Abstract

We consider a series of massive scaling limits \( m_1 \to \infty, q \to 0, \lim m_1 q = \Lambda_3 \) followed by \( m_4 \to \infty, \Lambda_3 \to 0, \lim m_4 \Lambda_3 = (\Lambda_2)^2 \) of the \( \beta \)-deformed matrix model of Selberg type \((N_c = 2, N_f = 4)\) which reduce the number of flavours to \( N_f = 3 \) and subsequently to \( N_f = 2 \). This keeps the other parameters of the model finite, which include \( n = N_L \) and \( N = n + N_R \), namely, the size of the matrix and the ”filling fraction”. Exploiting the method developed before, we generate instanton expansion with finite \( g_s, \epsilon_{1,2} \) to check the Nekrasov coefficients \((N_f = 3, 2 \text{ cases})\) to the lowest order. The limiting expressions provide integral representation of irregular conformal blocks which contains a 2d operator \( \lim \frac{1}{C(q)} : e^{(1/2)\alpha_1 \phi(0)} : (\int_0^q dz : e^{b \phi(z)} :)^n : e^{(1/2)\alpha_2 \phi(q)} : \) and is subsequently analytically continued.
1 Introduction

There has already been an ample amount of literature on the Seiberg-Witten prepotential for the cases when massive flavours are present. Just restricting our attention to the $SU(2)$ case, a partial list includes \cite{1, 2, 3, 4, 5, 6, 7, 8, 9}. In particular, ref. \cite{4, 5} compute the prepotentials of lower flavours as decoupling limits of those of higher flavors.

In the recent intense activities on the conjectured equivalence between the (irregular) conformal block and the Nekrasov partition function \cite{10, 11, 12, 13, 14} (for a partial proof, \cite{15, 16}), the discussions of these decoupling limits are further advanced and augmented to contain the parameters $g_s$, $\epsilon_{1,2}$ of genus expansion and quantization and are derived both from $2d - 6d$ perspective of the Riemann surface \cite{17} and from the Shapovalov form \cite{18, 19, 20}.

Somewhat separately, the relevance of the $\beta$ deformation of the one-matrix model \cite{21} and that of the more general quiver matrix model \cite{21, 22} to the above equivalence have been noted. At the planar level, both the spectral curve of the one-matrix model \cite{21} and that of the quiver matrix model \cite{22} are shown to be isomorphic to the corresponding Seiberg-Witten curve written in the Witten-Gaiotto form \cite{23, 24}. (For a check of the decoupling limits at the planar free energy, see \cite{25}).

The connection between the conformal block and the $\beta$ deformed matrix model becomes firmer through the Dotsenko-Fateev integral integral representation \cite{26, 27, 28, 29}. In particular, the first few Nekrasov coefficients are derived and the $0d - 4d$ dictionary has been established in \cite{29}. See also \cite{30, 31, 32, 33, 34, 35, 36, 37, 38}. This representation permits rigorous treatments for arbitrary values of $g_s$ and $\epsilon_{1,2}$. In this paper, we will consider a series of massive scaling limits which reduce the number of flavours to $N_f = 3$ and subsequently to $N_f = 2$, using the technology established in \cite{29}. The way in which these limits are taken is different from that considered on the basis of the Shapovalov form \cite{18, 20}. The limiting expressions provide integral representation of irregular conformal blocks which contains a $2d$ operator $\lim_{\gamma \to q} \frac{1}{C(q)} : e^{(1/2)\alpha_1 \phi(0)} : (\int_0^\gamma dz : e^{b_k \phi(z)} : )^n : e^{(1/2)\alpha_2 \phi(q)} :$ and is subsequently analytically continued.

A similar consideration at higher (say five) point conformal block yields interesting chiral 3 and 4 point functions to study.

In the next section, we briefly recall \cite{29}. In the section three, we take the massive scaling limit to the three flavour case and generate its first expansion coefficient. In section four, we subsequently take the limit to the two flavour case and generate its first expansion coefficient. In the appendix, the contour deformations assumed in section three and four are justified.
2 Review of generic four point conformal block represented by Selberg type matrix model

The Dotsenko-Fateev multiple integral is an integral representation of the generic 4-point conformal block \( \mathcal{F}(q|c;\Delta_1,\Delta_2,\Delta_3,\Delta_4,\Delta_f) \). In \cite{29}, we have managed to put this into the form of the perturbed double-Selberg matrix model. Renaming the same quantity as \( \mathcal{F} \) as \( Z_{\text{pert}}^{(\text{Selberg})^2} \), we have obtained

\[
Z_{\text{pert}}^{(\text{Selberg})^2} = q^\sigma (1 - q)^{(1/2)\alpha_2 \alpha_3} \\
\times \left( \prod_{I=1}^{N_L} \int_0^1 dx_I \right) \left( \prod_{I=1}^{N_L} x_I^{b_E \alpha_1} (1 - x_I)^{b_E \alpha_2} (1 - qx_I)^{b_E \alpha_3} \right) \prod_{1 \leq I < J \leq N_L} |x_I - x_J|^{2b_E^2} \\
\times \left( \prod_{J=1}^{N_R} \int_0^1 dy_J \right) \left( \prod_{J=1}^{N_R} y_J^{b_E \alpha_4} (1 - y_J)^{b_E \alpha_3} (1 - qy_J)^{b_E \alpha_2} \right) \prod_{1 \leq I < J \leq N_R} |y_I - y_J|^{2b_E^2} \\
\times \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} (1 - qx_I y_J)^{2b_E^2}.
\]

Here \( n := N_L \) and \( N_R := N - n \) are originally the number of the screening operators we put between 0 and \( q \) and that between 1 and \( \infty \) respectively. The remaining parameters are related to those of the original conformal block by \( c = 1 - 6Q_E^2, Q_E = b_E - (1/b_E), \Delta_i = (1/4)\alpha_i(\alpha_i - 2Q_E), \Delta_f = (1/4)\alpha_f(\alpha_f - 2Q_E) \). Also

\[
\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 + 2(N_L + N_R)b_E = 2Q_E. \tag{2.2}
\]

\[
\sigma := \frac{1}{2} \alpha_1 \alpha_2 + N_L + N_Lb_E(\alpha_1 + \alpha_2) + N_L(N_L - 1)b_E^2. \tag{2.3}
\]

The Selberg integral is denoted by

\[
S_N(\beta_1, \beta_2, \gamma) = \left( \prod_{I=1}^{N} \int_0^1 dx_I \right) \left( \prod_{I=1}^{N} x_I^{\beta_1 - 1} (1 - x_I)^{\beta_2 - 1} \right) \prod_{1 \leq I < J \leq N} |x_I - x_J|^{2\gamma}. \tag{2.4}
\]

The Selberg integral \((2.4)\) is convergent \cite{39} and equals to

\[
S_N(\beta_1, \beta_2, \gamma) = \prod_{j=1}^{N} \frac{\Gamma(1+j\gamma)\Gamma(\beta_1 + (j-1)\gamma)\Gamma(\beta_2 + (j-1)\gamma)}{\Gamma(1+\gamma)\Gamma(\beta_1 + \beta_2 + (N+j-2)\gamma)}, \tag{2.5}
\]

when \( N \) is a positive integer and the complex parameters above obey

\[
\Re \beta_1 > 0, \quad \Re \beta_2 > 0, \quad \Re \gamma > -\min \left\{ \frac{1}{N}, \frac{\Re \beta_1}{N-1}, \frac{\Re \beta_2}{N-1} \right\}. \tag{2.6}
\]
The perturbed double-Selberg model (2.1) has a well-defined $q$-expansion if

$$\text{Re}(b_E \alpha_i) > -1, \quad (i = 1, 2, 3, 4), \quad (2.7)$$

$$\text{Re}(b_E^2) > -\min \left\{ \frac{1}{N_L}, \frac{1}{N_R}, \frac{\text{Re}(b_E \alpha_1) + 1}{N_L - 1}, \frac{\text{Re}(b_E \alpha_2) + 1}{N_L - 1}, \frac{\text{Re}(b_E \alpha_3) + 1}{N_R - 1}, \frac{\text{Re}(b_E \alpha_4) + 1}{N_R - 1} \right\}, \quad (2.8)$$

and $|q| < 1$.

Let

$$Z_{(\text{Selberg})^2}(b_E; N_L, \alpha_1, \alpha_2; N_R, \alpha_4, \alpha_3) = Z_{\text{Selberg}}(b_E; N_L, \alpha_1, \alpha_2) Z_{\text{Selberg}}(b_E; N_R, \alpha_4, \alpha_3) \quad (2.9)$$

Averaging with respect to $Z_{(\text{Selberg})^2}$, $Z_{\text{Selberg}}(N_L)$ and $Z_{\text{Selberg}}(N_R)$ is denoted by $\langle \langle \cdots \rangle \rangle_{N_L, N_R}$, $\langle \langle \cdots \rangle \rangle_{N_L}$ and $\langle \langle \cdots \rangle \rangle_{N_R}$ respectively.

The $q$-expansion of the perturbed double-Selberg model is a special case of that of more general perturbed Selberg model and is exactly calculable. Consider the following function

$$Z_{\text{pert-Selberg}}(\beta_1, \beta_2, \gamma; \{g_i\}) := S_N(\beta_1, \beta_2, \gamma) \left\langle \exp \left( \sum_{I=1}^{N} W(x_I; g) \right) \right\rangle_N, \quad (2.10)$$

where the averaging is with respect to the Selberg integral (2.3) and

$$W(x; g) = \sum_{i=0}^{\infty} g_i x^i. \quad (2.11)$$

Let us expand the exponential of the potential into the Jack polynomials

$$\exp \left( \sum_{I=1}^{N} W(x_I; \{g_i\}) \right) = \sum_{\lambda} C_{(\gamma)}^{(\lambda)}(g) P_{\lambda}^{(1/\gamma)}(x). \quad (2.12)$$

Here $P_{\lambda}^{(1/\gamma)}(x)$ is a polynomial of $x = (x_1, \cdots, x_N)$ and $\lambda = (\lambda_1, \lambda_2, \cdots)$ is a partition: $\lambda_1 \geq \lambda_2 \geq \cdots \geq 0$. Jack polynomials are the eigenstates of

$$\sum_{I=1}^{N} \left( x_I \frac{\partial}{\partial x_I} \right)^2 + \gamma \sum_{1 \leq i < j \leq N} \left( \frac{x_I + x_J}{x_I - x_J} \right) \left( x_I \frac{\partial}{\partial x_I} - x_J \frac{\partial}{\partial x_J} \right), \quad (2.13)$$

with homogeneous degree $|\lambda| = \lambda_1 + \lambda_2 + \cdots$ and are normalized such that for dominance ordering

$$P_{\lambda}^{(1/\gamma)}(x) = m_\lambda(x) + \sum_{\mu < \lambda} a_{\lambda \mu} m_\mu(x). \quad (2.14)$$
Here $m_\lambda(x)$ is the monomial symmetric polynomial.

Let $\lambda'$ be the conjugate partition of $\lambda$, i.e., whose diagram of partition is the transpose of that of $\lambda$ along the main diagonal. Then Macdonald-Kadell integral \[40, 41, 42\] implies that

$$
\left\langle P^{(1/\gamma)}_\lambda(x) \right\rangle_N = \prod_{i \geq 1} \frac{(\beta_1 + (N - i)\gamma)_{\lambda_i}}{(\beta_1 + \beta_2 + (2N - 1 - i)\gamma)_{\lambda_i}} \prod_{(i,j) \in \lambda} \frac{1}{(\lambda_i - j + (\lambda'_j - i + 1)\gamma)},
$$

(2.15)

where $(a)_n$ is the Pochhammer symbol:

$$(a)_n = a(a + 1) \cdots (a + n - 1), \quad (a)_0 = 1.$$  

(2.16)

Computation of (2.10) reduces to that of the expansion coefficient $s_{C}(\gamma)_{\lambda}(g)$. An important relation established in [29] is the 0d-4d version of the AGT relation. It reads

$$
b_{E}N_{L} = \frac{a - m_{2}}{g_{s}}, \quad b_{E}N_{R} = -\frac{a + m_{3}}{g_{s}},
$$

$$
\alpha_{1} = \frac{1}{g_{s}}(m_{2} - m_{1} + \epsilon), \quad \alpha_{2} = \frac{1}{g_{s}}(m_{2} + m_{1}),
$$

$$
\alpha_{3} = \frac{1}{g_{s}}(m_{3} + m_{4}), \quad \alpha_{4} = \frac{1}{g_{s}}(m_{3} - m_{4} + \epsilon).
$$

(2.17)

Also $b_{E} = \epsilon_{1}/g_{s}$ and $\epsilon = \epsilon_{1} + \epsilon_{2}$, $(1/b_{E}) = -\epsilon_{2}/g_{s}$. These relations convert the seven parameters of the matrix model

$$
b_{E}, \quad N_{L}, \quad \alpha_{1}, \quad \alpha_{2}, \quad N_{R}, \quad \alpha_{4}, \quad \alpha_{3}
$$

under the constraint (2.2) into the six unconstrained parameters of the $\mathcal{N} = 2$ $SU(2)$ gauge theory with $N_{f} = 4$:

$$
\frac{\epsilon_{1}}{g_{s}}, \quad \frac{a}{g_{s}}, \quad \frac{m_{1}}{g_{s}}, \quad \frac{m_{2}}{g_{s}}, \quad \frac{m_{3}}{g_{s}}, \quad \frac{m_{4}}{g_{s}}.
$$

(2.19)

3 The limit $m_{1} \to \infty$: from $N_{f} = 4$ to $N_{f} = 3$

First, let us consider the limit $m_{1} \to \infty$, $q \to 0$, keeping $\Lambda_{3} = m_{1}q$ finite. Due to the left-right reflection symmetry, this limit is equivalent to the limit $m_{4} \to \infty$, $q \to 0$, with $m_{4}q$ fixed. Without loss of generality, we therefore restrict ourselves to the former one. Let $q_{3} = \Lambda_{3}/g_{s}$. Under this limit, the parameters $\alpha_{3}, \quad \alpha_{4}, \quad b_{E}, \quad N_{L}, \quad N_{R}$ are unchanged and

$$
\lim_{q \to 0} q\alpha_{1} = -q_{3}, \quad \lim_{q \to 0} q\alpha_{2} = q_{3}.
$$

(3.1)

Note that

$$
\alpha_{1} + \alpha_{2} = \frac{2m_{2} + \epsilon}{g_{s}}
$$

(3.2)
remains finite in this limit. This is why we take the limit $m_1 \to \infty$ instead of $m_2 \to \infty$. But in the naive limit $m_1 \to \infty$ of $Z_{\text{pert}}-(\text{Selberg})^2$ (2.1) diverges since $\text{Re}(b_E \alpha_1) \to -\infty$ which is in the outside of the parameter region (2.7). Hence, we should modify the multiple integral (2.1) before taking the limit.

In order to examine this limit, we first rescale the integration variable $s_I$ as $z_I = q x_I$:

$$Z_{\text{pert}}-(\text{Selberg})^2 = q^{(1/2)\alpha_1 \alpha_2} (1 - q)^{(1/2)\alpha_2 \alpha_3} \left( \prod_{I=1}^{N_L} \int_0^q d z_I \right) \left( \prod_{J=1}^{N_R} \int_0^1 d y_J \right)$$

$$\times \prod_{I=1}^{N_L} \frac{b_E (\alpha_1 + \alpha_2)}{z_I} \left( \frac{q}{z_I} - 1 \right)^{b_E \alpha_2} (1 - z_I)^{b_E \alpha_3} \prod_{1 \leq I < J \leq N_L} |z_I - z_J|^{2 b_E^2}$$

$$\times \prod_{J=1}^{N_R} y_J^{b_E \alpha_4 + 2 b_E^2 N_L} (1 - y_J)^{b_E \alpha_3} (1 - q y_J)^{b_E \alpha_2} \prod_{1 \leq I < J \leq N_R} |y_I - y_J|^{2 b_E^2}$$

$$\times \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( \frac{1}{y_J} - z_I \right)^{2 b_E^2}.$$  

(3.3)

The multiple integral part can be written as follows

$$\left( \prod_{J=1}^{N_R} \int_0^1 d y_J \right) \Phi(y) \prod_{J=1}^{N_R} y_J^{b_E \alpha_4 + 2 b_E^2 N_L} (1 - y_J)^{b_E \alpha_3} (1 - q y_J)^{b_E \alpha_2} \prod_{1 \leq I < J \leq N_R} |y_I - y_J|^{2 b_E^2},$$  

(3.4)

where

$$\Phi(y) := \left( \prod_{I=1}^{N_L} \int_0^q d z_I \right) \prod_{I=1}^{N_L} \frac{b_E (\alpha_1 + \alpha_2)}{z_I} \left( \frac{q}{z_I} - 1 \right)^{b_E \alpha_2} (1 - z_I)^{b_E \alpha_3}$$

$$\times \prod_{1 \leq I < J \leq N_L} |z_I - z_J|^{2 b_E^2} \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( \frac{1}{y_J} - z_I \right)^{2 b_E^2}. \quad (3.5)$$

We assume that by using certain contour integral, the integration path $[0, q]$ can be converted to some path $C_q'$

$$\Phi(y) = C(q) \left( \prod_{I=1}^{N_L} \int_{C_q'} d z_I \right) \cdots.$$  

(3.6)

Here $C(q)$ is a constant which also depends on other parameters. Justification of this assumption is given in Appendix.

---

1. For simplicity, we assume that $b_E$ is real and positive.
2. In the original variable $x_I$, this contour $C_q'$ corresponds to the contour $\hat{C}_\rho$ in the Appendix. See the left of Figure 3.
In the limit $q \to 0$,
\[
\lim_{q \to 0} \frac{1}{C(q)} \Phi(y) = \left( \prod_{I=1}^{N_L} \int_{c_0}^{c_c} dz_I \right) \left( \prod_{J=1}^{N_R} \int_{0}^{1} dy_J \right) \prod_{I=1}^{N_L} z_I^{b_E(\alpha_1 + \alpha_2)} \exp \left( - \frac{b_E q_3}{z_I} \right) (1 - z_I)^{b_E \alpha_3} \times \prod_{1 \leq I < J \leq N_L} (z_I - z_J)^{2b_E^2} \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( \frac{1}{y_J} - z_I \right)^{2b_E^2}. \tag{3.7}
\]

Therefore, we have
\[
Z^{(3)} := \lim_{q \to 0} \frac{q^{-\frac{1}{2}(\alpha_1 \alpha_2)} (1 - q)^{-\frac{1}{2} \alpha_2 \alpha_3}}{C(q)} Z_{\text{pert}-\text{(Selberg)}^2}
\]
\[
= \left( \prod_{I=1}^{N_L} \int_{c_0}^{c_c} dz_I \right) \left( \prod_{J=1}^{N_R} \int_{0}^{1} dy_J \right) \prod_{I=1}^{N_L} z_I^{b_E(\alpha_1 + \alpha_2)} \exp \left( - \frac{b_E q_3}{z_I} \right) (1 - z_I)^{b_E \alpha_3} \prod_{1 \leq I < J \leq N_L} (z_I - z_J)^{2b_E^2} \times \prod_{J=1}^{N_R} y_J^{b_E \alpha_3} (1 - y_J)^{b_E \alpha_3} \prod_{1 \leq I < J \leq N_R} |y_I - y_J|^{b_E^2} \times \prod_{1 \leq I < J \leq N_L} |y_I - y_J|^{b_E^2}.
\tag{3.8}
\]

Here we have changed $z_I = b_E q_3 / w_I$ and
\[
b_E \hat{\alpha}_1 := -2 - 2(N_L - 1)b_E^2 - b_E (\alpha_1 + \alpha_2), \tag{3.9}
\]
\[
\hat{\sigma} := N_L + b_E N_E (\alpha_1 + \alpha_2) + N_L(N_L - 1)b_E^2. \tag{3.10}
\]

Using 0d-4d dictionary, we find
\[
\hat{\alpha}_1 = \frac{\epsilon - 2a}{g_s}. \tag{3.11}
\]

The contour $C$ for $w_I$ is shown in Fig. 1.

The radius of the arc around the origin of this contour $C$ is assumed to be greater than 1. Then, on the contour $C$, it holds that $|w_I| > 1$. Hence this multiple integral can serve as a well-defined generating function of the $q_3$-expansion.

Without specifying the integration contours, the large $N$-limit of this type of ensemble average was studied in [25].
Figure 1: Integration contour $C$.

Let
\[ T_N(\beta, \gamma) := \left( \prod_{I=1}^{N} \int_{C} dw_I \right) \prod_{I=1}^{N} w_I^{\beta-1} e^{-w_I} \prod_{1 \leq I < J \leq N} \left( w_I - w_J \right)^{2\gamma}. \]  

(3.12)

Now we have
\[ Z^{(3)} = \left\langle \left\langle \prod_{I=1}^{N_L} \left( 1 - \frac{b_E q_3}{w_I} \right)^{b_E \alpha_3} \prod_{I=1}^{N_R} e^{-b_E q_3 y_I} \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( 1 - \frac{b_E q_3 y_J}{w_I} \right)^{2b_E^2} \right\rangle \right\rangle_{N_L, N_R}, \]

(3.13)

where the averaging $\left\langle \left\langle \cdots \right\rangle \right\rangle_{N_L, N_R}$ is with respect to $T_{N_L}(1 + b_E \hat{\alpha_1}, b_E^2) S_{N_R}(1 + b_E \alpha_4, 1 + b_E \alpha_3, b_E^2)$.

Recall that $x_I = b_E q_3 / (q w_I) = b_E m_1 / (g_s w_I)$. By taking the limit of the Macdonald-Kadell formula, we have
\[ \left\langle \left\langle P_{\lambda'}^{(1/b_E^2)}(1/w) \right\rangle \right\rangle_{N_L}, \]

(3.14)

Here $P_{\lambda'}^{(1/b_E^2)}(1/w)$ is the Jack symmetric polynomials in $\{1/w_I\}_{1 \leq I \leq N_L}$ and $\lambda'$ is the conjugate partition of $\lambda$.

### 3.1 First expansion coefficient

Let us consider the following $\Lambda_3$-expansion:
\[ \mathcal{A}_{(3)}^{(b_E q_3)} := \left\langle \left\langle \prod_{I=1}^{N_L} \left( 1 - \frac{b_E q_3}{w_I} \right)^{b_E \alpha_3} \prod_{J=1}^{N_R} e^{-b_E q_3 y_I} \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( 1 - \frac{b_E q_3 y_J}{w_I} \right)^{2b_E^2} \right\rangle \right\rangle_{N_L, N_R}, \]

(3.15)

\[ = 1 + \sum_{\ell=1}^{\infty} \Lambda_{\delta}^{\ell} \mathcal{A}_{(3)}^{(b_E q_3)}. \]
We have

\[
A_1^{(3)} = -\frac{\alpha_3}{g_s} \left\langle \sum_{I=1}^{N_L} \frac{b_E^2}{w_I} \right\rangle_{N'_L} - \frac{1}{g_s} \left\langle b_E \sum_{J=1}^{N_R} y_J \right\rangle_{N_R} - 2 \frac{1}{g_s} \left\langle \sum_{I=1}^{N_L} \frac{b_E^2}{w_I} \right\rangle_{N'_L} \left\langle b_E \sum_{J=1}^{N_R} y_J \right\rangle_{N_R}.
\]

(3.16)

By using

\[
\left\langle b_E^2 \sum_{I=1}^{N_L} \frac{1}{w_I} \right\rangle_{N'_L} = \frac{b_E N_L}{\alpha_1} = \left( a - m_2 \right) \left( \epsilon - 2a \right),
\]

(3.17)

\[
\left\langle b_E \sum_{J=1}^{N_R} y_J \right\rangle_{N_R} = \frac{b_E N_R (b_E N_R - Q_E + \alpha_4)}{(a_3 + \alpha_4 + 2b_E N_R - 2Q_E)} = -\frac{(a + m_3)(a + m_4)}{g_s (2a + \epsilon)},
\]

(3.18)

we have

\[
A_1^{(3)} = \frac{(a + m_2)(a + m_3)(a + m_4)}{2a(2a + \epsilon)g_s^2} - \frac{(a - m_2)(a - m_3)(a - m_4)}{2a(2a - \epsilon)g_s^2}.
\]

(3.19)

This is equivalent to the first Nekrasov function \(Z_1^{\text{Nek}}\) for \(SU(2)\) with \(N_f = 3\).

4 The limit \(m_4 \to \infty\): from \(N_f = 3\) to \(N_f = 2\)

Next, we consider the limit \(m_4 \to \infty, A_3 \to 0\), keeping \((A_2)^2 := m_4 A_3\) finite. Note that in this limit \(q_3 = \Lambda_3/g_s \to 0\). Let \(q_2 := \Lambda_2/g_s\). Under this limit,

\[
\lim_{q_3 \to 0} \alpha_3 q_3 = q_2^2, \quad \lim_{q_3 \to 0} \alpha_4 q_3 = -q_2^2,
\]

(4.1)

and the following combination of the parameters

\[
\alpha_1 + \alpha_2 = \frac{2m_2 + \epsilon}{g_s}, \quad \alpha_3 + \alpha_4 = \frac{2m_3 + \epsilon}{g_s},
\]

(4.2)

remain finite and \(b_E, N_L, N_R\) are unchanged.

Recall that

\[
(b_E q_3)^{-3} Z^{(3)} = \left( \prod_{I=1}^{N_L} \int_{\mathcal{C}} dw_I \right) \left( \prod_{I=1}^{N_L} w_I^{b_E \alpha_1} e^{-w_I} \prod_{1 \leq I < J \leq N_L} (w_I - w_J)^{2b_E^2} \right) \times \left( \prod_{J=1}^{N_R} \int_0^1 dy_J \right) \left( \prod_{J=1}^{N_R} y_J^{b_E \alpha_3} (\frac{1}{y_J} - 1)^{b_E \alpha_3} \prod_{1 \leq I < J \leq N_R} |y_I - y_J|^{2b_E^2} \right) \times \left( \prod_{I=1}^{N_L} \left( 1 - \frac{b_E q_3}{w_I} \right) \right) \left( \prod_{J=1}^{N_R} e^{-b_E q_3 y_J} \right) \left( \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( 1 - \frac{b_E q_3 y_J}{w_I} \right)^{2b_E^2}. \right.
\]

(4.3)
By setting \( y_J = b_E \alpha_3 / u_J \), we have

\[
(b_E q_3)^{-\hat{\alpha}} Z^{(3)} = (b_E \alpha_3)^{\hat{\alpha}'} \left( \prod_{I=1}^{N_L} \int_C dJ_I \right) \prod_{I=1}^{N_L} e^{b_E \alpha_3 J_I} \left( w_I - w_J \right)^{2b_E^2} 
\]

\[
\times \left( \prod_{J=1}^{N_R} \int_C dJ_J \right) \prod_{J=1}^{N_R} e^{b_E \alpha_3 J_J} \left( \frac{u_J}{b_E \alpha_3} - 1 \right)^{b_E \alpha_3} \prod_{1 \leq I < J \leq N_L} (w_I - w_J)^{2b_E^2} 
\]

\[
\times \prod_{I=1}^{N_L} \left( 1 - \frac{b_E q_3}{w_I} \right)^{b_E \alpha_3} \prod_{J=1}^{N_R} \prod_{I=1}^{N_L} \left( 1 - \frac{b_E^2 q_3 \alpha_3^2}{w_I u_J} \right)^{2b_E^2}, 
\]

where

\[
b_E \alpha_4 := -2 - b_E (\alpha_3 + \alpha_4) - 2(N_R - 1)b_E^2, 
\]

\[
\hat{\alpha}' := N_E + b_E N_R (\alpha_3 + \alpha_4) + N_R (N_R - 1)b_E^2. 
\]

Note that

\[
\hat{\alpha}_4 = \frac{\epsilon + 2a}{g_s}. 
\]

As in the first limit (from \( N_f = 4 \) to 3), we assume that the integration over \( u_J \) in the path \( [b_E \alpha_3, \infty] \) can be converted into contour integral over certain path \( \mathcal{C}_q_3 \). When converting all \( u_J \) integrals, we denote an overall constant \( C'(b_E q_3) \).

We also assume that

\[
Z^{(2)} := \lim_{q_3 \to \infty} \frac{(b_E q_3)^{-\hat{\alpha}} (b_E \alpha_3)^{-\hat{\alpha}'}}{C'(b_E q_3)} Z^{(3)} 
\]

\[
= \left( \prod_{I=1}^{N_L} \int_C dJ_I \right) \prod_{I=1}^{N_L} e^{b_E \alpha_3 J_I} \left( w_I - w_J \right)^{2b_E^2} 
\]

\[
\times \left( \prod_{J=1}^{N_R} \int_C dJ_J \right) \prod_{J=1}^{N_R} e^{b_E \alpha_3 J_J} \left( \frac{u_J}{b_E \alpha_3} - 1 \right)^{b_E \alpha_3} \prod_{1 \leq I < J \leq N_L} (w_I - w_J)^{2b_E^2} 
\]

\[
\times \prod_{I=1}^{N_L} \exp \left( -\frac{(b_E q_2)^2}{w_I} \right) \prod_{J=1}^{N_R} \exp \left( -\frac{(b_E q_2)^2}{u_J} \right) \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( 1 - \frac{(b_E q_2)^2}{w_I u_J} \right)^{2b_E^2}. 
\]

Hence

\[
Z^{(2)} = T_{N_L} (1 + b_E \alpha_1, b_E^2) T_{N_R} (1 + b_E \alpha_4, b_E^2) 
\]

\[
\times \left\{ \prod_{I=1}^{N_L} \exp \left( -\frac{(b_E q_2)^2}{w_I} \right) \prod_{J=1}^{N_R} \exp \left( -\frac{(b_E q_2)^2}{u_J} \right) \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( 1 - \frac{(b_E q_2)^2}{w_I u_J} \right)^{2b_E^2} \right\}^{N_L', N_R'}. 
\]

Here the averaging \( \langle \cdots \rangle_{N_L', N_R'} \) is with respect to \( T_{N_L} (1 + b_E \alpha_1, b_E^2) T_{N_R} (1 + b_E \alpha_4, b_E^2) \).
Also we have the formula for the average of the Jack symmetric polynomials $P^{(1/b_E^2)}_\lambda(1/u)$ of $\{1/u_J\}_{1 \leq J \leq N_R}$:

$$
\left\langle P^{(1/b_E^2)}_\lambda(1/u) \right\rangle_{N_R}^\lambda = \left( -\frac{g_2^2}{\epsilon_1} \right)^{|\lambda|} \prod_{(i,j) \in \lambda} \frac{(a + m_3 + \epsilon_1(i - 1) + \epsilon_2(j - 1))}{(2a + \epsilon + \epsilon_1(i - 1) + \epsilon_2(j - 1))(\epsilon_1(\lambda'_j - i + 1) - \epsilon_2(\lambda_i - j))}.
$$

(4.10)

### 4.1 First expansion coefficient

Let us consider the following $A_2$-expansion:

$$
A^{(2)}(b_E q_2) := \left\langle \prod_{I=1}^{N_L} \exp \left( -\frac{(b_E q_2)^2}{w_I} \right) \right\rangle_{N_L}^\lambda \left\langle \prod_{J=1}^{N_R} \exp \left( -\frac{(b_E q_2)^2}{u_J} \right) \right\rangle_{N_R}^\lambda \left\langle \prod_{I=1}^{N_L} \prod_{J=1}^{N_R} \left( 1 - \frac{(b_E q_2)^2}{w_I u_J} \right) \right\rangle_{N_L'}^{N_L} \left\langle \sum_{J=1}^{N_R'} b_E^2 u_J \right\rangle_{N_R'}^\lambda
$$

$$
= 1 + \sum_{\ell=1}^{\infty} \Lambda_2^{2\ell} A^{(2)}_\ell.
$$

(4.11)

We have

$$
A^{(2)}_1 = -\frac{1}{g_s^2} \left\langle \sum_{I=1}^{N_L} b_E^2 \right\rangle_{N_L'}^{N_L} - \frac{1}{g_s^2} \left\langle \sum_{J=1}^{N_R} b_E^2 \right\rangle_{N_R'}^{N_R} - \frac{2}{g_s^2} \left\langle \sum_{I=1}^{N_L} b_E^2 \right\rangle_{N_L'}^{N_L} \left\langle \sum_{J=1}^{N_R} b_E^2 \right\rangle_{N_R'}^{N_R}.
$$

(4.12)

By using (3.17) and

$$
\left\langle \sum_{J=1}^{N_R} b_E^2 \right\rangle_{N_R'}^{N_R} = \frac{b_E N_R}{\bar{\alpha}_4} = -\frac{(a + m_3)}{(\epsilon + 2a)}.
$$

(4.13)

we find

$$
A^{(2)}_1 = \frac{(a + m_2)(a + m_3)}{2a(2a + \epsilon) g_s^2} + \frac{(a - m_2)(a - m_3)}{2a(2a - \epsilon) g_s^2},
$$

(4.14)

which is the first Nekrasov function for $SU(2)$ with $N_f = 2$.

### Acknowledgements

O. is supported in part by the Grant-in-Aid for Scientific Research (2054278) as well as JSPS Bilateral Joint Projects (JSPS-RFBR collaboration) from the Ministry of Education, Science and Culture, Japan.
A Generalization of Integral representation of Iguri

In this appendix, we obtain the analytic continuation of the Selberg average as multiple complex contour integrals where we can take our limits. We employ a method similar to that used in [43].

Firstly, we introduce some definitions. In this appendix, we study complex integrals along four paths specified at Fig.2 and Fig.3. The symbol $C$ denotes the contour shown in Fig.2 (left). The symbol $C_{[0,1]}$ stands for a path composed of the segments connecting $x = 0 \pm 0i$ and $x = 1 \pm 0i$. See Fig.2 (right). The symbol $\tilde{C}_\rho$ is defined by subtracting of $C_{[0,1]}$ from $C_\rho$: $\tilde{C}_\rho := C_\rho - C_{[0,1]}$. See Fig.3 (left). The symbol $\tilde{D}_\rho$ stands for a tadpole-type path specified at Fig.3 (right). Let us introduce a symbol representing an ordering along the path $C_\rho$ by $\preceq$. We mean by $x \preceq y$ that $y$ is ahead of $x$ along the path. To complete the definition of $\preceq$, we regard $1 - 0 - 0i$ and $1 + 0 - 0i$ as the starting point and the end point of $C_\rho$ respectively. The symbol $\Phi_{N}^{(n)}(\beta_1, \beta_2, \gamma; x)$ represents an integral kernel used in this appendix:

$$
\Phi_{N}^{(n)}(\beta_1, \beta_2, \gamma; x) := \left( \prod_{i=1}^{n} |x_i|^{\beta_1-1} |1-x_i|^{\beta_2-1} \right) \left( \prod_{i=n+1}^{N} (-x_i)^{\beta_1-1} (1-x_i)^{\beta_2-1} \right) \\
\times \left( \prod_{1 \leq i \leq n < j \leq N} \frac{1-x_i}{x_j} \right)^{2\gamma} \left( -x_j \right)^{2\gamma} \\
\times \left( \prod_{n+1 \leq i < j \leq N} \frac{1-x_i}{x_j} \right)^{2\gamma} \left( -x_j \right)^{2\gamma} \left( \prod_{1 \leq i < j \leq n} |x_i - x_j|^{2\gamma} \right)
$$

(A.1)

The reason why we employ the complicated term $(1 - \frac{x_i}{x_j})^{2\gamma} (-x_j)^{2\gamma}$ instead of $(x_i - x_j)^{2\gamma}$ is that this term has following good properties:

$$
\left( 1 - \frac{x}{y} \right)^{2\gamma} (-y)^{2\gamma} = e^{-2\gamma i} \left( 1 - \frac{y}{x} \right)^{2\gamma} (-x)^{2\gamma} \quad (2\pi > \text{Arg } x > \text{Arg } y \geq 0) \quad (A.2)
$$

$$
\left( 1 - \frac{x}{y} \right)^{2\gamma} (-y)^{2\gamma} = (x - y)^{2\gamma} \quad (x \in \mathbb{R}^+) \quad (A.3)
$$

Let $f(x) = f(x_1, x_2, \cdots, x_N)$ be a holomorphic function in the region excluding $x \in (1, +\infty)$ and be invariant under the permutations of $x_1, x_2, \cdots, x_N$. For the sake of convenience, we introduce the symbol $s(z)$ that stands for

$$
s(z) := \sin \pi z. \quad (A.4)
$$
Figure 2: $x_{n+1}$ plane is illustrated. The wiggly lines are cuts of $\Phi_N^{(0)}$ with $N = 3$. The left figure shows a contour $C_\rho$. Note that this contour does not get across the cuts of $\Phi_N^{(0)}$. We denote by $C_{[0,1]}$ the path appearing in the right figure.

Secondly, we show the following equations:

\[
\left( \prod_{I=1}^{N} \int_{\mathcal{C}_\rho} dx_I \right) \Phi_N^{(0)}(x)f(x) = \left( \prod_{I=1}^{N} e^{i\pi(g-I-N)} \frac{s(\gamma I)}{s(\gamma)} \right) \int_{1+0i \leq x_1 \leq \cdots \leq x_N \leq 1+0i} \left( \prod_{I=1}^{N} dx_I \right) \Phi_N^{(0)}(x)f(x) \tag{A.5}
\]

\[
\left( \prod_{I=1}^{N} \int_{C_{[0,1]}} dx_I \right) \Phi_N^{(0)}(x)f(x) = \left( \prod_{I=1}^{N} e^{i\pi(g-I-N)} \frac{s(\gamma I)}{s(\gamma)} \right) \int_{1+0i \leq x_1 \leq \cdots \leq x_N \leq 1-0i} \left( \prod_{I=1}^{N} dx_I \right) \Phi_N^{(0)}(x)f(x). \tag{A.6}
\]

Let $S_N$ be the symmetric group of degree $N$. We define the action of $\sigma \in S_N$ on a symmetric function $g(x)$ as follows:

\[
\sigma \cdot g(x_1, x_2, \cdots, x_N) = g(x_{\sigma(1)}, x_{\sigma(2)}, \cdots, x_{\sigma(N)}). \tag{A.7}
\]

The equation (A.5) can be written as

\[
\sum_{\sigma \in S_N} \int_{1+0i \leq x_1 \leq \cdots \leq x_N \leq 1+0-0i} \left( \prod_{I=1}^{N} dx_I \right) \sigma \cdot \Phi_N^{(0)}(x)f(x)
= \left( \prod_{I=1}^{N} e^{i\pi(g-I-N)} \frac{s(\gamma I)}{s(\gamma)} \right) \int_{1+0i \leq x_1 \leq \cdots \leq x_N \leq 1+0-0i} \left( \prod_{I=1}^{N} dx_I \right) \Phi_N^{(0)}(x)f(x). \tag{A.8}
\]
Figure 3: \( x_{n+1} \) plane is illustrated. The wiggly lines are cuts of \( \Phi_N^{(0)} \) with \( N = 3 \). A path \( \tilde{C}_\rho \) is illustrated in the left figure. This path is obtained by \( C_\rho - C_{[0,1]} \). A path \( \tilde{D}_\rho \) is illustrated in the right figure. As a matter of convenience, we introduce parameter \( z \). \( z + 0i \) and \( z - 0i \) are the starting point and the end point of \( \tilde{D}(\rho', z) \) respectively.

Let \( \rho_{i,j} \) be a transposition and \( \varpi_n \) be a cyclic permutation defined as follows:

\[
\rho_{i,j}(k) = \begin{cases} 
  j & (k = i) \\
  i & (k = j) \\
  k & (k \neq i, j) 
\end{cases} \quad (A.9)
\]

\[
\varpi_n(k) = \begin{cases} 
  k & (k < n) \\
  N + 1 & (k = n) \\
  k - 1 & (k > n) 
\end{cases} \quad (A.10)
\]

Note that

\[
\varpi_n = \rho_{N+1,N} \cdot \rho_{N,N-1} \cdots \rho_{n+1,n}. \quad (A.11)
\]

The eq. (A.2) implies

\[
\rho_{i,i+1} \cdot \Phi_N^{(0)}(x_1, x_2, \ldots, x_N) = e^{-2\pi\gamma i} \Phi_N^{(0)}(x_1, x_2, \ldots, x_N) \quad (1 + 0i \preceq x_1 \preceq \cdots \preceq x_N \preceq 1 + 0 - 0i). \quad (A.12)
\]
Furthermore, introduce
\[ S_{N+1}^N := \{ \sigma \in S_{N+1} | \sigma(N + 1) = N + 1 \}. \] (A.13)

Note that
\[ S_{N+1} = \bigcup_n (S_{N+1}^N \cdot \varpi_n) \] (A.14)
\[ \emptyset = (S_{N+1}^N \cdot \varpi_i) \cap (S_{N+1}^N \cdot \varpi_j) \quad (i \neq j), \] (A.15)

where
\[ S_{N+1}^N \cdot \varpi_n = \{ \sigma \cdot \varpi_n \in S_{N+1}^N | \sigma \in S_{N+1}^N \}. \] (A.16)

Now, we employ the mathematical induction on \( N \) to show (A.5). If \( N = 2 \), (A.5) is obvious. Suppose that if \( N = k \), (A.5) is true. For \( N = k + 1 \), we obtain
\[
\sum_{\sigma \in S_{k+1}} \int_{1+0i \leq x_1 \leq \cdots \leq x_{k+1} \leq 1+0i} \left( \prod_{I=1}^{k+1} dx_I \right) \sigma \cdot \Phi_N^{(0)}(x) f(x)
\]
\[ = \sum_{n=1}^{k+1} \sum_{\sigma_k \in S_{k+1}^n} \int_{1+0i \leq x_1 \leq \cdots \leq x_{k+1} \leq 1+0i} \left( \prod_{I=1}^{k+1} dx_I \right) \sigma_k \cdot \varpi_n \cdot \Phi_N^{(0)}(x) f(x) \] (A.17)
\[ = \sum_{n=1}^{k+1} e^{-2\pi i (n-1)} \sum_{\sigma_k \in S_{k+1}^n} \int_{1+0i \leq x_1 \leq \cdots \leq x_{k+1} \leq 1+0i} \left( \prod_{I=1}^{k+1} dx_I \right) \sigma_k \cdot \Phi_N^{(0)}(x) f(x) \]
\[ = \left( \prod_{I=1}^{k+1} e^{i\pi (I-k)} \frac{s(\gamma I)}{s(\gamma)} \right) \int_{1+0i \leq x_1 \leq \cdots \leq x_{k+1} \leq 1+0i} \left( \prod_{I=1}^{k+1} dx_I \right) \Phi_N^{(0)}(x) f(x). \]

Thus, (A.5) is proven. The eq. (A.6) is shown by the same proof.

Thirdly, we show
\[
\left( \prod_{I=1}^{N} \int_0^1 dx_I \right) \Phi_N^{(N)}(x) f(x) = \left( \frac{i}{2} \right)^N \left( \prod_{I=1}^{N} \frac{e^{i\pi (I-k)}}{s(\beta + (N-I)\gamma)} \right) \left( \prod_{I=1}^{N} \int_{C_{\rho}} dx_I \right) \Phi_N^{(0)}(x) f(x). \] (A.18)

Now, we consider the case
\[
0 \leq x_1 \leq x_2 \cdots \leq x_n \leq 1 \] (A.19)
\[ 1 + 0i \leq x_{n+2} \leq \cdots \leq x_N \leq 1 + 0i \] (A.20)

The \( n \) points \( x_1, \cdots, x_n \) lie on the segments \( C_{[0,1]} \). Let us consider
\[
\int_{C_{\rho}} \Phi_N^{(n)}(\beta_1, \beta_2, \gamma; x) f(x) dx_{n+1}. \] (A.21)
This integral vanishes as there is no singularity in the region enclosed by this contour. Converting the integral over $C_{[0,1]}$ into that over the segment $(0, 1)$ on the real axis, we obtain

\[
0 = -\left[ e^{-i\beta_1} \left( \int_0^{x_1} + e^{-2i\pi\gamma} \int_{x_1}^{x_2} + e^{-4i\pi\gamma} \int_{x_2}^{x_3} + \cdots + e^{-2ni\pi\gamma} \int_{x_{n-1}}^{x_n} \right) \right.
- e^{i\beta_1} \left( \int_0^{x_1} + e^{2i\pi\gamma} \int_{x_1}^{x_2} + e^{4i\pi\gamma} \int_{x_2}^{x_3} + \cdots + e^{2ni\pi\gamma} \int_{x_{n-1}}^{x_n} \right) \right]
\times \Phi_N^{(n+1)}(\beta_1, \beta_2, \gamma; x) f(x) dx_{n+1}
+ \left( \int_{1+0i \leq x_{n+1} \leq x_{n+2}} + \cdots + \int_{x_N \leq x_{n+1} \leq 1-0i} \right) \Phi_N^{(n)}(\beta_1, \beta_2, \gamma; x) f(x) dx_{n+1}.
\]

Here, the phase factors appear due to the replacement $\Phi_N^{(n)} \rightarrow \Phi_N^{(n+1)}$.

Let us integrate the above expression over $x_1, \cdots, x_n, x_{n+2}, \cdots, x_N$, keeping the ordering $A.19$ and $A.20$. In this formula, the integrals over the real axis can be converted into those over the region $0 \leq x_1 \leq \cdots \leq x_{n+1} \leq 1$ and $1 + 0i \leq x_{n+2} \leq \cdots \leq x_N \leq 1 + 0 - 0i$ by the appropriate interchange of $x_I$'s. The remaining integrals can also be converted into those over the region $0 \leq x_1 \leq \cdots \leq x_n \leq 1$ and $1 + 0i \leq x_{n+1} \leq \cdots \leq x_N \leq 1 + 0 - 0i$. We obtain

\[
-\frac{2is((n+1)\gamma)s(\beta_1 + n\gamma)}{s(\gamma)} \int_{0 \leq x_1 \leq \cdots \leq x_{n+1} \leq 1} \prod_{I=1}^{N} dx_I \Phi_N^{(n+1)}(\beta_1, \beta_2, \gamma; x) f(x)
= \int_{0 \leq x_1 \leq \cdots \leq x_n \leq 1} \prod_{I=1}^{N} dx_I \Phi_N^{(n)}(\beta_1, \beta_2, \gamma; x) f(x),
\]

where we use the following formula:

\[
\sum_{j=0}^{n} s(\beta_1 + 2j\gamma) = s((n+1)\gamma) s(\beta_1 + n\gamma).
\]

Using $A.23$ repeatedly and $A.5$, we obtain $A.18$.

Fourthly, we show

\[
\left( \prod_{I=1}^{N} \int_{0}^{1} dx_I \right) \Phi_N^{(N)}(x) f(x) = \left( -\frac{i}{2} \right)^N \left( \prod_{I=1}^{N} \frac{e^{i\pi\gamma(N-I)}}{s(\beta + (N-I)\gamma)} \right) \left( \prod_{I=1}^{N} \int_{c_{[0,1]}} dx_I \right) \Phi_N^{(0)}(x) f(x).
\]

Consider

\[
\int_{C_{0}} \Phi_N^{(0)}(\beta_1, \beta_2, \gamma; x) f(x) dx_{n+1}.
\]

(A.26)
with the ordering \((A.20)\) and
\[
1 + 0i \succeq x_1 \succeq \cdots \succeq x_N \succeq 1 - 0 - 0i.
\](A.27)

We follow the proof of \((A.18)\) but this time not converting the integral over \(C_{[0,1]}\) into that over the segment \((0,1)\) on the real axis. By using \((A.5)\) and \((A.6)\), we obtain
\[
\left( \prod_{I=1}^{N} \int_{C_{[0,1]}} dx_I \right) \Phi_N^{(0)}(x) f(x) = (-1)^N \left( \prod_{I=1}^{N} \int_{C_{[0,1]}} dx_I \right) \Phi_N^{(0)}(x) f(x). \tag{A.28}
\]

Now, we derive \((A.25)\) from \((A.18)\).

Fifthly, we prove
\[
\left( \prod_{I=1}^{N} \int_{0}^{1} dx_I \right) \Phi_N(\beta_1, \beta_2, \gamma; x) f(x) = \left( \frac{i}{2} \right)^N \left( \prod_{I=1}^{N} \frac{e^{i\pi\gamma(I-N)}}{s(\beta + (N-I)\gamma)} \right) \times \left( \prod_{I=1}^{N} \int_{\tilde{D}(1/\rho,1)} dx_I \right) \Phi_N^{(0)}(1 - \beta_1 - \beta_2 - 2(N-1)\gamma, \beta_2, \gamma; x)f\left(\frac{1}{x}\right). \tag{A.29}
\]

By the transformation \(x \to 1/x\), we obtain
\[
\left( \prod_{I=1}^{N} \int_{0}^{1} dx_I \right) \Phi_N(\beta_1, \beta_2, \gamma; x) f(x) = \left( \prod_{I=1}^{N} \int_{\tilde{D}(1/\rho,1)} dx_I \right) \Phi_N(1 - \beta_1 - \beta_2 - 2(N-1)\gamma, \beta_2, \gamma; x)f\left(\frac{1}{x}\right), \tag{A.30}
\]

where \(f\left(\frac{1}{x}\right)\) is obtained by replacing \(x_I\) by \(1/x_I\) in \(f(x)\) and \(\tilde{D}(1/\rho,z)\) is defined by Fig.3. In obtaining the above equation, we have used \((A.3)\) with \(x = 1\) and convert the variable \(x_I\) to \(x_{N+1-I}\). By using \((A.18)\), we have \((A.29)\). Notice that this formula holds independently of the radius parameter \(\rho\).

Let us consider the limit of \((A.29)\) as \(1/\rho \to 0\). Then, \(\tilde{D}(1/\rho,1)\) reduce to \(-C_{[0,1]}\). Suppose that \(f(1/x)\) is holomorphic function at \(x \in (0,1)\). Then, we can apply \((A.25)\) to \((A.29)\) and obtain
\[
\left( \prod_{I=1}^{N} \int_{0}^{1} dx_I \right) \Phi_N(\beta_1, \beta_2, \gamma; x) f(x) = C_N(\beta_1, \beta_2, \gamma) \left( \prod_{I=1}^{N} \int_{0}^{1} dx_I \right) \Phi_N^{(0)}(1 - \beta_1 - \beta_2 - 2(N-1)\gamma, \beta_2, \gamma; x)f\left(\frac{1}{x}\right), \tag{A.31}
\]

where
\[
C_N(\beta_1, \beta_2, \gamma) := \prod_{I=1}^{N} \frac{s(\beta_1 + \beta_2 + (2N-I-1)\gamma)}{s(\beta_1 + (N-I)\gamma)}. \tag{A.32}
\]

The above formula has been shown by Iguri [43].
