Tutorial on the Robust Interior Point Method

Yin Tat Lee∗ Santosh S. Vempala†

August 11, 2021

Abstract

We give a short, self-contained proof of the interior point method and its robust version.

1 Introduction

Consider the primal linear program

\[
\min_{Ax = b, x \in \mathbb{R}^n_{\geq 0}} c^\top x
\]

(P)

and its dual

\[
\max_{A^\top y + s = c, s \in \mathbb{R}^n_{\geq 0}} b^\top y
\]

(D)

where \(A \in \mathbb{R}^{d \times n}\) and \(\mathbb{R}_{\geq 0} = \{x \geq 0\}\). The feasible regions for the two programs are

\[
\mathcal{P} = \{x \in \mathbb{R}^n_{\geq 0} : Ax = b\}
\]

and

\[
\mathcal{D} = \{s \in \mathbb{R}^n_{\geq 0} : A^\top y + s = c\text{ for some }y\}.
\]

We define their interiors:

\[
\mathcal{P}^\circ = \{x \in \mathbb{R}^n_{\geq 0} : Ax = b\}
\]

and

\[
\mathcal{D}^\circ = \{s \in \mathbb{R}^n_{\geq 0} : A^\top y + s = c\text{ for some }y\}.
\]

To motivate the main idea of the interior point method, we recall the optimality condition for linear programs.

Theorem 1 (Complementary Slackness). Any \(x \in \mathcal{P}\) and \(s \in \mathcal{D}\) are optimal if and only if \(x^\top s = 0\). Moreover, if both \(\mathcal{P}\) and \(\mathcal{D}\) are non-empty, there exist \(x^* \in \mathcal{P}\) and \(s^* \in \mathcal{D}\) such that \((x^*)^\top s^* = 0\) and \(x^* + s^* > 0\).

More generally, the quantity \(x^\top s\) measures the duality gap of the feasible solution:

Lemma 2 (Duality Gap). For any \(x \in \mathcal{P}\) and \(s \in \mathcal{D}\), the duality gap \(c^\top x - b^\top y = x^\top s\). In particular \(c^\top x \leq \min_{x \in \mathcal{P}} c^\top x + x^\top s\).

Proof. Using \(Ax = b\) and \(A^\top y + s = c\), we can compute the duality gap as follows

\[
c^\top x - b^\top y = c^\top x - (Ax)^\top y = c^\top x - x^\top (Ay) = x^\top s.
\]

By weak duality, we have

\[
c^\top x = b^\top y + x^\top s \leq \max_{A^\top y + s = c, s \in \mathbb{R}^n_{\geq 0}} b^\top y + x^\top s \leq \min_{x \in \mathcal{P}} c^\top x + x^\top s.
\]

The main implication of Lemma 2 is that any feasible \((x, s)\) with small \(x^\top s\) is a nearly optimal solution of the linear program. This leads us to primal-dual algorithms in which we start with a feasible primal-dual solution pair \((x, s)\) and iteratively update the solution to decrease the duality gap \(x^\top s\).

2 Interior Point Method

In this section, we discuss the classical short-step interior point method. For two vectors \(a, b\), we use \(ab\) to denote the vector with components \((ab)_i = a_ib_i\) and \(a/b\) to denote the vector with components \(a_i/b_i\). For a scalar \(t \in \mathbb{R}\), we let \(t\mathbf{1}\) denote the vector with all coordinates equal to \(t\).

**Definition 3** (Central Path). We define the central path \((x_t, s_t) \in \mathcal{P}^o \times \mathcal{D}^o\) by \(x_t s_t = t\). We say \(x_t\) is on the central path of \((\mathcal{P})\) at \(t\).

The algorithm maintains a pair \((x, s) \in \mathcal{P}^o \times \mathcal{D}^o\) and a scalar \(t > 0\) satisfying the invariant

\[
\|\frac{x s}{t} - 1\|_2 \leq \frac{1}{4}.
\]

Note that the deviation from the central path is measured in \(\ell_2\) norm. In each step, the algorithm decreases \(t\) by a factor of \(1 - \Omega(n^{-1/2})\) while maintaining the invariant.

2.1 Basic Property of a Step

To see why there is a pair \((x, s) \in \mathcal{P}^o \times \mathcal{D}^o\) satisfying the invariant, we prove the following generalization.

**Lemma 4** (Quadrant Representation of Primal-Dual). Suppose \(\mathcal{P}\) is non-empty and bounded. For any positive vector \(\mu \in \mathbb{R}^n_{>0}\), there is an unique pair \((x_\mu, s_\mu) \in \mathcal{P}^o \times \mathcal{D}^o\) such that \(x_\mu s_\mu = \mu\). Furthermore, \(x_\mu = \min_{x \in \mathcal{P}} f_\mu(x)\) where

\[
f_\mu(x) = c^\top x - \sum_{i=1}^n \mu_i \ln x_i.
\]

**Proof.** Fix \(\mu \in \mathbb{R}^n_{>0}\). We define \(x_\mu = \arg\min_{x \in \mathcal{P}} f_\mu(x)\) and prove that \((x_\mu, s_\mu) \in \mathcal{P}^o \times \mathcal{D}^o\) with \(x_\mu s_\mu = \mu\) for some \(s_\mu\). Since \(\mathcal{P}\) is non-empty and bounded and since \(f_\mu\) is strictly convex, such an \(x_\mu\) exists. Furthermore, since \(f_\mu(x) \to +\infty\) as \(x_i \to 0\) for any \(i\), we have that \(x_\mu \in \mathcal{P}^o\).

By the KKT optimality condition for \(f_\mu\), there is a vector \(y\) such that

\[
\nabla f_\mu(x) = c - \frac{\mu}{x} = A^\top y.
\]

Define \(s_\mu = \frac{\mu}{x_\mu}\), then one can check that \(s_\mu \in \mathcal{D}^o\) and \(x_\mu s_\mu = \mu\).

For the uniqueness, if \((x, s) \in \mathcal{P}^o \times \mathcal{D}^o\) and \(xs = \mu\), then \(x\) satisfies the optimality condition for \(f_\mu\). Since \(f_\mu\) is strictly convex, such \(x\) must be unique. \(\Box\)

Lemma 4 shows that any point in \(\mathcal{P}^o \times \mathcal{D}^o\) is uniquely represented by a positive vector \(\mu\). Interior point methods move \(\mu\) uniformly to \(0\) while maintaining the corresponding \(x_\mu\). Now we discuss how to find \((x_\mu, s_\mu)\) given a nearby interior feasible point \((x, s)\). Namely, how to move \((x, s)\) to \((x + \delta x, s + \delta s)\) such that it satisfies the equation

\[
(x + \delta x)(s + \delta s) = \mu,
\]

\[
A(x + \delta x) = b,
\]

\[
A^\top (y + \delta y) + (s + \delta s) = c,
\]

\[
(x + \delta x, s + \delta s) \in \mathbb{R}^n_{>0}.
\]

Although the equation above involves \(y\), our approximate solution does not need to know \(y\). By ignoring the inequality constraint and the second-order term \(\delta x \delta s\) in the first equation above, and using \(Ax = b\) and \(A^\top y + s = c\) we can simplify the system:

\[
xs + S\delta x + X\delta s = \mu,
\]

\[
A\delta x = 0,
\]

\[
A^\top \delta y + \delta s = 0,
\]

where \(X\) and \(S\) are the diagonal matrix with diagonal \(x\) and \(s\). In the following Lemma, we show how to write the step above using a projection matrix \((\mathcal{P}^2 = \mathcal{P})\).
Lemma 5. Suppose that $A$ has full row rank and $(x,s) \in \mathcal{P}^0 \times \mathcal{D}^0$. Then, the unique solution for the linear system (2.1) is given by

$$
X^{-1} \delta_x = (I - P)(\delta_\mu / \mu), \\
S^{-1} \delta_s = P(\delta_\mu / \mu)
$$

where $\delta_\mu = \mu - xs$ and $P = S^{-1} A^T (AS^{-1} XA^T)^{-1} AX$.

Proof. Note that the step satisfies $S \delta_x + X \delta_s = \delta_\mu$. Multiply both sides by $AS^{-1}$ and using $A \delta_x = 0$, we have

$$
AS^{-1} X \delta_s = AS^{-1} \delta_\mu.
$$

Now we use that $A^T \delta_y + \delta_s = 0$ and get

$$
AS^{-1} XA^T \delta_y = -AS^{-1} \delta_\mu.
$$

Since $A \in \mathbb{R}^{d \times n}$ has full row rank and $S^{-1} X$ is invertible, we have that $AS^{-1} X A^T$ is invertible. Hence,

$$
\delta_y = - (AS^{-1} X A^T)^{-1} AS^{-1} \delta_\mu \quad \text{and} \quad \delta_s = A^T (AS^{-1} X A^T)^{-1} AS^{-1} \delta_\mu.
$$

Putting this into $S \delta_x + X \delta_s = \delta_\mu$, we have

$$
\delta_x = S^{-1} \delta_\mu - S^{-1} X A^T (AS^{-1} X A^T)^{-1} AS^{-1} \delta_\mu.
$$

The result follows from the definition of $P$. \hfill \Box

2.2 Lower Bounding Step Size

The efficiency of interior point methods depends on how large a step we can take while staying within the domain. We first study the step operators $(I - P)$ and $P$. The following lemma implies that $P$ is a nearly orthogonal projection matrix when $\mu$ is close to a multiple of the all-ones vector. Hence, the relative changes of $X^{-1} \delta_x$ and $S^{-1} \delta_s$ are essentially the orthogonal decomposition of the relative step $\delta_\mu / \mu$. For two vectors $u,v$, we define 

$$
\|u\|_v \overset{\text{def}}{=} \sqrt{u^T \text{Diag}(v) u}
$$

to be the norm defined by $v$.

Lemma 6. Under the assumption in Lemma 5, $P$ is a projection matrix such that $\|Pv\|_\mu \leq \|v\|_\mu$ for any $v \in \mathbb{R}^n$. Similarly, we have that $\|(I - P)v\|_\mu \leq \|v\|_\mu$.

Proof. $P$ is a projection because $P^2 = P$. Define the orthogonal projection matrix

$$
P_{\text{orth}} = S^{-1/2} X^{1/2} A^T (AS^{-1} X A^T)^{-1} AX^{1/2} S^{-1/2},
$$

then we have

$$
\|Pv\|^2_\mu = v^T X A^T (AS^{-1} X A^T)^{-1} AS^{-1} X S S^{-1} A^T (AS^{-1} X A^T)^{-1} A X v
$$

$$
= v^T S^{1/2} X^{1/2} P_{\text{orth}} S^{1/2} X^{1/2} v
$$

$$
\leq v^T S^{1/2} X^{1/2} S^{1/2} X^{1/2} v = \|v\|^2_\mu.
$$

The calculation for $\|(I - P)v\|_\mu$ is similar. \hfill \Box

Next we give a lower bound on the largest feasible step size.

Lemma 7. We have that $\|X^{-1} \delta_x\|_2^2 \leq \frac{1}{\min_i \mu_i} \|\delta_\mu / \mu\|_2^2$ and $\|S^{-1} \delta_s\|_2^2 \leq \frac{1}{\min_i \mu_i} \|\delta_\mu / \mu\|_2^2$. In particular, if $\|\delta_\mu / \mu\|_2^2 < \min_i \mu_i$, we have $(x + \delta_x, s + \delta_s) \in \mathcal{P}_0 \times \mathcal{D}_0$.

Proof. For $\|X^{-1} \delta_x\|_\infty$, we have $\min_i \mu_i \|X^{-1} \delta_x\|_\mu^2 \leq \|X^{-1} \delta_x\|_\mu^2$ and hence

$$
\|X^{-1} \delta_x\|^2_\mu \leq \frac{1}{\min_i \mu_i} \|X^{-1} \delta_x\|_\mu^2 = \frac{1}{\min_i \mu_i} \|(I - P)(\delta_\mu / \mu)\|_\mu^2 \leq \frac{1}{\min_i \mu_i} \|\delta_\mu / \mu\|_\mu^2.
$$

The proof for $\|S^{-1} \delta_s\|_\infty$ is similar.

Hence, if $\|\delta_\mu / \mu\|_2^2 < \min_i \mu_i$, we have that $\|X^{-1} \delta_x\|_\infty < 1$ and $\|S^{-1} \delta_s\|_\infty < 1$, i.e., $|\delta_{x,i}| < |x_i|$ and $|\delta_{s,i}| < |s_i|$ for all $i$. Therefore, $x + \delta_x > 0$ and $s + \delta_s > 0$ are feasible. \hfill \Box
To decrease \( \mu \) uniformly, we set \( \delta_\mu = -h \mu \) for some step size \( h \). To ensure the feasibility, we need \( \|\delta_\mu/\mu\|_\mu^2 \leq \min_i \mu_i \) and this gives the maximum step size

\[
h = \sqrt{\frac{\min_i \mu_i}{\sum_i \mu_i}} \tag{2.2}
\]

Note that the above quantity is maximized at \( h = n^{-1/2} \) when \( \mu \) has all equal coordinates.

### 2.3 Staying within small \( \ell_2 \) distance

Since the step size (2.2) maximizes when \( \mu \) is a constant vector. A natural approach is to keep \( \mu \) as a vector close in \( \ell_2 \) norm to a multiple of the all-ones vector. This motivates the following algorithm:

**Algorithm 1:** \texttt{L2Step}(A, x, s, \( t_{\text{start}} \), \( t_{\text{end}} \))

- **Define** \( P_{x,s} = S^{-1}A^\top(AS^{-1}A^\top)^{-1}AX \).
- **Invariant:** \((x, s) \in \mathcal{P}^o \times \mathcal{D}^o \) and \( \|xs - t\|_2 \leq \frac{t}{4} \).
- Let \( t = t_{\text{start}} \), \( h = 1/(16\sqrt{n}) \) and \( n \) is the number of columns in \( A \).
- **repeat**
  - Let \( t' = \max(t/(1 + h), t_{\text{end}}) \).
  - Let \( \mu = xs \) and \( \delta_\mu = t' - \mu \).
  - Let \( \delta_x = X(I - P_{x,s})(\delta_\mu/\mu) \) and \( \delta_s = SP_{x,s}(\delta_\mu/\mu) \).
  - Set \( x \leftarrow x + \delta_x \), \( s \leftarrow s + \delta_s \) and \( t \leftarrow t' \).
- **until** \( t \neq t_{\text{end}} \):
- **Return** \((x, s)\).

Note that the algorithm requires some initial point \((x, s)\) close to the central path and we will show how to get this in the next section (by changing the linear program temporarily).

First, we show that the invariant is maintained in each step. The conclusion distance less than \( t/6 \) is needed in Section A where we call \texttt{L2Step} on a modified LP, then prove the result is close to central path for the original LP.

**Lemma 8.** Suppose that the input satisfies \((x, s) \in \mathcal{P}^o \times \mathcal{D}^o \) and \( \|xs - t\|_2 \leq \frac{t_{\text{max}}}{4} \). Then, the algorithm \texttt{L2Step} maintains \((x, s) \in \mathcal{P}^o \times \mathcal{D}^o \) and \( t > 0 \) such that \( \|xs - t\|_2 \leq \frac{t}{6} \).

**Proof.** We prove by induction that \( \|xs - t\|_2 \leq \frac{t}{6} \) after each step. Note that the input satisfies \( \|xs - t\|_2 \leq \frac{t}{4} \).

Let \( x' = x + \delta_x, s' = s + \delta_s \) and \( t' \) defined in the algorithm. Note that

\[
x's' - t' = (x + \delta_x)(s + \delta_s) - t' = \mu + S\delta_x + X\delta_s + \delta_\mu \delta_s - t'.
\]

Lemma 5 shows that \( S\delta_x + X\delta_s = t' - \mu \). Hence, we have

\[
x's' - t' = \delta_\mu \delta_s = X^{-1}\delta_x \cdot S^{-1}\delta_s \cdot \mu.
\]

Using this, we have

\[
\|x's' - t'\|_2 \leq \|\mu^{1/2}X^{-1}\delta_x\|_2\|\mu^{1/2}S^{-1}\delta_s\|_2 = \|X^{-1}\delta_x\|_\mu\|S^{-1}\delta_s\|_\mu \leq \|\delta_\mu/\mu\|_\mu^2.
\]

where we used Lemma 6 at the end.

Using \( t' - \mu = \frac{t}{4}(t - \mu) + (\frac{t}{4} - 1)\mu \), we have

\[
\|\delta_\mu/\mu\|_\mu = \frac{t' t - \mu}{t} + \frac{(t' - 1)}{t} \|xs - t\|_\mu \leq \frac{t'}{t} \|xs - t\|_\mu + \frac{t'}{t} - 1\|\mu\|_\mu.
\]

Since \( \|\mu - t\|_2 \leq \frac{t}{4} \), we have \( \min_i \mu_i \geq \frac{3t}{4} \) and \( \max_i \mu_i \leq \frac{5t}{4} \). Using \( \frac{t}{4} - 1 \leq h = \frac{1}{16\sqrt{n}} \), we have

\[
\|\delta_\mu/\mu\|_\mu \leq \frac{t'}{t} \sqrt{\frac{4}{3t}} \|xs - t\|_2 + h \sqrt{\frac{5}{4}tn} \leq \sqrt{\frac{t}{12}} + h \sqrt{\frac{5}{4}tn} \leq 0.38 \sqrt{t}.
\]

Hence, we have \( \|x's' - t'\|_2 \leq \|\delta_\mu/\mu\|_\mu^2 \leq 0.15t \leq t' / 6 \). Furthermore, \( \|\delta_\mu/\mu\|_\mu^2 < \min_i \mu_i \) which implies \((x, s)\) is feasible (Lemma 7).

Note that the lemma above only concludes the output is close to central path. To upper bound the error, we can apply Lemma 2 which shows the duality gap is equal to \( x^\top s \).
2.4 Solving LP Approximately and Exactly

Here we discuss how to get a feasible interior point close to the central path by modifying the linear program. The runtime of interior point method depends on how degenerate the linear program is.

Definition 9. We define the following parameters for the linear program $\min_{x \geq 0} c^T x$:

1. Inner radius $r$: There exists a $x \in \mathcal{P}$ such that $x_i \geq r$ for all $i \in [n]$.
2. Outer radius $R$: For any $x \geq 0$ with $Ax = b$, we have that $\|x\|_2 \leq R$.
3. Lipschitz constant $L$: $\|c\|_2 \leq L$.

Since L2Step requires a feasible point near the central path, we modify the linear program to make it happen. To satisfy the constraint $Ax = b$, we start the algorithm by taking a least square solution of the constraint $Ax = \tilde{b}$. Since it can be negative, we write the variable $x = x^+ - x^-$ with both $x^+, x^- \geq 0$. We put a large cost vector on $x^-$ to ensure the solution is roughly the same. The crux of the proof is that if we optimize this new program well due to technical reasons, we need to put an extra constraint $1^T x^+ \leq \Lambda$ for some $\Lambda$ to ensure the problem is bounded. The precise formulation of the modified linear program is as follows:

Definition 10 (Modified Linear Program). Consider a linear program $\min_{x \geq 0} c^T x$ with inner radius $r$, outer radius $R$ and Lipschitz constant $L$. For any $R \geq 10R, t \geq 8L\tilde{R}$, we define the modified primal linear program by

$$\min_{(x^+, x^-, x^0) \in \mathcal{P}_{\pi}, c} \quad c^T x^+ + \tilde{c}^T x^-$$

where

$$\mathcal{P}_{\pi, t} = \{(x^+, x^-, x^0) \in \mathbb{R}^{n+1} : A(x^+ - x^-) = b, \sum_{i=1}^n x^+_i + x^0 = \tilde{b} \}$$

with $x^+_i = \frac{1}{c_i + t R}, x^-_i = x_i - A_i^T (A A)^{-1} b, \tilde{c} = t/x^-_i, \tilde{b} = \sum_i x^+_i + \tilde{R}$. We define the corresponding dual polytope

$$\mathcal{D}_{\pi, t} = \{(s^+, s^-, s^0) \in \mathbb{R}^{n+1} : A^T y + \Lambda_1 + s^+ = c, -A^T y + s^- = \tilde{c}, \lambda + s^0 = 0 \text{ for some } y \in \mathbb{R}^d \text{ and } \lambda \in \mathbb{R} \}.$$

The main result about the modified program is the following.

Theorem 11. Given a linear program $\min_{x \geq 0} c^T x$ with inner radius $r$, outer radius $R$ and Lipschitz constant $L$. For any $0 \leq \epsilon \leq \frac{1}{2}$, the modified linear program (Definition 10) with $\tilde{R} = \frac{2}{L} R, t = 216 \epsilon^{-3} n^2 \frac{R}{\pi} \cdot LR$ has the following properties:

- The point $(x^+_i, x^-_i, \tilde{R})$ is on the central path of the modified program at $t$.
- For any primal $x \equiv (x^+, x^-, x^0) \in \mathcal{P}_{\pi, t}$ and dual $s \equiv (s^+, s^-, s^0) \in \mathcal{D}_{\pi, t}$ such that $\frac{5}{6} LR \leq x_i s_i \leq \frac{7}{6} LR$, we have that
  $$(x^+ - x^-, s^+ - s^0) \in \mathcal{P} \times \mathcal{D}$$
  and that $x^+_i \leq \epsilon x^-_i$ and $s^0 \leq s^0_i$ for all $i$.

Proof. Since the proof is not illuminating, we defer it to Appendix A (Lemma 26 and Lemma 32).

Now we state our main algorithm.

Algorithm 2: SlowSolveLP($A, b, c, x^{(0)}, \delta$)

Assumption: the linear program has inner radius $r$, outer radius $R$ and Lipschitz constant $L$.

Let $\epsilon = 1/(100\sqrt{\pi}), \tilde{R} = \frac{2}{L} R, t = 216 \epsilon^{-3} n^2 \frac{R}{\pi} \cdot LR$.

// Define the modified program $\min_{x \geq 0} c^T x$ by Definition 10 with parameters $\tilde{R}$ and $t$.

Let $\bar{A} = \begin{bmatrix} A & -A \\ \bar{1} & 0 \end{bmatrix}$, $\bar{c} = (c, \tilde{c}), \bar{b} = (b, \tilde{b})$ where $\tilde{c}$ and $\tilde{b}$ are defined in Definition 10.

// Write down the central path at $t$ for modified linear program using Lemma 26.

$\bar{x} = 1/2 (\bar{x}^+ - x^- - \tilde{R}). \bar{x} = x/t$.

$(\bar{x}, \bar{z}) = L2Step(\bar{A}, \bar{x}, \bar{z}, t, LR)$.

$(x, s) = (x^+ - x^-, s^+ - s^0)$ where $\bar{x} = (x^+, x^-, x^0)$ and $\bar{z} = (s^+, s^-, s^0)$.

$(x_{end}, s_{end}) = L2Step(A, x^+ - x^-, s^+ - s^0, LR, t_{end})$ with $t_{end} = \delta LR/(2n)$.

Return $x_{end}$. 

5
Theorem 12. Consider a linear program \( \min_{A x = b, x \geq 0} c^\top x \) with \( n \) variables and \( d \) constraints. Assume the linear program has inner radius \( r \), outer radius \( R \) and Lipschitz constant \( L \) (see Definition 9). Then, \( \text{SlowSolveLP} \) outputs \( x \) such that

\[
c^\top x \leq \min_{A x = b, x \geq 0} c^\top x + \delta LR,
\]

\[
A x = b,
\]

\[
x \geq 0.
\]

The algorithm takes \( O(\sqrt{n} \log(nR/\delta r)) \) Newton steps (defined in (2.1)).

If we further assume that the solution \( x^* = \arg \min_{A x = b, x \geq 0} c^\top x \) is unique and that \( c^\top x \geq c^\top x^* + \eta LR \) for any other vertex \( x \) of \( \{ A x = b, x \geq 0 \} \) for some \( \eta \geq \delta \geq 0 \), then we have that \( \| x - x^* \|_2 \leq \frac{2\delta R}{\eta} \).

Proof. By Theorem 11, the point \( (x^+_c, x^-_c, R) \) is on the central path of the modified program at \( t \). After the first call of \( \text{L2Step} \), Lemma 8 shows that \( \text{L2Step} \) returns \( (\overline{x}, \overline{s}) \) such that \( \| x - \overline{x} \|_2 \leq \frac{1}{6} \) with \( t = LR \).

Theorem 11 shows that \( (x, s) = (x^+ - x^-, s^+ - s^-) \in \mathcal{P} \times D \) and that \( x = (1 + \epsilon)x^+ \) and \( s = (1 + \epsilon)s^- \). Since \( \epsilon = \frac{1}{100nR} \) and \( \| x^+ s^+ - t \|_2 \leq \frac{1}{6} \) with \( t = LR \), we have that \( \| x s - t \|_2 \leq \frac{1}{6} \). This verifies the condition for the second call of \( \text{L2Step} \).

After the second call of \( \text{L2Step} \), Lemma 8 shows that \( \text{L2Step} \) returns \( (x_{\text{end}}, s_{\text{end}}) \) such that \( \| x_{\text{end}} s_{\text{end}} - t_{\text{end}} \|_2 \leq \frac{1}{6} \) with \( t_{\text{end}} = \delta LR/(2n) \). Hence, Lemma 2 shows that

\[
c^\top x_{\text{end}} \leq \min_{A x = b, x \geq 0} c^\top x + x_{\text{end}} s_{\text{end}} \leq \min_{A x = b, x \geq 0} c^\top x + t_{\text{end}} n \leq \min_{A x = b, x \geq 0} c^\top x + \delta LR.
\]

For the runtime, note that \( \text{L2Step} \) decreases \( t \) by \( 1 - \Omega(n^{-1/2}) \) factor each step. Hence, the first call takes \( O(\sqrt{n} \log(nR/\delta r)) \) Newton steps and second call takes \( O(\sqrt{n} \log(n/\delta)) \) Newton steps.

For the last conclusion, we assume \( \delta \leq \eta \) and let \( \mathcal{P}_\eta = \mathcal{P} \cap \{ c^\top x \leq c^\top x^* + t LR \} \). Note that \( \mathcal{P}_\eta \) is a cone at \( x^* \) (because there is no vertex except \( x^* \) with value less than \( c^\top x^* + t LR \)). Hence, we have \( \mathcal{P}_\delta - x^* = \frac{\delta}{\eta}(\mathcal{P}_\eta - x^*) \).

Since \( x \in \mathcal{P}_\delta \), we have that

\[
\| x - x^* \|_2 \leq \frac{\delta}{\eta} \text{diameter}(\mathcal{P}_\eta - x^*) \leq \frac{2\delta R}{\eta}.
\]

Exercise 13. Make the perturbation deterministic while preserving solutions.

3 Robust Interior Point Method

To improve the interior point method, one can either improve the number of steps \( \tilde{O}(\sqrt{n}) \) or the cost per step. The first is a major open problem. In this note, we focus on the latter question. Recall from (2.1) that the linear system we solve in each step is of the form

\[
S \delta_x + X \delta_s = \delta, \quad A \delta_x = 0, \quad A^\top \delta_y + \delta_s = 0.
\]

In each step, \( x, s \) and \( \delta_x \) in the equation above changes relatively by a vector with bounded \( \ell_2 \) norm. So, only few coordinates change a lot in each step. To take advantage of this, the robust interior point method contains two new components: 1) Analyze the convergence when we only solve the linear system approximately (Section 3.1). 2) Show how to maintain the solution throughout the iteration (Section 3.2 and Section 3.3).
3.1 Staying within small \( \ell_\infty \) distance

In the above description and analysis, we assumed that we computed each step of the interior point method precisely. But one can imagine that it suffices to compute steps approximately since our goal is only to stay close to the central path. This could have significant computational advantages.

To make the interior point method robust to noise in the updates to \( x \) and \( s \), we need the method to work under a larger neighborhood than that given by the Euclidean norm (\( \|xs - t\|_2 \leq 4t \)). We cannot increase the radius of the \( \ell_2 \) ball because we need the neighborhood to lie strictly inside the feasible region. One natural alternative choice of distance and potential would be a higher norm, \( \|xs - t\|_q \). However, analyzing the step \( \delta_\mu \) that minimizes \( \|\mu + \delta_\mu - t\|_q^q \) involves many cases. Instead, we use the potential

\[
\Phi(r) = \sum_{i=1}^{n} \cosh(\lambda r_i) = \sum_{i=1}^{n} \frac{e^{\lambda r_i} + e^{-\lambda r_i}}{2}.
\]

with \( r = \frac{x - t}{t} \) for some scalar \( \lambda = \Theta(\log n) \). This potential induces the following algorithm where each step of the algorithm takes the step \( \delta_\mu \approx -\nabla \Phi(\frac{x - t}{t}) \).

**Algorithm 3: RobustStep(\( A, x, s, t_{\text{start}}, t_{\text{end}} \))**

1. Define \( \Phi(r) \) and \( r \) according to (3.2) with \( \lambda = 16 \log 40n \).
2. **Invariant:** \( (x, s) \in \mathcal{P}^o \times \mathcal{D}^o \) and \( \Phi(r) \leq 16n \).
3. Let \( t = t_{\text{start}}, h = 1/(128\lambda \sqrt{n}) \) and \( n \) is the number of columns in \( A \).
4. repeat
   1. Pick \( x, x, s, s \) such that \( \|\ln x - \ln x\|_\infty \leq \frac{1}{48}, \|\ln s - \ln s\|_\infty \leq \frac{1}{48} \) and \( \|\tau - r\|_\infty \leq \frac{1}{48\lambda} \).
   2. Let \( t' = \max(t/(1 + h), t_{\text{end}}) \), \( \delta_\mu = -\frac{t'}{32\lambda} \frac{\overline{r}}{\|\overline{r}\|_2}, \overline{g} = \nabla \Phi(\overline{r}) \).
   3. Find \( \delta_x, \delta_s \) such that
      \[
      \begin{align*}
      \mathbb{S}\delta_x + X\delta_s &= \delta_\mu, \\
      A\delta_x &= 0, \\
      A^T\delta_y + \delta_s &= 0.
      \end{align*}
      \]
5. Set \( x \leftarrow x + \delta_x, s \leftarrow s + \delta_s \) and \( t \leftarrow t' \).
6. until \( t \neq t_{\text{end}} \);
7. Return \( (x, s) \).

We begin with useful facts about \( \Phi \).

**Lemma 14.** Define \( \Phi(r) \) according to (3.2). For any \( r \in \mathbb{R}^n \), we have that \( \|r\|_\infty \leq \frac{\log 2\Phi(r)}{\lambda} \) and \( \|\nabla \Phi(r)\|_2 \geq \ldots \)
\( \frac{1}{\sqrt{n}} (\Phi(r) - n) \). Moreover, if \( \Phi(r) \geq 4n \) and \( \|\delta\|_{\infty} \leq \frac{1}{16\lambda} \), we have

\[
\|\nabla \Phi(r + \delta) - \nabla \Phi(r)\|_2 \leq \frac{1}{3} \|\nabla \Phi(r)\|_2.
\]

**Proof.** We have \( \Phi(r) \geq \frac{1}{2} \min_{i} e^{\lambda r_{i}} \) and hence \( \|r\|_{\infty} \leq \frac{\log 2^{\Phi(r)}}{\lambda} \).

For the second claim, using that \( \nabla \Phi(r) = \sum_{i=1}^{n} \lambda \sinh(\lambda r_{i}) \), we have

\[
\|\nabla \Phi(r)\|_2 = \lambda \left( \sum_{i=1}^{n} \sinh^2(\lambda r_{i}) \right) = \lambda \left( \sum_{i=1}^{n} (\cosh^2(\lambda r_{i}) - 1) \right)
\]

\[
\geq \frac{\lambda}{\sqrt{n}} \sum_{i=1}^{n} \cosh^2(\lambda r_{i}) - 1 \geq \frac{\lambda}{\sqrt{n}} \sum_{i=1}^{n} (\cosh(\lambda r_{i}) - 1)
\]

\[
= \frac{\lambda}{\sqrt{n}} (\Phi(r) - n).
\]

For the last claim, using \( \sinh(r + \delta) = \sinh r \cosh \delta + \cosh r \sinh \delta \) and \( |\cosh r - \sinh r| \leq 1 \), for \( |\delta| \leq \frac{1}{6} \), we have

\[
|\sinh(r + \delta) - \sinh(r)| \leq |\cosh \delta - 1| \cdot |\sinh r| + |\sinh \delta| \cdot |\cosh r|
\]

\[
\leq (|\cosh \delta - 1| + |\sinh \delta|) \cdot |\sinh r| + |\sinh \delta| \leq \frac{1}{4} |\sinh r| + \frac{1}{4}.
\]

Using that \( \nabla \Phi(r) = \sum_{i=1}^{n} \lambda \sinh(\lambda r_{i}) \), for \( \|\delta\|_{\infty} \leq \frac{1}{16\lambda} \), we have

\[
\|\nabla \Phi(r + \delta) - \nabla \Phi(r)\|_2 \leq \frac{1}{4} \|\nabla \Phi(r)\|_2 + \frac{\sqrt{n} \lambda}{4}.
\]

Since \( \Phi(r) \geq 4n \), we have that \( \|\nabla \Phi(r)\|_2 \geq 3\sqrt{n} \lambda \) and hence (3.4) shows that

\[
\|\nabla \Phi(r + \delta) - \nabla \Phi(r)\|_2 \leq \left( \frac{1}{4} + \frac{1}{12} \right) \|\nabla \Phi(r)\|_2 = \frac{1}{3} \|\nabla \Phi(r)\|_2.
\]

We collect some basic bounds on the step in the following lemma.

**Lemma 15.** Using the notation in RobustStep (Algorithm 3). Under the invariant \( \Phi((x - t)/t) \leq 16n \), we have \( \|x - t\|_{\infty} \leq \frac{t}{16}, \|\delta_{x}/x\|_{2} \leq \frac{1}{16\lambda}, \text{ and } \|\delta_{s}/s\|_{2} \leq \frac{1}{16\lambda} \).

**Proof.** Using \( \Phi((x - t)/t) \leq 16n \) and Lemma 14, we have

\[
\|x - t\|_{\infty} \leq \frac{t \log 32n}{\lambda} \leq \frac{t}{16}
\]

By Lemma 5, we have \( X^{-1} \delta_{x} = (I - P) (\delta_{\mu}/\mu) \) where \( \overline{\mu} = \overline{x}s \) and \( P = S^{-1} A^\top (A S^{-1} A A^\top)^{-1} A X \).

By Lemma 6, we have

\[
\|\delta_{x}/x\|_{2} = \| (I - P)^{t} \|_{\overline{x}} \| \delta_{\mu}/\mu \|_{\overline{x}}.
\]

Using that \( \|x - t\|_{\infty} \leq \frac{t}{16}, \|\ln x - \ln t\|_{\infty} \leq \frac{t}{48} \), \( \|\ln s - \ln t\|_{\infty} \leq \frac{1}{48} \), we have \( \overline{\mu} \geq \frac{10}{11} t \) and hence

\[
\|\delta_{x}/x\|_{2} \leq \sqrt{\frac{11}{10t}} \|\delta_{x}/x\|_{\overline{x}} \leq \sqrt{\frac{11}{10t}} \|\delta_{\mu}/\mu\|_{\overline{x}} \leq \frac{11}{10t} \|\delta_{\mu}\|_{2}
\]

Using the formula \( 3_{\mu} = -\frac{t'}{32\lambda} \|s_{\mu}\|_{2} \), we have

\[
\|\delta_{x}/x\|_{2} \leq \frac{11}{10} \frac{t'}{32\lambda} \leq \frac{1}{16\lambda}.
\]

Same proof gives \( \|\delta_{s}/s\|_{2} \leq \frac{1}{16\lambda} \).
Using this, we prove the algorithm RobustStep satisfies the invariant on the distance.

**Lemma 16.** Suppose that the input satisfies \((x, s) \in D^o \times D^o\) and \(\Phi((x s - t_{\text{start}})/t_{\text{start}}) \leq 16 n\). Let \(x^{(k)}, s^{(k)}, t^{(k)}\) be the \(x, s, t\) computed in the RobustStep after the \(k\)-th step. Let \(\Phi(k) = \Phi((x^{(k)} s^{(k)} - t^{(k)})/t^{(k)})\). Then, we have

\[
\Phi^{(k+1)} \leq \begin{cases} 
12 n & \text{if } \Phi^{(k)} \leq 8 n \\
\Phi^{(k)} & \text{otherwise}
\end{cases}
\]

Furthermore, we have that \(\|r^{(k+1)} - r^{(k)}\|_2 \leq \frac{1}{16 \lambda}\) where \(r^{(k)} = (x^{(k)} s^{(k)} - t^{(k)})/t^{(k)}\).

**Proof.** Fix some iteration \(k\). Let \(x = x^{(k)}, s = s^{(k)}, t = t^{(k)}, x' = x^{(k+1)}, s' = s^{(k+1)}\) and \(t' = t^{(k+1)}\). We define \(r = (x s - t)/t\) and \(r' = (x' s' - t')/t'\). By the definition of \(\delta_s\) and \(\delta_s\), we have \(\mathbf{S} \delta_x + \mathbf{X} \delta_s = \delta_x = -\frac{r'}{t'}\) and hence

\[
\frac{x s' - t'}{t'} = \frac{(x + \delta_x)(s + \delta_s) - t'}{t'} = x s + s \delta_x + x \delta_s + \delta_x \delta_s - t'
\]

\[
= x s - t + \frac{1}{32 \lambda} \frac{g}{\|g\|_2} + \eta
\]

where the error term
\[
\eta = \left(\frac{t'}{t} - 1\right) \frac{x s}{t} + \frac{(s - \pi) \delta_x + (x - \pi) \delta_s + \delta_x \delta_s}{t'}
\]

Now, we bound the error term \(\eta\). Using Lemma 15 \((\|\delta_x/x\|_2 \leq \frac{1}{16 \lambda}, \|\delta_s/s\|_2 \leq \frac{1}{16 \lambda}, \|xs - t\|_{\infty} \leq \frac{t}{16})\) and the definition of the algorithm \((\lambda \geq 16, |t' - t| \leq \frac{t}{128 \sqrt{\lambda}} \leq \frac{t}{128 \lambda^{\sqrt{\lambda}}}, \|\ln \pi - \ln x\|_{\infty} \leq \frac{1}{4}, \|\ln \pi - \ln s\|_{\infty} \leq \frac{1}{48})\), we have

\[
\|\eta\|_2 \leq \left|\frac{t'}{t} - 1\right| x s + \frac{2}{128 \lambda} \left(x s - t\right) + \frac{s - \pi}{s} \frac{x}{s} \delta_x \xrightarrow{\infty} \|\delta_x\|_2 + \frac{\|xs - t\|_{\infty}}{\lambda} \leq \frac{1}{128 \lambda} \left(17 + 9 \left(e^{1/48} - 1\right)\right)
\]

In particular, we use (3.5) and (3.6) to get

\[
\|r - r'\|_2 \leq \frac{1}{32 \lambda} + \|\eta\|_2 \leq \frac{1}{16 \lambda}.
\]

This proves the conclusion about \(r\).

Case 1: \(\Phi(r) \leq 8 n\).

The definition of \(\Phi\) together with the fact \(\|r - r'\|_2 \leq \frac{1}{16 \lambda}\) implies that \(\Phi(r') \leq \frac{3}{2} \Phi(r) \leq 12 n\).

Case 2: \(\Phi(r) \geq 8 n\).

Mean value theorem shows there is \(\eta\) between \(r\) and \(r'\) such that

\[
\Phi'(r) = \Phi(r) + \langle \nabla \Phi(\eta), r' - r \rangle = \Phi(r) + \left(\nabla \Phi(\eta), \frac{1}{32 \lambda} \frac{g}{\|g\|_2} + \eta\right)
\]

where we used (3.5) at the end. Using \(\|r - r'\|_2 \leq \frac{1}{16 \lambda}\) and \(\|\pi - r\|_{\infty} \leq \frac{1}{16 \lambda}\) (by assumption), we have \(\|\pi - r\|_{\infty} \leq \frac{1}{5 \lambda}\).

Since \(\Phi(r) \geq 8 n\), we have \(\Phi(\eta) \geq 4 n\) and hence Lemma 14 shows that

\[
\|\nabla \Phi(\eta)\|_2 \leq \frac{1}{3} \|\nabla \Phi(\eta)\|_2.
\]

Using \(g = \nabla \Phi(\pi)\) and letting \(\eta_2 = \nabla \Phi(\pi) - \nabla \Phi(\eta)\), we have

\[
\Phi'(r) - \Phi(r) = \left(\frac{g}{\|g\|_2} - \frac{1}{32 \lambda} \frac{g}{\|g\|_2} + \eta\right) = -\frac{1}{32 \lambda} \|g\|_2 \eta - \frac{1}{32 \lambda} \eta_2 + \frac{1}{3} \|g\|_2 \eta + \frac{1}{3} \eta_2 \eta.
\]

Using \(\|\eta_2\|_2 \leq \frac{1}{32 \lambda} (3.6)\), we have

\[
\Phi'(r) - \Phi(r) \leq -\frac{1}{32 \lambda} \|g\|_2 + \frac{1}{32 \lambda} \cdot \frac{1}{3} \|g\|_2 + \|g\|_2 \cdot \frac{1}{60 \lambda} + \frac{1}{3} \|g\|_2 \cdot \frac{1}{60 \lambda} \leq -\frac{1}{720 \lambda} \|g\|_2
\]

9
Using Lemma 14, we have $$\|g\|_2 \geq \frac{\lambda}{\sqrt{n}} (\Phi(\tau) - n) \geq 3\lambda \sqrt{n}$$. Hence, we have

$$\Phi(r') \leq \Phi(r) - \frac{\sqrt{n}}{240} < 16n.$$ (3.7)

The potential actually decreases in this case. This proves the conclusion about $$\Phi$$.

Exercise 17. Show that we can use the potential function $$\Phi = \sum_{i=1}^{n} \exp(\lambda|v_i|)$$ to get a similar conclusion.

### 3.2 Selecting $$\overline{\pi}, \overline{s}$$ and $$\overline{r}$$

Each step of the robust interior point method solves the linear system

$$\begin{pmatrix} S & X & 0 \\ A & 0 & 0 \\ 0 & I & A^\top \end{pmatrix} \begin{pmatrix} \delta_x \\ \delta_s \\ \delta_y \end{pmatrix} = \begin{pmatrix} \nabla \Phi(\tau) \\ 0 \\ 0 \end{pmatrix}$$

for some vectors $$\overline{\pi}, \overline{s}, \overline{r}$$ such that $$\|\ln \overline{\pi} - \ln x\|_\infty \leq \frac{1}{48}$$, $$\|\ln \overline{s} - \ln s\|_\infty \leq \frac{1}{48}$$, $$\|\overline{r} - r\|_\infty \leq \frac{1}{48\lambda}$$. The key observation is that only a few coordinates of $$x, s$$ and $$r$$ change significantly each step and hence we can maintain the solution of the linear system instead of computing from scratch. In this section, we discuss how to select $$\overline{\pi}, \overline{s}, \overline{r}$$ with as few updates as possible while maintaining the invariants.

First, we observe that $$\ln x, \ln s$$ and $$\ln r$$ change by $$O(1)$$ in $$\ell_2$$ norm in each step.

Lemma 18. Define $$x^{(k)}, s^{(k)}, r^{(k)}$$ according to Lemma 16. Then, $$\|\ln x^{(k+1)} - \ln x^{(k)}\|_2$$, $$\|\ln s^{(k+1)} - \ln s^{(k)}\|_2$$ and $$\|r^{(k+1)} - r^{(k)}\|_2$$ are all bounded by $$1/(8\lambda)$$.

Proof. Lemma 6 shows that

$$\|(x^{(k+1)} - x^{(k)})/x^{(k)}\|_{\mu^{(k)}} \leq \|\overline{\delta}_{\mu}/\mu^{(k)}\|_{\mu^{(k)}}$$ (3.8)

where $$\mu^{(k)} = \overline{\pi}^{(k)} \overline{s}^{(k)}$$ and $$\overline{\pi}^{(k)}, \overline{s}^{(k)}$$ are the $$\overline{\pi}, \overline{s}$$ used in the $$k$$-th step.

To bound $$\mu^{(k)}$$, Lemma 16 shows that the invariant $$\Phi(r^{(k)}) \leq 16n$$ holds and hence Lemma 14 shows that (recall $$\lambda = 16 \log 40n$$):

$$\|(x^{(k)} s^{(k)} - t^{(k)})/t^{(k)}\|_\infty = \|s^{(k)}\|_\infty \leq \frac{\log 32n}{\lambda} \leq \frac{1}{16}.$$  

Together with the fact that $$\|\ln \overline{\pi}^{(k)} - \ln x^{(k)}\|_\infty \leq \frac{1}{48}$$, $$\|\ln \overline{s}^{(k)} - \ln s^{(k)}\|_\infty \leq \frac{1}{48}$$, we have

$$\|\overline{\pi}^{(k)} \overline{s}^{(k)} - r^{(k)}\|_\infty \leq \frac{1}{8}.$$  

Using this on (3.8) gives $$\|(x^{(k+1)} - x^{(k)})/x^{(k)}\|_2 \leq \frac{8}{7} \|\overline{\delta}_{\mu}\|_2$$. Using $$\overline{\delta}_{\mu} = -\frac{t'}{32\lambda} \overline{v}_{\|w\|_2}$$, we have

$$\|(x^{(k+1)} - x^{(k)})/x^{(k)}\|_2 \leq \frac{1}{28\lambda}.$$  

To translate the bound to log scale, we note that $$|\ln(1 + t) - t| \leq 2t$$ for all $$|t| \leq \frac{1}{2}$$ and hence

$$\|\ln x^{(k+1)} - \ln x^{(k)}\|_2 = \|\ln(1 + \frac{x^{(k+1)} - x^{(k)}}{x^{(k)}})\|_2 \leq \frac{1}{14\lambda}.$$  

The bound for $$\|\ln s^{(k+1)} - \ln s^{(k)}\|_2$$ is similar.

The bound for $$\|r^{(k+1)} - r^{(k)}\|_2$$ follows from Lemma 16.  

Now the question is how to select $$\ln \overline{\pi}, \ln \overline{s}$$ and $$\ln \overline{r}$$ such that they are close to $$\ln x, \ln s$$ and $$\ln r$$ in $$\ell_\infty$$ norm. If the cost of updating the inverse of a matrix is linear in the rank of the update, then we can simply update any coordinate of $$\overline{\pi}, \overline{s}$$ and $$\overline{r}$$ whenever they violate the condition. However, due to fast matrix multiplication, the average cost (per rank) of update is lower when the rank of update is large. Therefore, it is beneficial to update coordinates preemptively.
Now we state the algorithm for selecting $\pi$, $s$ and $\tau$. This algorithm is a general algorithm for maintaining a vector $v$ such that $\|\tau - v\|_\infty \leq \delta$. For every $2^k$ steps, the algorithm updates the coordinate of the vector $\tau$ if that coordinate has changed by more than $\delta/(2 \log n)$ between this step and $2^k$ steps earlier.

**Algorithm 4:** SelectVector$(\pi, v^{(0)}, v^{(1)}, \ldots, v^{(k)}, \delta)$

Let $I = \{\}$ be the set of updating coordinates.

for $\ell = 0, 1, \ldots, \lfloor \log n \rfloor$ do

if $k = 0 \mod 2^\ell$ then

if $\ell = \lfloor \log n \rfloor$ then

$\pi = [n]$. 

else

$I = I \cup \{i : |v_i^{(k)} - v_i^{(k-2^\ell)}| \geq \delta/(2 \lfloor \log n \rfloor)\}$. 

end

end

end

$\pi_i \leftarrow v_i^{(k)}$ for all $i \in I$

Return $\pi$

**Lemma 19.** Given vectors $v^{(0)}, v^{(1)}, v^{(2)}, \ldots$ arriving in a stream, suppose that $\|v^{(k+1)} - v^{(k)}\|_2 \leq \beta$ for all $k$. For any $\frac{1}{2} > \delta > 0$, define the vector $\pi^{(0)} = v^{(0)}$ and $\pi^{(k)} = \text{SelectVector}(\pi^{(k-1)}, v^{(0)}, v^{(1)}, \ldots, v^{(k)}, \delta)$. Then, we have that

- $\|\pi^{(k)} - v^{(k)}\|_\infty \leq \delta$ for all $k$.
- $\|\pi^{(k)} - \pi^{(k-1)}\|_0 \leq O(2^{\ell_k}(\beta/\delta)^2 \log^2 n)$ where $\ell_k$ is the largest integer $\ell$ with $k = 0 \mod 2^\ell$.

**Proof.** For bounding the error, we first fix some coordinate $i \in [n]$. Let $k'$ be the iteration when $\pi_i$ was last updated, namely, $\pi_i^{(k')} = v_i^{(k')}$. Since we set $\pi \leftarrow v$ every $2^{\lfloor \log n \rfloor}$ steps, we have $k - 2^{\lfloor \log n \rfloor} \leq k' < k$. We can write $k' = k_0 < k_1 < k_2 < \cdots < k_s = k$ such that $k_{i+1} - k_i$ is a power of 2 and $k_{i+1} - k_i$ divides $k_{i+1}$ with $|s| \leq 2 \lfloor \log n \rfloor$. Hence, we have that

$$v_i^{(k)} - \pi_i^{(k)} = v_i^{(k_s)} - v_i^{(k_0)} = \sum_{j=0}^{s-1} (v_i^{(k_{j+1})} - v_i^{(k_j)}).$$

Since $\pi_i$ is not updated since step $k'$, we have $|v_i^{(k_{i+1})} - v_i^{(k_j)}| \leq \delta/(2 \lfloor \log n \rfloor)$ and hence $|v_i^{(k)} - \pi_i^{(k)}| \leq \delta$. Since this holds for every $i$, we have that $\|\pi^{(k)} - v^{(k)}\|_\infty \leq \delta$.

For the sparsity of $\pi^{(k+1)} - \pi^{(k)}$, we first bound the size of the set $I_\ell \overset{\text{def}}{=} \{i : |v_i^{(k)} - v_i^{(k-2^\ell)}| \geq \delta/(2 \lfloor \log n \rfloor)\}$. Note that

$$|I_\ell| \cdot \frac{\delta^2}{\beta \log^2 n} \leq \sum_{i=1}^n |v_i^{(k)} - v_i^{(k-2^\ell)}|^2 \leq 2^\ell \sum_{i=1}^n \sum_{t=k-2^\ell}^{k-1} |v_i^{(t+1)} - v_i^{(t)}|^2 \leq 2^\ell \beta^2$$

where we used $\|v^{(t+1)} - v^{(t)}\|_2 \leq \beta$ at the end. Hence, we have $|I_\ell| = O(2^\ell (\beta/\delta)^2 \log^2 n)$. Hence, the total number of changes is bounded by

$$|I| \leq \sum_{\ell=0}^{\ell_k} |I_\ell| = O(2^{\ell_k}(\beta/\delta)^2 \log^2 n).$$

\[ \square \]

### 3.3 Inverse Maintenance

In this section, we discuss how to maintain the solution of the linear system (Newton step) efficiently. Although both the matrix and the vector of the Newton step changes during the algorithm, we can simplify by moving the vector inside the matrix.

**Fact 20.** For any invertible matrix $M \in \mathbb{R}^{n \times n}$ and any vector $v \in \mathbb{R}^n$, we have

$$\begin{bmatrix} M & v \\ 0 & -1 \end{bmatrix}^{-1} = \begin{bmatrix} M^{-1} & M^{-1}v \\ 0 & 1 \end{bmatrix}.$$
Hence, the question of maintaining the solution reduces to the problem of maintaining a column of the inverse of the matrix

\[
\begin{pmatrix}
S & X & 0 & \nabla \Phi(\tau)
\
A & 0 & 0 & 0
\
0 & I & A^\top & 0
\
0 & 0 & 0 & -1
\end{pmatrix}.
\]

(3.9)

When we update \(\bar{x}, \bar{s}, \tau\) to \(\bar{x} + \delta_{\bar{x}}, \bar{s} + \delta_{\bar{s}}, \tau + \delta_{\tau}\) with \(q\) coordinates modified in total, there are only \(q\) columns in \(M\) that change. Hence, we can compute the update of the inverse of \(M\) using the Woodbury matrix identity (Equation (3.10)). The idea of using the Woodbury identity together with fast matrix multiplication goes back to Vaidya [18].

**Lemma 21.** Given vectors \(\bar{x}, \bar{s}, \tau \in \mathbb{R}^n\) and the update \(\delta_{\bar{x}}, \delta_{\bar{s}}, \delta_{\tau} \in \mathbb{R}^n\). Let \(q = \|\delta_{\bar{x}}\|_0 + \|\delta_{\bar{s}}\|_0 + \|\delta_{\tau}\|_0\) and \(T_{m,n,\ell}\) be the cost of multiplying an \(m \times n\) matrix with an \(n \times \ell\) matrix. Then,

- Given \(M_{\bar{x},\bar{s},\tau}^{-1}\), we can compute \(M_{\bar{x} + \delta_{\bar{x}},\bar{s} + \delta_{\bar{s}},\tau + \delta_{\tau}}^{-1}\) in time \(O(T_{n,q,n})\).

- Given \(M_{\bar{x},\bar{s},\tau}^{-1}\) and \(M_{\bar{x},\bar{s},\tau}^{-1}b\), we can compute \(M_{\bar{x} + \delta_{\bar{x}},\bar{s} + \delta_{\bar{s}},\tau + \delta_{\tau}}^{-1}b\) in time \(O(T_{q,q,q} + nq)\).

**Proof.** We write \(M_0 = M_{\bar{x},\bar{s},\tau}\) and \(M_1 = M_{\bar{x} + \delta_{\bar{x}},\bar{s} + \delta_{\bar{s}},\tau + \delta_{\tau}}\). Note that \(M_1\) and \(M_0\) are off by just \(q\) entries. Hence, we can write

\[
M_1 = M_0 + UCV
\]

where \(U\) consists of \(q\) columns of identity matrix, \(C\) is a \(q \times q\) matrix and \(V\) consists of \(q\) rows of identity matrix. Hence, the Woodbury matrix identity shows that

\[
M_1^{-1} = (M_0 + UCV)^{-1} = M_0^{-1} - M_0^{-1}U(C^{-1} + VM_0^{-1}U)^{-1}VM_0^{-1}.
\]

(3.10)

Note that \(M_0^{-1}U, VM_0^{-1}U, VM_0^{-1}\) are just blocks of \(M_0^{-1}\) and no computation is needed. Hence, we can compute \((C^{-1} + VM_0^{-1}U)^{-1}\) in the time to invert two \(q \times q\) matrices, which is \(O(T_{q,q,q})\). The rest of the formula can be computed in \(O(T_{n,q,q} + T_{n,q,n}) = O(T_{n,q,n})\) time. In total, the runtime is \(O(T_{n,q,n})\).

For computing \(M_1^{-1}b\), we note that

\[
M_1^{-1}b = M_0^{-1}b - M_0^{-1}U(C^{-1} + VM_0^{-1}U)^{-1}VM_0^{-1}b.
\]

Since \(M_0^{-1}b\) is given, the above formula can be computed in \(O(T_{q,q,q} + nq)\) time where the \(O(nq)\) term comes from multiplying a \(q \times n\) matrix with an \(n\)-vector and a \(n \times q\) matrix with a \(q\)-vector.

To use the previous lemma, we use the following estimate for \(T_{n,r,n}\).

**Definition 22.** The exponent of matrix multiplication \(\omega\) is the infimum among all \(\omega \geq 0\) such that it takes \(n^{\omega + o(1)}\) time to multiply an \(n \times n\) matrix by an \(n \times n\) matrix. The dual exponent of matrix multiplication \(\alpha\) is the supremum among all \(\alpha \geq 0\) such that it takes \(n^{2 + o(1)}\) time to multiply an \(n \times n\) matrix by an \(n \times n^\alpha\) matrix. Currently, \(\omega \leq 2.3729\) [3, 24, 11, 1] and \(\alpha \geq 0.3138\) [11, 5].

**Lemma 23.** For \(r \leq n\), we have \(T_{n,r,n} = n^{2+o(1)} + n^{\omega - \frac{\omega + 2}{\alpha} + o(1)} n^{\frac{\omega + 2}{\alpha}}\).
Lemma 21 shows that it takes $O(n^2 \omega/\ell^2)$ time to compute $\Delta$. Therefore, we compute $\Delta$ too expensive. Rather, we compute $\Delta$ using Lemma 21.

Algorithm 5: FastRobustStep$(A, x, s, t_{\text{start}}, t_{\text{end}})$

Assume $2^{\ell_*} \leq n^\alpha$.
Define $r = (xs - t)/t$ and $\Phi$ according to (3.2) with $\lambda = 16 \log 40n$.
Invariant: $(x, s) \in P^o \times D^o$ and $\Phi(r) \leq 16n$.
Let $t = t_{\text{start}}$, $h = 1/(128\lambda \sqrt{n})$ and $n$ be the number of columns in $A$.
Let $x^{(0)} = \pi^{(0)} = x$, $s^{(0)} = s$, $r^{(0)} = r^{(0)} = (xs - t)/t$.
Let $T = M^{-1}_{\pi^{(0)}, \pi^{(0)}, r^{(0)}}$ (defined in (3.9)) and $u = T e_{2n+d+1}$.

repeat

Let $t' = \text{max}(t/(1+h), t_{\text{end}})$, $\delta = -\frac{\theta}{32\lambda \|x\|_2^2}$, $\tilde{\Phi} = \nabla \Phi(r)$.

if $k = 0 \mod 2^{\ell_*}$ then

Update $T$ to $M^{-1}_{\pi^{(k)}, \pi^{(k)}, r^{(k)}}$ using Lemma 21.

$u \leftarrow T e_{2n+d+1}$, $v \leftarrow u$.
else

Update $v$ to $M^{-1}_{\pi^{(k)}, \pi^{(k)}, r^{(k)}} e_{2n+d+1}$ using vector $u$ and Lemma 21.

end

Let $(\delta_x, \delta_s)$ be the first $2n$ coordinates of $v$.
Let $x^{(k+1)} = x^{(k)} + \delta_x$, $s^{(k+1)} = s^{(k)} + \delta_s$ and $t \leftarrow t'$.
Let $r^{(k+1)} = (x^{(k+1)} - s^{(k+1)})/t$.

$\pi^{(k+1)} = \text{SelectVector}(\pi^{(k)}), \ln x^{(0)}, \ln x^{(1)}, \ldots, \ln x^{(k+1)}, 1/48)$.

$\pi^{(k+1)} = \text{SelectVector}(\pi^{(k)}), \ln s^{(0)}, \ln s^{(1)}, \ldots, \ln s^{(k+1)}, 1/48)$.

$\pi^{(k+1)} = \text{SelectVector}(\pi^{(k)}), r^{(0)}, r^{(1)}, \ldots, r^{(k+1)}, 1/(48\lambda))$.

Set $k \leftarrow k + 1$.

until $t \neq t_{\text{end}}$;
Return $(x, s)$

We note that in the algorithm above, we do not compute the inverse of $M$ in every iteration, which would be too expensive. Rather, we compute $M^{-1}h$ as needed by using the previously computed $M^{-1}$ (from possibly many iterations ago) with a low-rank update using the Woodbury formula that we maintain.

Combining the Lemma 21 with Lemma 19, we have the following guarantee.

Lemma 24. Setting $2^{2\ell_*} = \min(n^\alpha, n^{2/3})$, FastRobustStep (Algorithm 5) takes time

$$O((n^{2\omega/\ell^2} + n^{2+1/6+o(1)} + n^{5/2-\alpha/2+o(1)}) \log(t_{\text{end}}/t_{\text{start}})).$$

Proof. The bottleneck of FastRobustStep is the time to update $v$ and $T$. This depends on the number of coordinates updated in $\pi, \pi, \pi$. Lemma 18 shows that $\ln x$, $\ln s$ and $r$ change by at most $\alpha \equiv 1/(8\lambda)$ in $\ell_2$ norm per step. Since we set the error of SelectVector to be $\delta \equiv 1/(48\lambda)$ (or larger), Lemma 19 shows that $q_k \equiv O(2^{2\ell_k} \log^2 n)$, coordinates in $\pi, \pi, \pi$ are updated at the $k$-th step where $\ell_k$ is the largest integer $\ell$ with $k = 0 \mod 2^\ell$. We can now bound all the computation costs as follows.

Cost of updating $v$: We update $u$ whenever $k = 0 \mod 2^{\ell_*}$. Within that $2^{\ell_*}$ steps, the number of coordinates updated in $\pi, \pi, \pi$ is bounded by

$$q \equiv 2^{\ell_*} - 1 \sum_{k=1}^{2^{\ell_*} - 1} q_k \equiv \sum_{k=1}^{2^{\ell_*} - 1} O(2^{2\ell_k} \log^2 n) = O(2^{2\ell_*} \log^2 n).$$

Therefore, $M^{-1}_{\pi^{(k)}, \pi^{(k)}, r^{(k)}}$ and $T^{-1}$ are off by at most $q$ coordinates. Lemma 21 shows that it takes

$$O(T_{q+q+q} + nq) = \tilde{O}(2^{2\ell_*} \omega + n2^{2\ell_*})$$
time to compute $v = M^{-1}_{\pi^{(k)}, \pi^{(k)}, r^{(k)}} e_{2n+d+1}$ using $u = T e_{2n+d+1}$, where we used $\tilde{O}$ to omit $n^{o(1)}$ terms.

Cost of updating $T$: For the $k$-th step that updates $T$, the number of coordinates updated in $\pi, \pi, \pi$ is bounded by $q + O(2^{2\ell_k} \log^2 n) = O(2^{2\ell_k} \log^2 n)$ where the first term is due to the delayed updates and the second term is due to the updates at that step. Lemma 21 shows that it takes $\tilde{O}(T_{n,n,2^{2\ell_k}})$ time to update $T$. Since $2^{2\ell_k}$ updates
happen every $2^{\ell_*}$ iterations, the amortized cost is

$$\widetilde{O}(\sum_{\ell=\ell_*}^{\frac{1}{2}\log n} 2^{-\ell} T_{n,n,2^{2\ell}}) = \widetilde{O}(\sum_{\ell=\ell_*}^{\frac{1}{2}\log n} (n^{\omega-\frac{\omega-2}{3} \cdot 2^{2\ell} - \frac{2}{3} \cdot 2^{\ell} + n^{2\ell})))$$

$$= \widetilde{O}(\sum_{\ell=\ell_*}^{\frac{1}{2}\log n} n^{\omega-\frac{\omega-2}{3} \cdot 2^{2\ell} - \frac{2}{3} \cdot 2^{\ell} + n^{2\ell} - \ell})$$

where we used Lemma 23. The sum above is dominated by either the term at $\ell = \ell_*$ or the term at $\ell = \frac{1}{2}\log n$. Hence, the amortized cost of updating $T$ is

$$\widetilde{O}(n^{\omega-\frac{\omega-2}{3} \cdot 2^{2\ell} - \frac{2}{3} \cdot 2^{\ell} + n^{2\ell}} + n^{\omega-\frac{1}{2}} + n^{2\ell}) = \widetilde{O}(n^{\omega-\frac{1}{2} + n^{2\ell}})$$

where we used $n^{\omega-\frac{\omega-2}{3} \cdot 2^{2\ell} - \frac{2}{3} \cdot 2^{\ell}} \leq n^2$ since $2^{2\ell} \leq n^a$.

**Cost of initializing $T$ and $u$:** $\widetilde{O}(n^\omega)$.

Since there are $\sqrt{n} \log(t_{end}/t_{start})$ steps, the total cost is

$$\widetilde{O}(n^\omega + \sqrt{n} \log(t_{end}/t_{start}) (2^{2\ell_*} + n^{2\ell_*} + n^{\omega-\frac{1}{2}} + n^{2\ell_*}))$$

$$= \widetilde{O}((n^\omega + n^{2\ell_*} + n^{2\ell_*}))$$

where we used $2^{2\ell_*} \leq n^{6\omega} \leq n$. Putting $2\ell_* = \min(n^\alpha, n^{2/3})$, we have

$$\widetilde{O}((n^\omega + n^{2\alpha + 1/6} + n^{5/2 - \alpha/2}) \log(t_{end}/t_{start})).$$

Following Section 2.4, we can find the initial point by modifying the linear program and this gives the following theorem.

**Theorem 25.** Consider a linear program $\min_{A x = b, x \geq 0} c^T x$ with $n$ variables and $d$ constraints. Assume the linear program has inner radius $r$, outer radius $R$ and Lipschitz constant $L$ (see Definition 9), we can find $x$ such that

$$c^T x \leq \min_{A x = b, x \geq 0} c^T x + 3L,$$

$$A x = b,$$

$$x \geq 0.$$  

in time

$$\widetilde{O}((n^{\omega+o(1)} + n^{2+1/6+o(1)} + n^{5/2 - \alpha/2+o(1)}) \log(R/(\delta r))).$$

If we further assume that the solution $x^* = \arg\min x \in \{A x = b, x \geq 0\}$ is unique and that $c^T x \geq c^T x^* + \eta LR$ for any other vertex $x$ of $\{A x = b, x \geq 0\}$ for some $\eta >\delta \geq 0$, then we have that $\|x - x^*\|_2 \leq \frac{2\delta R}{\eta}$.

**Proof.** The algorithm for find $x$ is the same as SlowSolveLP except that the function L2Step is replaced by the function FastRobustStep. The runtime of FastRobustStep is analyzed in Lemma 24. Since FastRobustStep is a instantiation of RobustStep, its output is analyzed in Lemma 16.

**Historical Note.** The interior-point method was pioneered by Karmarkar [9] and developed in beautiful ways (including [17, 18, 15, 16, 12, 13]). This classical approach appeared to reach its limit of requiring the solution of $\sqrt{n}$ linear systems until the paper of Cohen, Lee and Song [2] which reduced the complexity of approximate linear programming to $n^{\omega+o(1)} \log(1/\epsilon)$, by introducing the robust central path method. Using further insights, their algorithm was derandomized by van den Brand [19]. The technique has been extended in subsequent papers to other optimization problems [14, 7, 23, 8, 20, 6], and has also played a crucial role in faster algorithms for classical combinatorial optimization problems such as matchings and flows [22, 21, 4].

Lemma 26. The modified linear program (Definition 10) has an explicit central path point $x^{(0)} = (x^+, x^-, R)$ at $t$.

Proof. Recall that we say $(x^+, x^-, x^0)$ is on the central path at $t$ if $x^+, x^-, x^0$ are positive and it satisfies the following equation

$$
\begin{align*}
Ax^+ - Ax^- &= b, \\
\sum_{i=1}^{n} x_i^+ + x^0 &= b, \\
A^\top y + \lambda + s^+ &= c, \\
-A^\top y + s^- &= \tilde{c}, \\
\lambda + s^0 &= 0,
\end{align*}
$$

(A.1)

for some $s^+, s^- \in \mathbb{R}_{\geq 0}^n$, $s^0 > 0$, $y \in \mathbb{R}^d$ and $\lambda \in \mathbb{R}$.

Now, we verify the solution $x^+ = \frac{t}{c+\frac{t}{R}}$, $x^- = \frac{t}{c+\frac{t}{R}} - x_o$, $x^0 = \frac{\tilde{R}}{R}$, $x_o = \frac{A^\top (AA^\top)^{-1}b}{y}$, $y = 0$, $s^+ = \frac{t}{x^+}$, $s^- = \frac{t}{x^-}$, $s^0 = \frac{t}{y}$, $\lambda = -s^0$. Using $Ax_o = b$, one can check it satisfies all the equality constraints above.

For the inequality constraints, using $\|c\|_\infty \leq L$ and $t \geq 8LR$, we have

$$
\frac{3R}{4} \leq \frac{t}{L + t/R} \leq x^+_i \leq \frac{t}{-L + t/R} \leq \frac{3R}{2},
$$

(A.2)

and hence $x^+ > 0$ and so is $s^+$. Since $\|x_o\|_2 \leq R \leq \frac{R}{2}$ and $x^+_i \geq \frac{3R}{4}$ for all $i$, we have $x_i \geq 0$ for all $i$. Hence, $x^-$ and $s^-$ are positive. Finally, $x^0$ and $s^0$ are positive. This proves that $(\frac{t}{c+\frac{t}{R}}, \frac{t}{c+\frac{t}{R}} - x_o, \frac{\tilde{R}}{R})$ is on the central path point at $t$. \hfill \square

Next, we show that the near-central-path point $(x, s)$ at $t = LR$ is far from the constraints $x^+ \geq 0$ and is close to the constraints $x^- \geq 0$. The proof for both involves the same idea: use the optimality condition of $x$. Throughout the rest of the section, we are given $(x, s) \in P_{R,t} \times D_{R,t}$ such that $\mu = xs$ satisfies

$$
\frac{5}{6} LR \leq \mu \leq \frac{7}{6} LR.
$$

A Finding a Point on the Central Path

We continue from the discussion in Section 2.4.

First, we show that $x^{(0)}$ defined in Theorem 11 is indeed on the central path of the modified linear program.
We write \( \mu \) into its three parts \((\mu^+, \mu^-, \mu^0)\). By Lemma 4, we have that \( x \) \( \begin{align*} f(x^+, x^-, x^0) &\equiv c^T x^+ + c^T x^- - \sum_{i=1}^{n} \mu_i^+ \log x_i^+ - \sum_{i=1}^{n} \mu_i^- \log x_i^- - \mu^0 \log x^0 \end{align*} \) 
over the domain \( \mathcal{P}_{\mathcal{R}} \). The gradient of \( f \) is a bit complicated. We avoid it by considering the directional derivative at \( x \) along the direction “\( v - x \)” where \( v \) is the point such that \( A v = b \) and \( v \geq r \). Since our domain is in \( \mathcal{P}_{\mathcal{R}} \subset \mathbb{R}^{2n+1} \), we need to lift \( v \) to higher dimension. So we define the point 
\\
\begin{align*} v^- &= \min(x^- , 8L \mathcal{R} R \frac{\mathcal{R}}{t} \cdot R), \\
v^+ &= v + v^-, \\
v^0 &= \tilde{b} - \sum_{i=1}^{n} v_i^+. \\
\end{align*}
\\
First, we need to get some basic bounds on \( \tilde{b} \) and \( \bar{c} \).

**Lemma 27.** We have that \( \frac{3}{4} n \mathcal{R} \leq \tilde{b} \leq 3 n \mathcal{R} \) and \( \bar{c}_i \geq t/(2 \mathcal{R}) \) for all \( i \).

**Proof.** By (A.2), we have \( \frac{3}{4} \mathcal{R} \leq x_{e,i}^+ \leq \frac{3}{2} \mathcal{R} \). By the definition of \( \tilde{b} \), we have 
\\
\begin{align*} \tilde{b} &= \sum_{i=1}^{n} x_{e,i}^+ + \mathcal{R} \geq \frac{3}{4} n \mathcal{R}. \\
\end{align*}
\\
Similarly, we have \( \bar{b} = \sum_i x_i^+ + \mathcal{R} \geq \frac{3}{4} n \mathcal{R} \).

For the bound on \( \bar{c} \), recall that \( \bar{c} = t/x_{\bar{c}}^- \) with \( x_{\bar{c}}^- = x_i^+ - x_o \) and \( x_o = A^T (AA^T)^{-1} b = \arg \min_{A x=b} \|x\|_2 \). Since we assumed the linear program has outer radius \( \mathcal{R} \), we have that \( \|x_o\|_2 \leq \mathcal{R} \). Hence, 
\\
\begin{align*} x_{\bar{c},i}^- \leq \frac{3}{2} \mathcal{R} + \mathcal{R} \leq 2 \mathcal{R}. \\
\end{align*}
\\
Therefore, \( \bar{c} \geq t/(2 \mathcal{R}) \). \( \square \)

The following lemma shows that \( (v^+, v^-, v^0) \in \mathcal{P}_{\mathcal{R}} \).

**Lemma 28.** We have that \( (v^+, v^-, v^0) \in \mathcal{P}_{\mathcal{R}} \). Furthermore, we have \( v^0 \geq \frac{1}{2} n \mathcal{R} \).

**Proof.** Note that \( (v^+, v^-, v^0) \) satisfies the linear constraints of \( \mathcal{P}_{\mathcal{R}} \) by construction. It suffices to prove the vector is positive. Since \( x^- > 0 \), we have \( v^- > 0 \). Since \( v \geq \mathcal{R} \), we also have \( v^+ > 0 \). For \( v^0 \), we use \( \bar{b} \geq \frac{3}{4} n \mathcal{R} \) (Lemma 27), \( v \leq \mathcal{R} \) and \( v^- \leq \frac{8L \mathcal{R} R}{t} \cdot \mathcal{R} \leq R \) to get 
\\
\begin{align*} v^0 &= \bar{b} - \sum_{i=1}^{n} v_i^+ \geq \frac{3}{4} n \mathcal{R} - \sum_{i=1}^{n} (v_i + v_i^-) \geq \frac{1}{2} n \mathcal{R}. \end{align*}
\\
(\text{A.3})

Next, we define the path \( p(t) = (1 - t)(x^+, x^-, x^0) + t(v^+, v^-, v^0) \). Since \( p(0) \) minimizes \( f \), we have that \( \frac{d}{dt} f(p(t)) \big|_{t=0} \geq 0 \). In particular, we have 
\\
\begin{align*} 0 \leq \frac{d}{dt} f(p(t)) \big|_{t=0} &= c^T (v^+ - x^+) + c^T (v^- - x^-) - \sum_{i=1}^{n} \mu_i^+ (v^+ - x^+)_i - \sum_{i=1}^{n} \mu_i^- (v^- - x^-)_i - \mu^0 (v^0 - x^0) \\
&= \frac{\mu^0}{x^0} (x^0 - v^0) + \sum_{i=1}^{n} (c_i - \frac{\mu_i^+}{x_i^+}) (v^+ - x^+_i) + \sum_{i=1}^{n} (c_i - \frac{\mu_i^-}{x_i^-}) (v^- - x^-)_i. \end{align*}
\\
(\text{A.3})

Now, we bound each term one by one. For the first term, we note that 
\\
\begin{align*} \frac{\mu^0}{x^0} (x^0 - v^0) \leq \mu^0 \leq 2 L \mathcal{R}. \end{align*}
\\
(\text{A.4})

For the second term in (A.3), we have the following
Lemma 29. We have that \( \sum_{i=1}^{n} (c_i - \frac{\mu_i^+}{x_i^+})(v^+ - x^+)_i \leq 4nLR - \frac{LRr}{2 \min_{x_i^+}} \).

Proof. Note that
\[
\sum_{i=1}^{n} (c_i - \frac{\mu_i^+}{x_i^+})(v^+ - x^+)_i = \sum_{i=1}^{n} (c_i v_i^+ - \frac{\mu_i^+}{x_i^+} v_i^+ - c_i x_i^+ + \mu_i^+) \\
\leq \sum_{i=1}^{n} c_i v_i^+ + \sum_{i=1}^{n} \mu_i^+ - \sum_{i=1}^{n} \frac{\mu_i^+}{x_i^+} v_i^+ \\
\leq \|c\|_{\infty} \|v^+\|_1 + 2nLR - \frac{1}{2} \sum_{i=1}^{n} \frac{LRr}{x_i^+}
\]
where we used \( \mu_i^+ \in [\frac{LR}{2}, 2LR] \) and \( v_i^+ \geq v_i \geq r \) at the end. The result follows from \( \|c\|_{\infty} \leq L, \|v^+\|_1 \leq \bar{b} \leq 3nR \) (Lemma 27).

For the third term in (A.3), we have the following

Lemma 30. We have that \( \sum_{i=1}^{n} (\tilde{c}_i - \frac{\mu_i^+}{x_i^+})(v^- - x^-)_i \leq 2LR - \frac{t}{4R} \max_{x_i^-} \).

Proof. Using \( v^- = \min(x^-, \frac{8LR}{t} R) \), we have \( v_i^- \leq x_i^- \). We can ignore the terms with \( v_i^- = x_i^- \).

For \( v_i^- < x_i^- \), we have \( x_i^- \geq \frac{8LR}{t} R \). Using \( \tilde{c}_i \geq \frac{t}{2R} \) (Lemma 27), we have
\[
\tilde{c}_i - \frac{\mu_i^+}{x_i^+} \geq \tilde{c}_i - \frac{\mu_i^+}{\frac{8LR}{t} R} \geq \tilde{c}_i - \frac{2LR}{\frac{8LR}{t} R} = \tilde{c}_i - \frac{t}{4R} \geq \frac{t}{4R}
\]
Hence, we have
\[
\sum_{i=1}^{n} (\tilde{c}_i - \frac{\mu_i^+}{x_i^+})(v^- - x^-)_i \leq \frac{t}{4R} \sum_{i=1}^{n} (v^- - x^-)_i \leq \frac{t}{4R} (\frac{8LR}{t} R - \max_{x_i^-})
\]

Combining (A.3), (A.4), Lemma 29 and Lemma 30, we have
\[
0 \leq \frac{\mu^0}{x^0}(x^0 - x_0) + \sum_{i=1}^{n} (c_i - \frac{\mu_i^+}{x_i^+})(v^+ - x^+)_i + \sum_{i=1}^{n} (\tilde{c}_i - \frac{\mu_i^+}{x_i^+})(v^- - x^-)_i \\
\leq 2LR + 4nLR - \frac{LRr}{2 \min_{x_i^+}} + 2LR - \frac{t}{4R} \max_{x_i^-} \\
= 5nLR - \frac{LRr}{2 \min_{x_i^+}} - \frac{t}{4R} \max_{x_i^-}.
\]
Hence, we show that \( (x^+, x^-, x^0) \) is close to the central path at \( t = LR \) implies that \( \min_{x_i^+} \) cannot be too small and \( \max_{x_i^-} \) cannot be too large
\[
\frac{LRr}{2 \min_{x_i^+}} + \frac{t}{4R} \max_{x_i^-} \leq 5nLR.
\]
In particular, this shows the following

Lemma 31. We have that \( \min_{x_i^+} \geq \frac{Rr}{10nR} \) and \( \max_{x_i^-} \leq \frac{20nLR}{t} \).

Now, we are ready to prove the second conclusion of Theorem 11.

Lemma 32. For any primal \( x^0 \in (x^+, x^-, x^0) \in P_{\pi, t} \) and dual \( s^0 \in (s^+, s^-, s^0) \in D_{\pi, t} \) such that \( \frac{1}{6} LR \leq x_i s_i \leq \frac{1}{6} LR \), we have that
\[
(x^+ - x^-, s^+ - s^0) \in P \times D
\]
and that \( x_i^- \leq s_i^+ \) and \( s^0 \leq e s_i^+ \) for all \( i \).
Proof. First we check \( x = x^+ - x^- \in \mathcal{P} \). By the choice of \( \bar{R} \) and \( t \), Lemma 31 shows that

\[
\frac{\max_i x_i^-}{\min_i x_i^+} \leq \frac{20nL\bar{R}}{Rt} \leq \frac{200n^2L\bar{R}^3}{Rt} \leq \epsilon.
\]

Hence, we have \( x^+ - x^- > 0 \) and that \( A(x^+ - x^-) = b \).

Next, we check \( s \overset{\text{def}}{=} s^+ - s^\theta \in \mathcal{D} \). Since \( x \in \mathcal{P} \), we have \( x \leq R \) and \( x^+ \leq \frac{3}{2}x \leq \frac{3}{2}R \). Since \( x_i^+ s^+_i \geq \frac{5}{6}LR \), we have \( s^+_i \geq \frac{1}{2}L \). On the other hand, we have \( x^\theta = \bar{b} - \sum_{i=1}^n x^+_i \geq \bar{b} - 2n\bar{R} \geq \frac{1}{2}n\bar{R} \) (Lemma 27). Hence, \( s^\theta \leq \frac{5LR}{4nR} \leq \frac{5LR}{2nR} \).

Combining both and the choice of \( \bar{R} \), we have

\[
\frac{s^\theta}{\min_i s_i^+} \leq \frac{5LR}{2nR} \leq \frac{5R}{nR} \leq \epsilon.
\]

Hence, we have \( s = s^+ - s^\theta > 0 \) and that \( A^\top y + s = A^\top y + s^+ - s^\theta = A^\top y + s^+ + \lambda = c \) (See (A.1)). \( \square \)

To ensure the reduction does not increase the complexity of solving linear system, we note that the linear constraint in the modified linear program is

\[
\bar{X} = \begin{bmatrix}
A & -A & 0 \\
1 & 0 & 1
\end{bmatrix}
\]

For any diagonal matrices \( W_1, W_2 \) and any scalar \( \alpha \), we have

\[
H \overset{\text{def}}{=} \bar{X} \begin{bmatrix}
W_1 & 0 & 0 \\
0 & W_2 & 0 \\
0 & 0 & \alpha
\end{bmatrix} \bar{X}^\top = \begin{bmatrix}
A^\top(W_1 + W_2)A & Aw_1 \\
(Aw_1)^\top & \|w_1\|_1 + \alpha
\end{bmatrix}.
\]

Note that the second row and second column block has size 1. By the block inverse formula (Fact 20), \( H^{-1}v \) is an explicit formula involving \( (A^\top(W_1 + W_2)A)^{-1}v_{1:n} \) and \( (A^\top(W_1 + W_2)A)^{-1}Aw_1 \). Hence, we can compute \( H^{-1}v \) by solving two linear systems of the form \( A^\top WA \) with some extra linear work.
