbb{R}^d) \)

\[
|Eg(\tilde{Y}_T) - Eg(X_T)| \leq C|g|_\beta \delta^{\frac{2}{\alpha} - 1} + \int_{|v| \leq \sigma} |v|^{\beta \wedge 3} d\pi.
\]

2.2. Approximate jump-adapted Euler scheme. As in Example 1 for \( \sigma \in (0, 1) \) we approximate the increments of the driving process

\[
Z_t = \int_0^t \int (1 - \chi_\alpha(v))v_p(ds, dv) + \int_0^t \int \chi_\alpha(v)v_q(ds, dv), t \in [0, T],
\]

by the increments of

\[
\tilde{Z}_t = Z_t^\sigma + R_t^\sigma,
\]

with

\[
Z_t^\sigma = \int_0^t \int_{|v| > \sigma} (1 - \chi_\alpha(v))v_p(ds, dv) + \int_0^t \int_{|v| > \sigma} \chi_\alpha(v)v_q(ds, dv)
\]

and

\[
R_t^\sigma = \begin{cases} 
\frac{t}{\sigma} \int_{|v| \leq \sigma} v_\pi(dv) & \text{if } \alpha < \beta \in (1, 2], \alpha \in (0, 1], \\
B^\sigma \tilde{W}_t & \text{if } \alpha < \beta \in (2, 4], \alpha \in (1, 2], \\
0 & \text{otherwise,}
\end{cases}
\]

where \( B^\sigma \) is the square root of the positive definite \( m \times m \)-matrix \( \left( \int_{|v| \leq \sigma} v_i v_j d\pi \right)_{1 \leq i, j \leq m} \) and \( \tilde{W}_t \) is a standard independent Wiener process in \( \mathbb{R}^m \).
Given $\sigma \in (0,1), \delta > 0$, consider the following $Z^\sigma$-jump adapted time discretization (see [9]): $\tau_0 = 0$,

$$\tau_{i+1} = \inf \{ t > \tau_i : \Delta Z^\sigma_t \neq 0 \} \land (\tau_i + \delta) \land T. \quad (2.5)$$

In this case the time discretization $\{\tau_i, i = 0, \ldots, n_T\}$ of the interval $[0,T]$ is random, $\tau_i$ are stopping times. We approximate $X_t$ by

$$\hat{Y}_t = X_0 + \int_0^t a(\hat{Y}_{\tau_s})ds + \int_0^t b(\hat{Y}_{\tau_s})dW_s + \int_0^t G(\hat{Y}_{\tau_s})d\tilde{Z}_s, t \in [0,T]. \quad (2.6)$$

The following error estimate holds.

**Theorem 3.** Let $\alpha < \beta \leq \mu \leq 2\alpha$, and let $a^i, b^{ij} \in \tilde{C}^\beta(\mathbb{R}^d)$, $G^{ij} \in \tilde{C}^{\beta\vee 1}(\mathbb{R}^d)$, and

$$\int_{|v| \leq 1} |v|^\alpha d\pi + \int_{|v| \geq 1} |v|^\mu \pi(dv) < \infty,$$

where $\pi$ is the Lévy measure of the driving process $Z$.

Then there is a constant $C$ (independent of $\sigma, \delta$) such that for all $g \in \tilde{C}^\beta(\mathbb{R}^d)$

$$|Eg(\hat{Y}_T) - Eg(X_T)| \leq C|g|_\beta \left( (\delta \wedge \lambda^{-1}_\sigma) \tilde{\lambda}_\sigma \right)^{\frac{\alpha}{2} - 1} + \int_{|v| \leq \sigma} |v|^\beta \lambda^3_\sigma d\pi,$$

where $\lambda_\sigma = \pi(\{|v| > \sigma\})$ and

$$\tilde{\lambda}_\sigma = 1 + 1_{\alpha \in (1,2)} \int_{\sigma < |v| \leq 1} vd\pi.$$

In particular, the following statement holds.

**Corollary 4.** Suppose the assumptions of Theorem 3 hold.

(i) If $\delta = T$ (only jump moments are chosen for the time discretization), then

$$|Eg(\hat{Y}_T) - Eg(X_T)| \leq C|g|_\beta \left( \frac{\tilde{\lambda}_\sigma}{\lambda_\sigma} \right)^{\frac{2}{\alpha}} - 1 + \int_{|v| \leq \sigma} |v|^\beta \lambda^3_\sigma d\pi.$$

(ii) If $\sup_{\sigma \in (0,1)} \int_{\sigma < |v| \leq 1} vd\pi < \infty$ for $\alpha \in (1,2)$, then

$$|Eg(\hat{Y}_T) - Eg(X_T)| \leq C|g|_\beta \left( (\delta \wedge \lambda^{-1}_\sigma) \tilde{\lambda}_\sigma \right)^{\frac{\alpha}{2} - 1} + \int_{|v| \leq \sigma} |v|^\beta \lambda^3_\sigma d\pi,$$

where $\lambda_\sigma = \pi(\{|v| > \sigma\})$.

2.3. **Outline of Proof of Theorem 1.** To prove Theorem 1 as in [10] and [12], the solution to the backward Kolmogorov equation associated with $X_t$ is used. First we introduce the operator of the Kolmogorov equation associated with $X_t$. 
For \( u \in \tilde{C}^\beta(H), \beta > \alpha \), denote
\[
L_z u(t, x) = (a(z), \nabla_x u(t, x)) + \frac{1}{2} \sum_{i,j=1}^d (b^i(z), b^j(z)) \partial_{ij}^2 u(x)
\]
\[
+ \int_{\mathbb{R}^m} \left[ u(t, x + G(z)v) - u(t, x) - \chi_\alpha(v)(\nabla_x u(t, x), G(z)v) \right] \pi(dv),
\]
\[
Lu(t, x) = L_x u(t, x) = L_z u(t, x) \big|_{z=x},
\]
where \( b^i(z) = (b^i_j(z))_{1 \leq j \leq m}, i = 1, \ldots, d \).

**Remark 3.** Under assumptions of Theorem 1, there exists a unique strong solution to equation \((1.1)\) and the stochastic process
\[
u(X_t) - \int_0^t Lu(X_s)ds, \forall u \in \tilde{C}^\beta(\mathbb{R}^d)
\]
with \( \beta > \alpha \) is a martingale. The operator \( L \) is the generator of \( X_t \) defined in \((1.1)\).

If \( v(t, x), (t, x) \in H \) satisfies the backward Kolmogorov equation
\[
(\partial_t + L) v(t, x) = 0, \quad 0 \leq t \leq T,
\]
\[
v(T, x) = g(x),
\]
then by Itô’s formula
\[
\mathbb{E}[g(Y_T)] - \mathbb{E}[g(X_T)] = \mathbb{E}[v(T, Y_T) - v(0, Y_0)] = \mathbb{E}\left[ \int_0^T (\partial_t + L_{Y_{t+s}}) v(s, Y_s) ds \right].
\]
The regularity of \( v \) determines the one-step estimate and the rate of convergence of the approximation.

### 3. Backward Kolmogorov Equation

In Lipshitz spaces \( \tilde{C}^\beta(H) \), consider the backward Kolmogorov equation associated with \( X_t \):
\[
(\partial_t + L) u(t, x) = f(t, x),
\]
\[
u(T, x) = g(x).
\]

**Definition 1.** Let \( f, g \) be measurable and bounded functions. We say that \( u \in \tilde{C}^\beta(H) \) with \( \beta > \alpha \) is a solution to \((3.1)\) if
\[
u(t, x) = g(x) + \int_t^T [Lu(s, x) - f(s, x)] ds, \forall (t, x) \in H.
\]

First we show that \( L\tilde{C}^\beta(H) \rightarrow \tilde{C}^{\beta-\alpha}(H) \) is continuous.

**Lemma 1.** Let \( \alpha < \beta \leq \mu \leq 2\alpha \),
\[
\int_{|v| \leq 1} |v|^{\alpha} d\pi + \int_{|v| > 1} |v|^{\mu} d\pi < \infty
\]
and \( a^i, b^ij \in \tilde{C}^\beta(\mathbb{R}^d), G^{ij} \in \tilde{C}^{\beta_1}(\mathbb{R}^d) \). Then for any \( v \in \tilde{C}^\beta(\mathbb{R}^d) \) we have \( Lv \in \tilde{C}^{\beta-\alpha}(\mathbb{R}^d) \) and there is a constant independent of \( v \) such that
\[
|Lv|_{\beta-\alpha} \leq C|v|_\beta.
\]

**Proof.** Let
\[
Bv(x) = \int [v(x + G(x)v) - v(x) - \chi_\alpha(v)(\nabla v(x), G(x)v)] d\pi.
\]
Then
\[
Lv = Bv + (a(x), \nabla v(x)) + \frac{1}{2}(b^i(x), b^i(x))\partial^2_{ij} v(x).
\]
By Proposition 13 in [12], \( Bv \in \tilde{C}^{\beta-\alpha}(\mathbb{R}^d) \) if \( \beta-\alpha \notin \mathbb{N} \) and \( |Bv|_{\beta-\alpha} \leq C|v|_\beta \).

In this case, obviously, \( Lv \in \tilde{C}^{\beta-\alpha}(\mathbb{R}^d) \) as well.

If \( \alpha > 1, \beta = 1 + \alpha \), then
\[
Bv(x) = \int_{|v| \leq 1} \int_0^1 [\nabla v(x + sG(x)v) - \nabla v(x)]G(x)v] d\sigma d\pi
+ \int_{|v| > 1} [v(x + G(x)v) - v(x)] d\pi.
\]
Since
\[
\nabla(Bv(x)) = \int_{|v| \leq 1} \int_0^1 [\partial^2 v(x + sG(x)v) - \partial^2 v(x)]G(x)v] d\sigma d\pi
+ \int_{|v| \leq 1} \int_0^1 \partial^2 v(x + sG(x)v)\nabla G(x)vG(x)v] d\sigma d\pi
+ \int_{|v| > 1} [\nabla v(x + G(x)v) - \nabla v(x)] d\pi
+ \int_{|v| > 1} \nabla v(x + G(x)v)\nabla G(x)v d\pi,
\]
it follows that \( \sup_x |\nabla(Bv(x))| \leq C|v|_\beta \). Therefore \( |Lv|_{\beta-\alpha} \leq C|v|_\beta \) as well.

If \( \alpha = 1 \) and \( \beta = 2 \), then
\[
|\nabla Bv(x)| = \int [\nabla v(x + G(x)v) - \nabla v(x)] d\pi + \int \nabla v(x + G(x)v)G(x)v d\pi,
\]
\[
\sup_x |\nabla Bv(x)| \leq C|v|_\beta
\]
and \( |Lv|_{\beta-\alpha} \leq C|v|_\beta \). The case \( \beta = 4, \alpha = 2 \) is considered in a similar way.

The main result of this section is the following statement.

**Theorem 4.** Let \( \alpha < \beta \leq \mu \leq 2\alpha \), and
\[
\int_{|v| \leq 1} |v|^{\alpha \pi} dv + \int_{|v| > 1} |v|^{\mu \pi} dv < \infty.
\]
Assume $a^i, b^{ij} \in \tilde{C}^\beta(R^d), G^{ij} \in \tilde{C}^\beta \cap L^1(R^d)$. Then for each $f \in \tilde{C}^\beta(R^d), g \in \tilde{C}^\beta(R^d)$, there exists a unique solution $u \in \tilde{C}^\beta(H)$ to (3.1) and a constant $C$ independent of $f, g$ such that $|u|_\beta \leq C(|f|_\beta + |g|_\beta)$.

To prove Theorem 4, for $\varepsilon \in (0, 1)$ we consider a non-degenerate equation

(3.3) \quad \left( \partial_t + L^\varepsilon \right) u(t, x) = f(t, x), \\
\quad u(T, x) = g_\varepsilon(x),

where $L^\varepsilon u = -\varepsilon^\alpha (-\Delta)^{\alpha/2} u + Lu$ and

$$g_\varepsilon(x) = \int g(y) w^\varepsilon(x - y) dy = \int g(x - y) w^\varepsilon(y) dy, x \in R^d$$

with $w^\varepsilon(x) = \varepsilon^{-d} w(x/\varepsilon), x \in R^d, w \in C_0^\infty(R^d), \int w dx = 1$.

An obvious consequence of Corollary 9 in [12] is the following statement.

**Lemma 2.** (see Corollary 9 in [12]) Let $\alpha < \beta \leq \mu \leq 2\alpha$,

$$\int_{|v| \leq 1} |v|^\alpha \pi(dv) + \int_{|v| > 1} |v|^\mu \pi(dv) < \infty,$$

and $a^i, b^{ij}, f, g \in \tilde{C}^\beta(R^d), G^{ij} \in \tilde{C}^\beta \cap L^1(R^d)$. Then for each $\varepsilon \in (0, 1)$ there is $\bar{\beta} > 2\alpha$ and a unique $u = u_\varepsilon \in \tilde{C}^\beta(H)$ solving (3.3).

We separate in the operator $L^\varepsilon$ its "bounded jump" part $L^\varepsilon v(x) = \tilde{L}^\varepsilon v(x)|_{z=x}$ with

$$\tilde{L}^\varepsilon v(x) = -\varepsilon^\alpha (-\Delta)^{\alpha/2} u + (a(z), \nabla_x v(x))$$

$$+ \frac{1}{2} \sum_{i,j=1}^d (b^i(z), b^j(z)) \partial_{ij}^2 v(x)$$

$$+ \int_{|v| \leq 1} [v(x + G(z)v) - v(x) - \chi_\alpha(v)(\nabla v(x), G(z)v)] d\pi,$$

$z, x \in R^d, v \in C_0^\infty(R^d)$, so that

$$L^\varepsilon v(x) = \tilde{L}^\varepsilon v(x) + \int_{|v| > 1} [v(x + G(z)v) - v(x)] d\pi, x, z \in R^d.$$

**Remark 4.** If the assumptions of Lemma 2 hold and $u_\varepsilon \in \tilde{C}^\beta(H)$ solves (3.3) with $\bar{\beta} > 2\alpha$, then $u_\varepsilon$ satisfies the following equation as well:

(3.4) \quad \left( \partial_t + L^\varepsilon \right) u(t, x) = F(u, t, x), \\
\quad u(T, x) = g_\varepsilon(x),

where $F(u, t, x) = F_z(u, t, x)|_{z=x}$ with

$$F_z(u, t, x) = f(t, x) - \int_{|v| > 1} [u(t, x + G(z)v) - u(t, x)] d\pi.$$
Using a probabilistic form of a maximum principle we will derive uniform (independent of \( \varepsilon \)) \( \tilde{C}^\beta \)-norm estimates of \( u_\varepsilon \) and passing to the limit as \( \varepsilon \to 0 \) we will obtain \( u \in \tilde{C}^\beta(H) \) solving (3.1). First we prove some auxiliary statements.

Let

\[
\tilde{Z}_t = \int_0^t \int_{|v| \leq 1} [(1 - \chi_\alpha(v))\nu p(dt, dv) + \chi_\alpha(v)\nu q(dt, dv)]
\]

(3.5)

\[
= \int_0^t \int_{|v| \leq 1} vq(dt, dv) + t \int_{|v| \leq 1} (1 - \chi_\alpha(v))vd\pi.
\]

For \((s, x) \in H, h \in \mathbb{R}^d, \xi \in \mathbb{R}^d\), the following stochastic processes in \([s, T]\) are used to derive the uniform estimates:

\[
dU_t = \varepsilon dZ_t^\alpha + a(U_t)dt + b(U_t)dW_t + G(U_{t-})d\tilde{Z}_t,
\]

\[
dH_t = [a(U_t + H_t) - a(U_t)]dt + [b(U_t + H_t) - b(U_t)]dW_t
\]

(3.6)

\[
+ [G(U_{t-} + H_{t-}) - G(U_{t-})]d\tilde{Z}_t,
\]

\[
d\tilde{V}_t = a^{(1)}(U_t + H_t; \tilde{V}_t)dt + b^{(1)}(U_t + H_t; \tilde{V}_t)dW_t
\]

\[
+ \int_{|v| \leq 1} G^{(1)}(U_{t-} + H_{t-}; \tilde{V}_{t-})d\tilde{Z}_t,
\]

\[
dV_t = a^{(1)}(U_t; V_t)dt + b^{(1)}(U_t; V_t)dW_t + G^{(1)}(U_{t-}; V_{t-})d\tilde{Z}_t,
\]

\[U_s = x, H_s = h, V_s = \xi, \tilde{V}_s = \xi,\]

where \( Z^\alpha \) is \( \mathbb{R}^d \)-valued spherically symmetric \( \alpha \)-stable process corresponding to \((-\Delta)^{\alpha/2}\) and independent of \( Z \). Recall for a function \( v \) on \( \mathbb{R}^d \) we denote \( v^{(1)}(x; \xi) = (\nabla v(x), \xi), x, \xi \in \mathbb{R}^d \) and, for example, componentwise,

\[
dV_t^j = (\nabla a^{(j)}(U_t), V_t)dt + \sum_{i=1}^n (\nabla b^{ji}(U_t), V_t)dW_t^i + \sum_{i=1}^m (\nabla G^{ji}(U_{t-}), V_{t-})d\tilde{Z}_t^i,
\]

\[j = 1, \ldots, d.\]

**Lemma 3.** (a) If \( a^i, b^i, G^{ij} \in \tilde{C}^1(\mathbb{R}^d) \), then for each \( l \geq 2 \) there is a constant \( C \) such that

\[
E[\sup_{s \leq t \leq T}|H_t|^l] \leq C|h|^l.
\]

(b) If \( a^i, b^i, G^{ij} \in \tilde{C}^{1+\kappa}(\mathbb{R}^d) \) with \( \kappa \in (0, 1) \), then for each \( l \geq 2 \) there is a constant \( C \) such that

\[
E[\sup_{s \leq t \leq T}|V_s|^l] + E[\sup_{s \leq t \leq T}|\tilde{V}_s|^l] \leq C|\xi|^l,
\]

\[
E[\sup_{s \leq t \leq T}|V_t - \tilde{V}_t|^l] \leq C|\xi|^l|h|^{lk}.
\]
Proof. (a) Since (3.5) holds, we have by H"older inequality and martingale moment estimates (see [11], [17])
\[
\mathbb{E} \sup_{s \leq r \leq t} |H_r|^l \leq C|h|^l + \mathbb{E}[\left( \int_s^t |H_r|^2 dr \right)^{l/2}] + \mathbb{E}[\int_s^t |H_r|^l dr], s \leq t \leq T.
\]
and inequality follows by Gronwall lemma.
(b) Similarly, for each \( l \geq 2 \), there is a constant \( C \) so that
\[
\mathbb{E}[\sup_{s \leq t \leq T} |V_r|^l + \sup_{s \leq t \leq T} |\bar{V}_r|^l] \leq C|\xi|^l.
\]
Then
\[
\mathbb{E} \sup_{s \leq r \leq t} |V_r - \bar{V}_r|^l \leq C[\mathbb{E}[\left( \int_s^t |H_r|^{2l}|\bar{V}_r|^2 dr \right)^{l/2}] + \mathbb{E}[\int_s^t |H_r|^l|\bar{V}_r|^l dr]
\]
\[
+ \mathbb{E}[\left( \int_s^t |\bar{V}_r - V_r|^2 dr \right)^{l/2}] + \mathbb{E}[\int_s^t |\bar{V}_r - V_r|^l dr]
\]
\[
\leq C[\mathbb{E}\int_s^t |H_r|^{2l}|\bar{V}_r|^l dr + \mathbb{E}\int_s^t |\bar{V}_r - V_r|^l dr], s \leq t \leq T.
\]
By Gronwall lemma,
\[
\mathbb{E} \sup_{s \leq r \leq t} |V_r - \bar{V}_r|^l \leq C\mathbb{E}\int_s^t |H_r|^{2l}|\bar{V}_r|^l dr
\]
\[
\leq C\int_s^t [\mathbb{E}(|H_r|^{2\zeta})]^{1/2}[\mathbb{E}(|\bar{V}_r|^{2l})]^{1/2}] dr
\]
\[
\leq C|\xi|^l|h|^\zeta.
\]
\[\square\]

3.1. **Proof of Theorem 4.** 1. **Existence.** By Lemma 2, for each \( \varepsilon \in (0,1) \) there is a unique solution \( u_\varepsilon \in \check{C}^\beta(H) \) to (3.3) for some \( \beta > 2\alpha \). By Remark 4.3.1 holds as well. Let \((s, x) \in H \) and \( U_t \) solves (3.6). By Itô formula,
\[
\mathbb{E}g_\varepsilon(U_T) - u_\varepsilon(s, x) = \mathbb{E}\int_s^T F(u_\varepsilon, r, U_r) dr
\]
and
\[
|u_\varepsilon(s, \cdot)|_0 \leq |g|_0 + \int_s^T (|f(r, \cdot)|_0 + C|u_\varepsilon(r, \cdot)|_0) dr.
\]
By Gronwall lemma, there is a constant not depending on \( u_\varepsilon \) and \( \varepsilon \) such that
\[
\sup_{0 \leq t \leq T} |u_\varepsilon(t, \cdot)|_0 \leq C[|g|_0 + \int_0^T |f(r, \cdot)|_0 dr].
\]
As suggested in [7], we estimate multilinear forms associated to the derivatives of $u$. Let $k = [\beta]$, $(t, x) \in H, \xi^1, \ldots, \xi^k \in \mathbb{R}^d$ and

$$u^{(k)}_\varepsilon(t, x; \xi^1, \ldots, \xi^k) = \sum_{i_1, \ldots, i_k = 1}^d \frac{\partial^k u(t, x)}{\partial x_{i_1} \cdots x_{i_k}} \xi^1_{i_1} \cdots \xi^k_{i_k} \text{ if } k \geq 1,$$

$$u^{(0)}_\varepsilon(t, x) = u(t, x).$$

For $z \in \mathbb{R}^d, (t, x) \in H, \xi^1 \in \mathbb{R}^d, \ldots, \xi^k \in \mathbb{R}^d$, let

$$p z u^{(k)}_\varepsilon(t, x; \xi^1, \ldots, \xi^k) = -\varepsilon^\alpha (-\Delta)^{\alpha/2} u^{(k)}_\varepsilon(t, x; \xi^1, \ldots, \xi^k)
+ \int_{|z| \leq 1} \{ u^{(k)}_\varepsilon(t + G(z)v; \xi^1 + G(1)(z; \xi^1)v, \ldots, \xi^k + G(1)(z; \xi^k)v) - u^{(k)}_\varepsilon(t; \xi^1, \ldots, \xi^k) \}
- \chi_\alpha(v)[(\nabla x u^{(k)}_\varepsilon(t; \xi_1, \ldots, \xi^k), G(z)v) - \sum_{l=1}^k (\nabla x u^{(k)}_\varepsilon(t; \xi_1, \ldots, \xi^k), G(1)(z; \xi^l)v)] d\pi
+ (a(z), \nabla x u^{(k)}_\varepsilon(t; \xi^1, \ldots, \xi^k)) + \sum_{l=1}^k (\nabla x \xi^l u^{(k)}_\varepsilon(t; \xi^1, \ldots, \xi^k), a(1)(z; \xi^l))
+ \frac{1}{2} \sum_{i,j} \{(b^i(z), b^j(z)) \partial^2_{\xi^i \xi^j} u^{(k)}_\varepsilon(t; \xi^1, \ldots, \xi^k)
+ \sum_{l=1}^k (b^i(z; \xi^l), b^j(z)) \partial_{\xi^i \xi^j}^2 u^{(k)}_\varepsilon(t; \xi^1, \ldots, \xi^k)
+ (b^i(z), b^i(z; \xi^1)) \partial_{\xi^i z_j}^2 u^{(k)}_\varepsilon(t; \xi^1, \ldots, \xi^k)) \}.$$

Differentiating both sides of (3.4) and multiplying by $\xi^1_{i_1} \cdots \xi^k_{i_k}$ we see that $u^{(k)}_\varepsilon(t, x; \xi^1, \ldots, \xi^k)$ satisfies the equation

$$\partial u^{(k)}_\varepsilon(t, x, \xi^1, \ldots, \xi^k) + p \varepsilon u^{(k)}_\varepsilon(t, x, \xi^1, \ldots, \xi^k) = A(u, t, x, \xi^1, \ldots, \xi^k),$$

where

$$A(u, t, x, \xi^1, \ldots, \xi^k) = B(u, t, x, \xi^1, \ldots, \xi^k) + P^{(k)}(u, t, x; \xi^1, \ldots, \xi^k)$$

and $B(u, t, x, \xi^1, \ldots, \xi^k)$ is a finite sum of the terms of the form

$$[\nabla x u^{(l)}_\varepsilon(t + G(x)v; \xi^{i_1}, \ldots, \xi^{i_l}) - \nabla x u^{(l)}_\varepsilon(t, x + G(x)v; \xi^{i_1}, \ldots, \xi^{i_l})] \times G^{(k-l)}(x; \xi^{i_{l+1}}, \ldots, \xi^{i_k})v
= \int_0^1 \partial^2 u^{(l)}_\varepsilon(t, x + sG(x)v; \xi^{i_1}, \ldots, \xi^{i_l}) G(x)v ds G^{(k-l)}(x; \xi^{i_{l+1}}, \ldots, \xi^{i_k})v$$

with $l \leq k - 2$ and

$$u^{(l)}_\varepsilon(t, x + G(x)v; \xi^{i_1}, \ldots, \xi^{i_l}) G^{(l_1)}(x; \xi^{i_1}, \ldots, \xi^{i_{l_1}}) \cdots G^{(l_m)}(x; \xi^{i_m}, \ldots, \xi^{i_{l_m}})$$
with \( m \geq 2, l \leq k, \ell + l_1 + \ldots + l_m = k \) and \((\xi^1, \ldots, \xi^l, \ldots, \xi^{km})\) being a permutation of \( \xi^1, \ldots, \xi^k \). In any case, there is a constant \( C \) independent of \( \varepsilon \) and \( u_\varepsilon \) so that for all \((t, x) \in [0, T] \times \mathbb{R}^d, \xi^i \in \mathbb{R}^d, \)

\[
\begin{align*}
\tag{3.8}
|A(u_\varepsilon, t, x, \xi^1, \ldots, \xi^k)| & \leq C(|u_\varepsilon(t, \cdot)|_k + |f(t, \cdot)|)[|\xi^1| \ldots |\xi^k|, \\
A(u_\varepsilon, t, \cdot, \xi^1, \ldots, \xi^k)|_{\beta - k} & \leq C(|u_\varepsilon(t, \cdot)|_k + |f(t, \cdot)|)[|\xi^1| \ldots |\xi^k|],
\end{align*}
\]

and

\[
\begin{align*}
\tag{3.9}
|A(u_\varepsilon, t, x, \xi^1, \ldots, \xi^k) - A(u_\varepsilon, t, x\xi^1, \ldots, \xi^k)| & \leq C(|f(t, \cdot)|_k + |u_\varepsilon(t, \cdot)|_k) \sum_{l=1}^k |\xi^1| \ldots |\xi^{l-1}||\xi^l| - |\xi^1| |\xi^{l+1}| \ldots |\xi^k|).
\end{align*}
\]

On the other hand, for any \((s, x) \in H\) with the processes defined in (3.6), it follows by Itô formula,

\[
\begin{align*}
\mathbb{E}[u_\varepsilon^{(k)}(T, U_T, V_T^1, \ldots, V_T^k) - u_\varepsilon^{(k)}(s, x, \xi^1, \ldots, \xi^k)]
& = \mathbb{E}[g^{(k)}(U_T, V_T^1, \ldots, V_T^k) - u_\varepsilon^{(k)}(s, x, \xi^1, \ldots, \xi^k)] \\
& = \mathbb{E} \int_s^T \left[ \partial_x u_\varepsilon^{(k)}(t, U_t, V_t^1, \ldots, V_t^k) + \mathcal{P}_{U_t} u_\varepsilon^{(k)}(t, U_t, V_t^1, \ldots, V_t^k) \right] dt \\
& = \mathbb{E} \int_s^T A(u_\varepsilon, t, U_t, V_t^1, \ldots, V_t^k) dt
\end{align*}
\]

and

\[
\begin{align*}
\mathbb{E}[u_\varepsilon^{(k)}(T, U_T + H_T, \bar{V}_T^1, \ldots, \bar{V}_T^k) - u_\varepsilon^{(k)}(T, U_T, V_T^1, \ldots, V_T^k)]
& = \mathbb{E}[g^{(k)}(U_T + H_T, \bar{V}_T^1, \ldots, \bar{V}_T^k) - g^{(k)}(U_T, V_T^1, \ldots, V_T^k)] \\
& = \mathbb{E} \int_s^T \left[ \partial_x u_\varepsilon^{(k)}(t, U_t + H_t, \bar{V}_t^1, \ldots, \bar{V}_t^k) + \mathcal{P}_{U_t + H_t} u_\varepsilon^{(k)}(t, U_t + H_t, \bar{V}_t^1, \ldots, \bar{V}_t^k) \right] dt \\
& = \mathbb{E} \int_s^T A(u_\varepsilon, t, U_t + H_t, \bar{V}_t^1, \ldots, \bar{V}_t^k) \right] dt
\end{align*}
\]

Since by (3.8)

\[
|A(u_\varepsilon, t, U_t, V_T^1, \ldots, V_T^k)| \leq C(|u_\varepsilon(t, \cdot)|_k + |f(t, \cdot)|_k)[|V_T^1| \ldots |V_T^k|, \\

it follows by Lemma 3 and Hölder inequality,

\[
\tag{3.10}
\mathbb{E}|A(u_\varepsilon, t, U_t, V_T^1, \ldots, V_T^k)| \leq C(|u_\varepsilon(t, \cdot)|_k + |f(t, \cdot)|_k)[|\xi^1| \ldots |\xi^k|].
\]
Since
\[|A(u_\varepsilon, t, U_t + H_t, \bar{V}_t^1, \ldots, \bar{V}_t^k) - A(u_\varepsilon, t, U_t, V_t^1, \ldots, V_t^k)|\]
\[\leq |A(u_\varepsilon, t, U_t + H_t, \bar{V}_t^1, \ldots, \bar{V}_t^k) - A(u_\varepsilon, t, U_t, \bar{V}_t^1, \ldots, \bar{V}_t^k)|\]
\[+ |A(u_\varepsilon, t, U_t, \bar{V}_t^1, \ldots, \bar{V}_t^k) - A(u_\varepsilon, t, U_t, V_t^1, \ldots, V_t^k)| = A_1 + A_2,\]
it follows by the estimates (3.8), (3.9) and Lemma 3 that
\[E A_1 \leq C(E|H_t|^2(\beta-k)/2)|f(t, \cdot)|_\beta + |u(t, \cdot)|_\beta\]
\[\leq C|h|^\beta-k(|f(t, \cdot)|_\beta + |u(t, \cdot)|_\beta).\]
and for $|h| \leq 1$
\[E A_2 \leq C(|f(t, \cdot)|_k + |u(t, \cdot)|_k)\sum_{l=1}^k E|V_l^1| \ldots |V_{l-1}^l||\bar{V}_l^l - V_l^l||V_{l+1}^l \ldots |V_k^k)|\]
\[\leq C(|f(t, \cdot)|_k + |u(t, \cdot)|_k)\sum_{l=1}^k (E[|\bar{V}_l^l - V_l^l|^2])^{1/2} |\xi^1| \ldots |\xi^{l-1}| |\xi^{l+1}| \ldots |\xi^k|\]
\[\leq C(|f(t, \cdot)|_k + |u(t, \cdot)|_k)|\xi^1| \ldots |\xi^k||h|^\beta-k.\]

Similarly, we estimate
\[E |g^{(k)}(U_T, V_T^1, \ldots, V_T^k)| \leq C|g|_k |\xi^1| \ldots |\xi^k| \]
and for $|h| \leq 1$
\[E |g^{(k)}(U_T + H_T, \bar{V}_T^1, \ldots, \bar{V}_T^k) - g^{(k)}(U_T, V_T^1, \ldots, V_T^k)|\]
\[\leq C|g|_\beta |h|^\beta-k |\xi^1| \ldots |\xi^k|.\]

So,
\[|u_\varepsilon^{(k)}(s, x; \xi^1, \ldots, \xi^k)|_0 \leq C|\xi^1| \ldots |\xi^k| |g|_k + \int_{s}^{T} (|u_\varepsilon(t, \cdot)|_k + |f(t, \cdot)|_k) dt, 0 \leq s \leq T,\]
and by Gronwall lemma,
\[\sup_{0 \leq s \leq T} |u_\varepsilon^{(k)}(s, x; \xi^1, \ldots, \xi^k)|_0 \leq C|\xi^1| \ldots |\xi^k| |g|_k + \int_{0}^{T} |f(t, \cdot)|_k dt].\]

Also, for $|h| \leq 1, x \in \mathbb{R}^d, 0 \leq s \leq T,$
\[|u_\varepsilon^{(k)}(s, x + h, \xi^1, \ldots, \xi^k) - u_\varepsilon^{(k)}(s, x, \xi^1, \ldots, \xi^k)| \]
\[\leq C|h|^\beta-k |\xi^1| \ldots |\xi^k| |g|_\beta + \int_{s}^{T} (|f(t, \cdot)|_\beta + |u(t, \cdot)|_\beta) dt,\]
and by Gronwall lemma,
\[
\sup_{0 \leq s \leq T} |u^{(k)}(s, \xi^1, \ldots, \xi^k)|_{\beta-k} \\
\leq C|\xi^1| \cdots |\xi^k| |g|_{\beta} + \int_0^T |f(t, \cdot)|_{\beta} dt
\]
Therefore for each \( \beta \in (\alpha, 2\alpha) \),
\[
(3.11) \quad \sup_{\varepsilon \in (0,1)} |u_\varepsilon|_{\beta} \leq C|g|_{\beta} + \int_0^T |f(t, \cdot)|_{\beta} dt.
\]
Since for each \((s, x) \in H\),
\[
(3.12) \quad u_\varepsilon(s, x) = g_\varepsilon(x) + \int_s^T [L_{\varepsilon} u_\varepsilon(t, x) - f(t, x)] dt,
\]
and there is a constant \( C > 0 \) so that for all \((t, x) \in H, h \in \mathbb{R}^d\),
\[
(3.13) \quad |\partial_t u_\varepsilon(t, x + h) - \partial_t u_\varepsilon(t, x)| \\
\leq |L_{\varepsilon} u_\varepsilon(t, x + h) - L_{\varepsilon} u_\varepsilon(t, x)| + |f(t, x + h) - f(t, x)| \\
\leq C|h|^{\tilde{\beta} - \alpha} (|u_\varepsilon|_{\tilde{\beta}} + |f|_{\beta})
\]
for some \( \tilde{\beta} \in (\alpha, \alpha + \alpha \wedge 1) \). It follows from \( (3.11) \) and \( (3.13) \) that there is a sequence \( \varepsilon_n \to 0 \) and \( u \in \tilde{C}^{\beta}(H) \) such that such \( u_{\varepsilon_n} \to u \) uniformly on compact sets of \( H \). By \( (3.11) \), \( L_{\varepsilon} u_\varepsilon(t, x) \to Lu(t, x) \) pointwise and passing to the limit in \( (3.12) \), we see that \( u \in \tilde{C}^{\beta}(H) \) is a solution to \( (3.1) \).

2. Uniqueness. Let \( u^1, u^2 \in \tilde{C}^{\beta}(H) \) be two solutions to \( (3.1) \). Then \( v = u^1 - u^2 \) satisfies \( (3.1) \) with \( g = 0, f = 0 \). Let \( X^{s,x}_t \) be the solution to \( (1.1) \) starting from \( x \in \mathbb{R}^d \) at time moment \( s \). Then by Itô formula,
\[
-v(s, x) = \mathbb{E} v(T, X^{s,x}_T) - v(s, x) \\
= \mathbb{E} \int_s^T [\partial_t v(r, X^{s,x}_r) + Lv(r, X^{s,x}_r)] dr = 0
\]
and uniqueness follows.

4. One-Step Estimate and Proof of Main Results

First, we modify the mollified function estimates for the Lipshitz spaces. Let \( w \in C_0^\infty(\mathbb{R}^d) \), be a nonnegative smooth function with support in \( \{|x| \leq 1\} \) such that \( w(x) = w(|x|), x \in \mathbb{R}^d \), and \( \int w(x) dx = 1 \). Due to the symmetry,
\[
(4.1) \quad \int_{\mathbb{R}^d} x^i w(x) dx = 0, i = 1, \ldots, d.
\]
For \( x \in \mathbb{R}^d \) and \( \varepsilon \in (0,1) \), define \( w^\varepsilon(x) = \varepsilon^{-d} w(\frac{x}{\varepsilon}) \) and the convolution
\[
(4.2) \quad f^\varepsilon(x) = \int f(y) w^\varepsilon(x-y) dy = \int f(x-y) w^\varepsilon(y) dy, x \in \mathbb{R}^d.
\]
Lemma 4. Let $\alpha < \beta \leq 2\alpha$, $f \in \tilde{C}^{\beta-\alpha}(\mathbb{R}^d)$. Then
\begin{equation}
|f(x) - f(x)| \leq C\varepsilon^{\beta-\alpha}|f|_{\beta-\alpha}, x \in \mathbb{R}^d,
\end{equation}
and there is a constant $C$ such that
\begin{equation}
|Lf| \leq C\varepsilon^{\beta-2\alpha}|f|_{\beta-\alpha}.
\end{equation}

Proof. Indeed, if $\beta - \alpha \leq 1$, then
$$|f(x) - f(x)| \leq \int |f(x - y) - f(x)|w^\varepsilon(y)dy, \leq C|f|_{\beta-\alpha}\varepsilon^{\beta-\alpha}.$$ 
If $\beta - \alpha \in (1, 2]$, then
$$|f(x) - f(x)| = \int f(x + y) - f(x) - (\nabla f(x), y)w^\varepsilon(y)dy| \leq \int_0^1 |\nabla f(x + sy) - \nabla f(x)|dw^\varepsilon(y)dydy \leq C\varepsilon^{\beta-\alpha}|f|_{\beta-\alpha}.$$ 

According to Lemma 17 (iii) and Corollary 18 in [12], for each $\beta$ so that $\beta - \alpha < \alpha$
$$|Lf| \leq C\varepsilon^{(\beta-\alpha)-\alpha}|f|_{\beta-\alpha} = C\varepsilon^{\beta-2\alpha}|f|_{\beta-\alpha}.$$ 
The inequality (4.4) still holds for $\beta - \alpha = \alpha$ or $\beta = 2\alpha$ by a straightforward estimate.

We modify one-step estimate in [12] for Lipschitz spaces as well.

Lemma 5. Let $\alpha < \beta \leq \mu \leq 2\alpha$,
$$\int_{|v| \leq 1} |v|^\alpha d\pi + \int_{|v| > 1} |v|^\mu d\pi < \infty,$$
and $a^i, b^ij \in \tilde{C}^\alpha(\mathbb{R}^d), G^{ij} \in \tilde{C}^{\beta/2}(\mathbb{R}^d)$. Then there exists a constant $C$ such that for all $f \in \tilde{C}^{\beta-\alpha}(\mathbb{R}^d)$,
$$|E[f(Y_s) - f(Y_{\tau_{i_s}})|F_{\tau_{i_s}}]| \leq C|f|_{\beta-\alpha}\delta^{\beta-\alpha-1}, \forall s \in [0, T],$$
where $i_s = i$ if $\tau_i \leq s < \tau_{i+1}$.

Proof. Applying Itô’s formula, for $s \in [0, T]$,
$$E[f(Y_s) - f(Y_{\tau_{i_s}})|F_{\tau_{i_s}}] = E[\int_{\tau_{i_s}}^s (LY_{r_s}^f(Y_r))dr|F_{\tau_{i_s}}].$$
Hence, for $\varepsilon \in (0, 1)$, by (4.3) and (4.4),
$$|E[f(Y_s) - f(Y_{\tau_{i_s}})|F_{\tau_{i_s}}]| \leq |E[(f - f^\varepsilon)(Y_s) - (f - f^\varepsilon)(Y_{\tau_{i_s}})|F_{\tau_{i_s}}]| + |E[f^\varepsilon(Y_s) - f^\varepsilon(Y_{\tau_{i_s}})|F_{\tau_{i_s}}]|$$
$$\leq CF(\varepsilon, \delta)|f|_{\beta-\alpha},$$
with a constant \( C \) independent of \( \varepsilon, f \) and \( F(\varepsilon, \delta) = \varepsilon^{\beta-\alpha} + \varepsilon^{\beta-2\alpha} \delta \). Minimizing \( F(\varepsilon, \delta) \) in \( \varepsilon \in (0, 1) \), we obtain
\[
|\mathbb{E}[f(Y_s) - f(Y_{\tau_{is}})]| \leq C \delta^{\frac{\alpha}{\beta-1}} |f|_\beta.
\]

\[\square\]

4.1. Proof of Theorem 1. Let \( u \in \tilde{C}^\beta(H) \) be the unique solution to \((3.1)\) with \( f = 0 \). By Itô’s formula,
\[
\mathbb{E}[u(0, X_0)] = \mathbb{E}[u(T, X_T)] - \mathbb{E}\left[ \int_0^T (\partial_t u(s, X_s) + L_X u(s, X_s)) ds \right]
\]
and
\[
\mathbb{E}[u(0, X_0)] = \mathbb{E}[u(0, Y_0)].
\]

By Lemma 1,
\[
|L_z u(s, \cdot)|_{\beta-\alpha} \leq C |g|_\beta, \quad \mathbb{E}[\partial_t u(s, X_s) - \partial_t u(s, Y_{\tau_{is}})]
\]
and
\[
|L_{Y_{\tau_{is}}} u(s, X_s) - L_{Y_{\tau_{is}}} u(s, Y_{\tau_{is}})| \leq C \delta^{\frac{\alpha}{\beta-1}} |g|_\beta.
\]

Hence, by \((4.6)\) and Lemma 5, there exists a constant \( C \) independent of \( g \) such that
\[
|\mathbb{E}g(Y_T) - \mathbb{E}g(X_T)| \leq C \delta^{\frac{\alpha}{\beta-1}} |g|_\beta.
\]
The statement of Theorem 1 follows.

4.1.1. Proof of Corollary 2. According to [2], there is a rapidly decreasing smooth function \( w \in S(\mathbb{R}^d) \), the Schwartz space, such that \( \int w(x) dx = 1 \) and all moments are zero:
\[
\int w(x) x^\gamma dx = 0, \gamma \in \mathbb{N}^d, \gamma \neq 0,
\]
where \( x^\gamma = x_1^{\gamma_1} \ldots x_d^{\gamma_d}, x = (x_1, \ldots, x_d) \in \mathbb{R}^d \). Let \( \varepsilon \in (0, 1), w_{\varepsilon}(x) = \varepsilon^{-d} w(x/\varepsilon), x \in \mathbb{R}^d \),
\[
g_{\varepsilon}(x) = \int g(x - y) w_{\varepsilon}(y) dy, x \in \mathbb{R}^d.
\]

We will show that for \( \beta \in (0, 4], \nu \leq \beta, \)
\[
\sup_x |g_{\varepsilon}(x) - g(x)| \leq C |g|_\nu \varepsilon^\nu,
\]
\[
|g_{\varepsilon}|_\beta \leq C \varepsilon^{\nu-\beta} |g|_\nu.
\]
Obviously, \( \tilde{Z}_t = Z_t^\alpha + R_t^\alpha, \) \( 0 \leq t \leq T, \) in Example 1. Obviously, \( \tilde{Z}_t \) depends on \( \alpha, \beta \) and \( \sigma. \) Its generator is

\[
\tilde{L}v(x) = \int_0^t \int_{|v| \leq \sigma} [v(s, x + v) - v(s, x) - \chi_\alpha(v) (\nabla v(s, x), v)]\pi(dv)
\]

\[+ R^{\alpha, \beta} v(x), \]

where

\[
R^{\alpha, \beta} v(x) = \begin{cases} \int_{|v| \leq \sigma} (\nabla v(x), v) d\pi & \text{if } \alpha < \beta \in (1, 2], \alpha \in (0, 1], \\
\frac{1}{2} \sum_{i,j} (B^\alpha B^\beta)_{ij} \partial_{ij} v(x) & \text{if } \alpha < \beta \in (2, 4], \alpha \in (1, 2], \\
0 & \text{otherwise.} \end{cases}
\]

**Lemma 6.** Let \( \alpha < \beta \leq 2\alpha \) and \( h \in \hat{C}^\beta(\mathbb{R}^d). \) Then there is a constant \( C \) such that for every \( \mathbb{F} \)-stopping times \( 0 \leq \tau \leq \tau' \leq T \) we have

\[
|\mathbb{E}[h(\hat{Z}_{\tau'} - Z_{\tau}) - h(\tilde{Z}_{\tau'} - \tilde{Z}_{\tau})]| \leq C \phi(\sigma) |h|_\beta \mathbb{E}[\tau' - \tau | \mathcal{F}_\tau],
\]
with 
\[ \phi(\sigma) = \int_{|v| \leq \sigma} |v|^{\beta \wedge 3} d\pi \]
(here \(\mathbb{F}^Z\) is the natural filtration of \(\sigma\)-algebras generated by \(Z\)).

**Proof.** Let \(\tilde{Z}^\sigma = Z - Z^\sigma\). We show first that there is a constant \(C\) such that for any \(s < t, g \in \bar{C}\beta(\mathbb{R}^d)\),

\[
|Eg(\tilde{Z}_t^\sigma - \tilde{Z}_s^\sigma) - Eg(R_t^\sigma - R_s^\sigma)| \leq C\phi(\sigma)|g|_{\beta}|t - s|.
\]

By Ito formula
\[
v(r, x) = Eg(\tilde{Z}_t^\sigma - \tilde{Z}_s^\sigma + x), 0 \leq r \leq t,
\]
is the solution of the backward Kolmogorov equation

\[
\partial_t v(r, x) + \int_{|v| \leq \sigma} [v(r, x + v) - v(r, x) - \chi_\alpha(v) (\nabla v(r, x), v)] \pi(dv) = 0, v(t, x) = g(x), 0 \leq s \leq t.
\]

Obviously, \(v \in \bar{C}\beta([0, t] \times \mathbb{R}^d)\) and (see (4.9)) \(|v|_{\beta} \leq |g|_{\beta}\). By Ito formula and (4.10),

\[
Eg(R_t^\sigma - R_s^\sigma) - Eg(\tilde{Z}_t^\sigma - \tilde{Z}_s^\sigma) = \mathbf{E} v(t, R_t^\sigma - R_s^\sigma) - v(s, 0) = \mathbf{E} \int_s^t \left[ R^{\alpha, \beta} v(r, R_r^\sigma - R_s^\sigma) - \tilde{L} v(r, R_r^\sigma - R_s^\sigma) \right] dr,
\]

where \(\tilde{L} v(r, x) = \int_{|v| \leq \sigma} [v(r, x + v) - v(r, x) - \chi_\alpha(v) (\nabla v(r, x), v)] \pi(dv), (r, x) \in H\).

If \(\alpha < \beta \in (1, 2], \alpha \in (0, 1]\), then for all \((r, x) \in H\),

\[
|R^{\alpha, \beta} v(r, x) - \int_{|v| \leq \sigma} [v(r, x + v) - v(r, x)] \pi(dv)| \leq \int_0^1 \int_{|v| \leq \sigma} |\nabla v(r, x + sv) - \nabla v(r, x)| |v| \pi(ds) \leq C|v|_{\beta} \int_{|v| \leq \sigma} |v|^{\beta} d\pi.
\]

If \(\alpha < \beta \in (2, 4], \alpha \in (1, 2]\), then for all \((r, x) \in H\),

\[
|R^{\alpha, \beta} v(r, x) - \int_{|v| \leq \sigma} [v(r, x + v) - v(r, x) - (\nabla v(r, x), v)] d\pi| \leq \int_0^1 \int_{|v| \leq \sigma} |D^2 v(r, x + sv) - D^2 v(r, x)| |v| d\pi ds \leq C|v|_{\beta} \int_{|v| \leq \sigma} |v|^{\beta \wedge 3} d\pi.
\]
The estimate of the difference $R^{\alpha,\beta} v - \bar{L} v$ in the other cases is straightforward and (4.8) follows by (4.11).

Since $Z^\sigma, \bar{Z}^\sigma$ and $R^\sigma$ are independent and $\tau, \tau'$ are $\mathbb{F}Z^\sigma$ stopping times, we have by (4.8) that

$$|E[h(Z^\sigma_{\tau'} - Z^\sigma_{\tau} + \bar{Z}^\sigma_{\tau'} - \bar{Z}^\sigma_{\tau} - R^\sigma_{\tau'} + R^\sigma_{\tau})]| \leq C\phi(\sigma)|h|_{\beta} E[|\tau' - \tau|_{\mathbb{F}_\tau}].$$

The statement follows. \qed

For the proof of Theorem 2 we will need the following estimate.

**Lemma 7.** Let

$$V_t = at + bW_t + GZ_t,$$

where $a \in \mathbb{R}^d$, $b$ is a $d \times d$-matrix and $G$ is a $m \times m$-matrix. We assume $b = 0$ if $\alpha \in (0, 2)$ and $a = 0$ if $\alpha \in (0, 1)$ and

$$|a| + |b| + |G| \leq K.$$

Let $\alpha < \beta \leq \mu \leq 2\alpha$ and $h \in \tilde{C}^{\beta-\alpha}(\mathbb{R}^d)$.

Then there is a constant $C = C(\alpha, \beta, K)$ such that

$$|E h(V_t) - h(0)| \leq C t^{\frac{\beta}{\alpha} - 1}|h|_{\beta - \alpha}.$$

**Proof.** For $f \in \tilde{C}^{\beta}(\mathbb{R}^d)$, applying Itô formula,

$$Ef(V_t) - f(0) = E \int_0^t \mathcal{K} f(V_r) dr,$$

where for $x \in \mathbb{R}^d$

$$\mathcal{K} f(x) = (a, \nabla f(x)) + \frac{1}{2} \sum_{i,j} b^* b_{ij} \partial^2 f(x)
+ \int [f(x + v) - f(x) - \chi_\alpha(v)(\nabla f(x), v)]\pi(du).$$

For $h \in \tilde{C}^{\beta-\alpha}(\mathbb{R}^d)$ we take $w \in C^\infty_0(\mathbb{R}^d)$, be a nonnegative smooth function with support in $\{|x| \leq 1\}$ such that $w(x) = w(|x|), x \in \mathbb{R}^d$, and $\int w(x) dx = 1$. For $x \in \mathbb{R}^d$ and $\varepsilon \in (0, 1)$, define $w^\varepsilon(x) = \varepsilon^{-d} w(\frac{x}{\varepsilon})$ and the convolution

$$h^\varepsilon(x) = \int f(y) w^\varepsilon(x - y) dy,$$ 

$x \in \mathbb{R}^d$.

Then by Lemma 4

$$|E h(V_t) - h(0)| \leq 2\varepsilon^{\beta-\alpha}|h|_{\beta - \alpha} + |E \int_0^t \mathcal{K} h^\varepsilon(V_r) dr|$$

$$\leq C|h|_{\beta - \alpha}(\varepsilon^{\beta - \alpha} + \varepsilon^{\beta - 2\alpha t})$$

for each $\varepsilon \in (0, 1)$. The statement follows by minimizing the inequality in $\varepsilon$. \qed
4.2.1. **Proof of Theorem 2.** Let \( u \in \tilde{C}^\beta(H) \) be the unique solution to the backward Kolmogorov equation

\[
(\partial_t + L)u(t, x) = 0,
\]
\[
u(T, x) = g(x).
\]

Let for \( \tau_i \leq t \leq \tau_{i+1} \)

\[
H^i_t = a(\tilde{Y}_{\tau_i})(t - \tau_i) + b(\tilde{Y}_{\tau_i})(W_t - W_{\tau_i}) + G(\tilde{Y}_{\tau_i})(Z_t - Z_{\tau_i})
\]

and denote \( \Delta \tilde{Y}_{\tau_i} = \tilde{Y}_{\tau_{i+1}} - \tilde{Y}_{\tau_i} \). We approximate

\[
u(T, \tilde{Y}_T) - \nu(0, Y_0) = \sum_i \nu(\tau_{i+1}, \tilde{Y}_{\tau_{i+1}}) - \nu(\tau_i, \tilde{Y}_{\tau_i})
\]

\[
= \sum_i [\nu(\tau_{i+1}, \tilde{Y}_{\tau_{i+1}} + \Delta \tilde{Y}_{\tau_i}) - \nu(\tau_{i+1}, \tilde{Y}_{\tau_{i+1}} + H^i_{\tau_{i+1}})]
\]

\[
+ \sum_i [\nu(\tau_{i+1}, \tilde{Y}_{\tau_{i+1}} + H^i_{\tau_{i+1}}) - \nu(\tau_{i}, \tilde{Y}_{\tau_i})]
\]

\[
= D_1 + \sum_i D_{2i}.
\]

According to (2.4) (Lemma 6),

\[
E|D_1| \leq C\phi(\sigma)|u|_\beta \leq C\phi(\sigma)|g|_\beta.
\]

Now, we estimate the second term. By Ito formula for each \( i \),

\[
E[D_{2i}|\mathcal{F}_{\tau_i}] = E[u(\tau_{i+1}, \tilde{Y}_{\tau_{i+1}} + H^i_{\tau_{i+1}}) - u(\tau_{i+1}, \tilde{Y}_{\tau_{i+1}})|\mathcal{F}_{\tau_i}]
\]

\[
= E\{ \int_{\tau_i}^{\tau_{i+1}} [\partial_t u(r, \tilde{Y}_{\tau_i} + H^i_{\tau_i}) + L_{\tilde{Y}_{\tau_i}} u(r, \tilde{Y}_{\tau_i} + H^i_{\tau_i})]dr \}_{\mathcal{F}_{\tau_i}} \}
\]

\[
= E\int_{\tau_i}^{\tau_{i+1}} \left[ (\partial_t u(r, \tilde{Y}_{\tau_i} + H^i_{\tau_i}) - \partial_t u(r, \tilde{Y}_{\tau_i}))
\right.
\]

\[
+ (L_{\tilde{Y}_{\tau_i}} u(r, \tilde{Y}_{\tau_i} + H^i_{\tau_i}) - L_{\tilde{Y}_{\tau_i}} u(r, \tilde{Y}_{\tau_i})) \}dr
\]

and by Theorem 4 and Lemmas 1 and 7,

\[
\left| \sum_i E D_{2i} \right| \leq \sum_i |E D_{2i}| \leq C\delta^{\frac{\beta}{\alpha} - 1}|Lu|_{\beta - \alpha}
\]

\[
\leq C\delta^{\frac{\beta}{\alpha} - 1}|u|_{\beta} \leq C\delta^{\frac{\beta}{\alpha} - 1}|g|_{\beta}
\]

and the statement of Theorem 2 follows.
4.3. Approximate jump-adapted scheme. Consider the approximation of $X_t$ defined by the increments of $\tilde{Z}_t = Z^\sigma_t + R^\sigma_t, 0 \leq t \leq T$, in Example 1. For $\sigma \in (0, 1), \delta > 0$, consider the following $Z^\sigma$-jump adapted time discretization: $\tau_0 = 0$,

$$
\tau_{i+1} = \inf \{ t > \tau_i : \Delta Z^\sigma_t \neq 0 \} \wedge (\tau_i + \delta) \wedge T.
$$

In this case the time discretization $\{\tau_i, i = 0, \ldots, n_T\}$ of the interval $[0, T]$ is random, $\tau_i$ are stopping times. We approximate $X_t$ by

$$
\hat{Y}_t = X_0 + \int_0^t a(\hat{Y}_{\tau_i}) ds + \int_0^t b(\hat{Y}_{\tau_i}) dW_s + \int_0^t G(\hat{Y}_{\tau_i}) d\hat{Z}_s, t \in [0, T].
$$

In this case,

$$
\tau_{i+1} - \tau_i = \eta_{i+1} \wedge \delta \wedge (T - \tau_i)
$$

with

$$
\eta_{i+1} = \inf(t > 0 : p((\tau_i, \tau_i + t], \{ |u| > \sigma \}) \geq 1)
$$

and $\eta_{i+1}$ is $\mathcal{F}_{\tau_i}$-conditionally exponential with parameter $\lambda_\sigma = \pi(\{ |u| > \sigma \})$.

**Lemma 8.** Let $\delta'_i = \delta \wedge (T - \tau_i), i \geq 0$, and $\lambda_\sigma = \pi(\{ |u| > \sigma \})$.

(i) There is constant $c > 0$ such that for any $i \geq 0$

$$
c (\delta'_i \wedge \lambda^{-1}_\sigma) \leq \mathbb{E}[\tau_{i+1} - \tau_i | \mathcal{F}_{\tau_i}] \leq \delta'_i \wedge \lambda^{-1}_\sigma.
$$

(ii) There is a constant $C$ such that for any $i \geq 0$,

$$
\mathbb{E}[(\tau_{i+1} - \tau_i)^2 | \mathcal{F}_{\tau_i}] \leq C \mathbb{E}[\delta^2_i \wedge \lambda^{-2}_\sigma | \mathcal{F}_{\tau_i}]
$$

$$
\leq C (\delta \wedge \lambda^{-1}_\sigma) \mathbb{E}[\tau_{i+1} - \tau_i | \mathcal{F}_{\tau_i}].
$$

**Proof.** Since $\tau_{i+1} - \tau_i = \eta_{i+1} \wedge \delta \wedge (T - \tau_i)$ and

$$
\eta_{i+1} = \inf(t > 0 : p((\tau_i, \tau_i + t], \{ |u| > \sigma \}) \geq 1)
$$

is $\mathcal{F}_{\tau_i}$-conditionally exponential with parameter $\lambda_\sigma$, we find

$$
\mathbb{E}[\tau_{i+1} - \tau_i | \mathcal{F}_{\tau_i}] = \mathbb{E}[\eta_{i+1} \wedge \delta'_i | \mathcal{F}_{\tau_i}] = \lambda_\sigma \int_0^{\delta'_i} t e^{-\lambda_\sigma t} dt + \delta'_i e^{-\lambda_\sigma \delta'_i}
$$

$$
= \frac{1 - e^{-\lambda_\sigma \delta'_i}}{\lambda_\sigma}.
$$

If $\delta'_i \geq \lambda^{-1}_\sigma$, then $\delta'_i \lambda_\sigma \geq 1$ and

$$
\frac{1 - e^{-\lambda_\sigma \delta'_i}}{\lambda_\sigma} \geq \frac{1 - e^{-1}}{\lambda_\sigma} \geq \frac{1}{3} \lambda^{-1}_\sigma.
$$

If $\delta'_i \leq \lambda^{-1}_\sigma$, then $\delta'_i \lambda_\sigma \leq 1$ and

$$
\frac{1 - e^{-\lambda_\sigma \delta'_i}}{\lambda_\sigma} \delta'_i \geq \frac{1}{2} \delta'_i.
$$
Therefore (i) follows. Similarly,
\[ E[(\tau_{i+1} - \tau_i)^2 | \mathcal{F}_{\tau_i}] = \lambda_\sigma E[\int_0^{\delta_i} t^2 e^{-\lambda_\sigma t} dt + \delta_i^2 e^{-\lambda_\sigma \delta_i} | \mathcal{F}_{\tau_i}] dt = \frac{2}{\lambda_\sigma^2} [-\lambda_\sigma \delta_i e^{-\lambda_\sigma \delta_i} + 1 - e^{-\lambda_\sigma \delta_i}] \]
and (ii) follows using (i).

An immediate consequence of Lemma 8 is the following statement.

**Corollary 5.** (i) There are constants \( c, C > 0 \) such that
\[ c \sum_i (\tau_{i+1} - \tau_i) \leq \sum_i E[(\delta \wedge \lambda_\sigma^{-1}) \wedge (T - \tau_i)] \leq CE \sum_i (\tau_{i+1} - \tau_i) = CT. \]
(ii) There is \( C > 0 \) such that
\[ \sum_i E[(\tau_{i+1} - \tau_i)^2] \leq CT(\delta \wedge \lambda_\sigma^{-1}). \]

**Proof.** We derive (i) by summing inequalities in Lemma 8(i). According to Lemma 8(ii) and (i),
\[ \sum_i E[(\tau_{i+1} - \tau_i)^2] \leq C \sum_i E[(T - \tau_i)^2 \wedge \delta^2 \wedge \lambda_\sigma^{-2}] \leq C(T \wedge \delta \wedge \lambda_\sigma^{-1}) \sum_i E[(T - \tau_i) \wedge \delta \wedge \lambda_\sigma^{-1}] \leq CT(\delta \wedge \lambda_\sigma^{-1}). \]
The statement follows.

For the proof of Theorem 3 we will need the following estimate as well.

**Lemma 9.** Let
\[ V_t = at + b W_t + G Z_t, \]
where \( a \in \mathbb{R}^d, b \) is a \( d \times d \)-matrix and \( G \) is a \( m \times m \)-matrix. We assume \( b = 0 \) if \( \alpha \in (0, 2) \) and \( a = 0 \) if \( \alpha \in (0, 1) \) and
\[ |a| + |b| + |G| \leq K. \]
Let \( \alpha < \beta \leq \mu \leq 2\alpha \) and \( h \in \tilde{C}^{\beta - \alpha}(\mathbb{R}^d) \).

Then there is a constant \( C = C(\alpha, \beta, K) \) such that for any \( i \geq 0 \)
\[ |E[\int_{\tau_i}^{\tau_{i+1}} h(V_t) - h(V_{\tau_i}) | \mathcal{F}_{\tau_i}]| \leq C|h|_{\beta - \alpha} \tilde{\lambda}_\sigma^{\frac{\beta - \alpha}{\alpha}} (\delta \wedge \lambda_\sigma^{-1})^{\frac{\beta - \alpha - 1}{\alpha}} \sum_i E[(\tau_{i+1} - \tau_i) | \mathcal{F}_{\tau_i}], \]
where \( \lambda_\sigma = \pi(\{|v| > \sigma\}) \),
\[ \tilde{\lambda}_\sigma = 1 + \mathbf{1}_{\alpha \in (1, 2)} \int_{|u| > \sigma} v d\pi. \]
Proof. For $f \in \tilde{C}^\beta(\mathbb{R}^d)$, $i \geq 0$, applying Ito formula,

$$
\mathbb{E}\left[\int_{\tau_i}^{\tau_{i+1}} f(V_r) - f(V_{\tau_i}) \mid \mathcal{F}_{\tau_i}\right] = \mathbb{E}\int_{\tau_i}^{\tau_{i+1}} Kf(V_r)dr + M_s - M_{\tau_i} |ds| \mathcal{F}_{\tau_i} dr,
$$

where for $x \in \mathbb{R}^d$,

$$
Kf(x) = (a, \nabla f(x)) + \frac{1}{2} \sum_{i,j} b^i b^j \partial_{i,j} f(x)
$$

and

$$
M_t = \int_0^t \int [f(V_r + G\nu) - f(V_{r-})]q(dr, d\nu), t \in [0, T]
$$

Note that

$$
\int_{\tau_i}^{\tau_{i+1}} (M_s - M_{\tau_i})d(s - \tau_i) = (M_{\tau_{i+1}} - M_{\tau_i})(\tau_{i+1} - \tau_i) - \int_{\tau_i}^{\tau_{i+1}} (s - \tau_i)dM_s.
$$

Since $Z^\alpha$ and $\bar{Z}^\alpha = Z - Z^\alpha$ are independent and $\tau_i$ are $\mathbb{P}^{Z^\alpha}$-stopping times, it follows by definition of $\tau_i$ that

$$
\mathbb{E}[M_{\tau_{i+1}} - M_{\tau_i}](\tau_{i+1} - \tau_i) - \int_{\tau_i}^{\tau_{i+1}} (s - \tau_i)dM_s |\mathcal{F}_{\tau_i}]
$$

$$
= \mathbb{E}[-(\tau_{i+1} - \tau_i)(U^\alpha_{\tau_{i+1}} - U^\alpha_{\tau_i}) + \int_{\tau_i}^{\tau_{i+1}} (s - \tau_i)dU^\alpha_s |\mathcal{F}_{\tau_i}],
$$

where

$$
U^\alpha_t = \int_0^t \int_{|\nu| > \sigma} [f(V_{r-} + G\nu) - f(V_{r-})]d\pi d\nu
$$

$$
= \int_0^t \int_{|\nu| > 1} [f(V_{r-} + G\nu) - f(V_{r-})]d\pi d\nu + \int_0^t \int_{1 \geq |\nu| > \sigma} \chi_\sigma(v)(\nabla f(V_r), v)d\pi d\nu
$$

Hence

$$
(4.13) \quad \mathbb{E}[\int_{\tau_i}^{\tau_{i+1}} f(V_r) - f(V_{\tau_i}) \mid \mathcal{F}_{\tau_i}] dr]
$$

$$
\leq C(1 + 1_{\alpha \in (1,2)} \int_{1 \geq |\nu| > \sigma} \nu d\pi |f|_\beta \mathbb{E}[(\tau_{i+1} - \tau_i)^2 |\mathcal{F}_{\tau_i}].
$$

For $h \in \tilde{C}^{\beta - \alpha}(\mathbb{R}^d)$ we take $w \in C_0^\infty(\mathbb{R}^d)$, be a nonnegative smooth function with support in $\{|x| \leq 1\}$ such that $w(x) = w(|x|)$, $x \in \mathbb{R}^d$, and
$f \, w(x) \, dx = 1$. For $x \in \mathbb{R}^d$ and $\varepsilon \in (0, 1)$, define $w^\varepsilon(x) = \varepsilon^{-d} w \left( \frac{x}{\varepsilon} \right)$ and the convolution

$$h^\varepsilon(x) = \int f(y) \, w^\varepsilon(x-y) \, dy, \, x \in \mathbb{R}^d.$$ 

Then by Lemma 4 and (4.13),

$$\text{Proof of Theorem 3.} \quad 4.3.1. \quad \varepsilon \text{ Minimizing the inequality in } \varepsilon \text{ we find by Lemma S(ii) that}$$

$$\left| \mathbf{E} \left[ \int_{\tau_i}^{\tau_{i+1}} h(V_t) - h(V_{\tau}) | \mathcal{F}_{\tau_i} \right] \right| \leq C |h|_{\beta-\alpha} \lambda_\sigma^{-1} \mathbf{E} [ (\tau_{i+1} - \tau_i) | \mathcal{F}_{\tau_i} ]^{\frac{\beta}{\beta-\alpha}} \mathbf{E} [ (\tau_{i+1} - \tau_i)^2 | \mathcal{F}_{\tau_i} ]^\frac{\beta}{\beta-1} \leq C |h|_{\beta-\alpha} \lambda_\sigma^{-1} (\delta \wedge \lambda_\sigma^{-1})^{\frac{\beta}{\beta-1}} \mathbf{E} [ (\tau_{i+1} - \tau_i) | \mathcal{F}_{\tau_i} ].$$ 

4.3.1. Proof of Theorem 3. Let $u \in \bar{C}^\beta(H)$ be the unique solution to the backward Kolmogorov equation (see Theorem 3)

$$4.14 \quad (\partial_t + L) u(t,x) = 0, \quad u(T,x) = g(x).$$

Let for $\tau_i \leq t \leq \tau_{i+1}$

$$H^i_t = a(\hat{Y}_{\tau_i}) (t-\tau_i) + b(\hat{Y}_{\tau_i}) (W_t - W_{\tau_i}) + G(\hat{Y}_{\tau_i}) (Z_t - Z_{\tau_i})$$

and denote $\Delta \hat{Y}_{\tau_i} = \hat{Y}_{\tau_{i+1}} - \hat{Y}_{\tau_i}$. We approximate

$$u(T, \hat{Y}_T) - u(0, X_0) = \sum_i u(\tau_{i+1}, \hat{Y}_{\tau_{i+1}}) - u(\tau_i, \hat{Y}_{\tau_i})$$

$$= \sum_i [u(\tau_{i+1}, \hat{Y}_{\tau_i} + \Delta \hat{Y}_{\tau_i}) - u(\tau_{i+1}, \hat{Y}_{\tau_i} + H^i_{\tau_{i+1}})]$$

$$+ \sum_i [u(\tau_{i+1}, \hat{Y}_{\tau_i} + H^i_{\tau_{i+1}}) - u(\tau_i, \hat{Y}_{\tau_i})] = D_1 + \sum_i D_{2i}. $$
According to Lemma \[6\]
\[
\mathbb{E}|D_1| \leq C\phi(\sigma)|u|_\beta \leq C\phi(\sigma)|g|_\beta.
\]
Now, we estimate the second term. By Ito formula for each \(i\),
\[
\mathbb{E}[D_{2i}|\mathcal{F}_{\tau_i}] = \mathbb{E}[u(\tau_{i+1}, \hat{Y}_{\tau_i} + H^i_{\tau_{i+1}}) - u(\tau_{i+1}, \hat{Y}_{\tau_i})|\mathcal{F}_{\tau_i}]
\]
\[
= \mathbb{E}\{\int_{\tau_i}^{\tau_{i+1}} [\partial_t u(r, \hat{Y}_{\tau_i} + H^i_\tau) + L_{\hat{Y}_{\tau_i}} u(r, \hat{Y}_{\tau_i} + H^i_\tau)]dr|\mathcal{F}_{\tau_i}\}
\]
\[
= \mathbb{E}\int_{\tau_i}^{\tau_{i+1}} [(\partial_t u(r, \hat{Y}_{\tau_i} + H^i_\tau) - \partial_t u(r, \hat{Y}_{\tau_i}))
+ (L_{\hat{Y}_{\tau_i}} u(r, \hat{Y}_{\tau_i} + H^i_\tau) - L_{\hat{Y}_{\tau_i}} u(r, \hat{Y}_{\tau_i})]dr
\]
and by Theorem \[4\] and Lemmas \[1, 9\] and Corollary \[5\]
\[
\left|\sum_i \mathbb{E}D_{2i}\right| \leq \sum_i |\mathbb{E}D_{2i}| \leq C\hat{\lambda}_{\sigma}^{\frac{\alpha}{2} - 1} (\delta \wedge \lambda^{-1})^{\frac{\alpha}{2} - 1} |\partial_t u|_{\beta - \omega} + |Lu|_{\beta - \omega}
\]
\[
\leq C\hat{\lambda}_{\sigma}^{\frac{\alpha}{2} - 1} (\delta \wedge \lambda^{-1})^{\frac{\alpha}{2} - 1} |u|_\beta \leq C\hat{\lambda}_{\sigma}^{\frac{\alpha}{2} - 1} (\delta \wedge \lambda^{-1})^{\frac{\alpha}{2} - 1} |g|_\beta
\]
and the statement of Theorem \[3\] follows.

5. Conclusion

The paper studies a simple weak Euler approximation of solutions to possibly completely degenerate stochastic differential equations driven by Lévy processes. The dependence of the rate of convergence on the regularity of coefficients and driving processes is investigated under the assumption of \(\beta\)-Lipschitz continuity of the coefficients. It is assumed that the SDE is driven by Levy processes of order \(\alpha \in (0, 2]\) and that the tail of the Lévy measure of the driving process has a \(\mu\)-order finite moment \((\mu \in (\alpha, 2\alpha)\). The resulting rate depends on \(\beta, \alpha\) and \(\mu\). Following \[3\], the robustness of the results to the approximation of the law of the increments of the driving noise is studied as well. It is shown that time discretization and substitution errors add up. In addition, a jump-adapted approximate Euler scheme is considered as well. The derived error estimate shows that sometimes the inclusion of jump moments into time discretization \(\{\tau_i\}\) could improve the convergence rate. In order to estimate the rate of convergence, the existence of a unique solution to the corresponding backward degenerate Kolmogorov equation in Lipshitz space is first proved.

On the other hand, there is a discrepancy in the model \[1.1\] between \(\alpha = 2\) and \(\alpha \in (0, 2]\). One would like to consider the equation
\[
X_t = X_0 + \int_0^t a(X_s)ds + \int_0^t b(X_s)dW^\alpha_s + \int_0^t G(X_{s-})dZ_s, t \in [0, T],
\]
with a possibly degenerate \(b\) and a spherically symmetric \(\alpha\)-stable \(W^\alpha\) (in \[1.1\], \(b = 0\) for \(\alpha \in (0, 2]\)).
Since \((1.1)\) could be degenerate, a solution corresponding to a given \(\alpha \in (0, 2]\) can be looked at as a solution corresponding to \(\bar{\alpha} \in (\alpha, 2]\) as well. Therefore the rate for a fixed \(\alpha\) cannot be "universally optimal": there is always a large subclass for which the rate claimed for \(\alpha\) could be better and achieved under weaker assumptions. For example, if \(\beta = \mu = 2\alpha\) with \(\alpha \in (0, 2)\) (the diffusion part is absent), the convergence order is \(\kappa = 1\) (\(\mu = 4\) and \(G \in \tilde{C}^4\) is not needed). Even "strictly at \(\alpha\)”, the assumption about the tail moment \(\mu \in (\alpha, 2\alpha]\) is not optimal. It could be weakened for a subclass with the driving processes \(Z\) such that the compensator of the jump measure of \(X\) has a nice density with respect to a reference measure. For example, let us consider the following one dimensional model

(5.1) \[X_t = X_0 + \int_0^t a(X_s)ds + \int_0^t b(X_s)dW_s + \int_0^t G(X_{s-})dZ_s, t \in [0, T],\]

where \(Z\) is a symmetric \(\lambda\)-stable with \(\lambda \in (0, 1)\) and \(G \geq 0\). Assume \(a, b, G, g \in \tilde{C}^4(\mathbb{R})\). Although \(\mu < 1\) in this case and the equation is possibly degenerate, a plausible convergence rate is still \(\kappa = 1\) (or \(\kappa = \nu/4\) if \(g \in \tilde{C}^\nu(\mathbb{R}), \nu \in (0, 4]\)), because the integral part of the generator of (5.1),

\[Iv(x) = \int [v(x + G(x)y) - v(x)] \frac{dy}{|y|^{1+\lambda}} = G(x)^\lambda \int [v(x + y) - v(x)] \frac{dy}{|y|^{1+\lambda}},\]

is differentiable without assuming much about the tail moments of the Lévy measure.
