NUMERICAL INVESTIGATION OF FREE CONVECTION OVER A PERMEABLE HORIZONTAL FLAT PLATE EMBEDDED IN A POROUS MEDIUM WITH RADIATION EFFECTS AND MIXED THERMAL BOUNDARY CONDITIONS

MOHD ZUKI SALLEH*, NAJIHAH MOHAMED1, ROZIEANA KHAIRUDDIN1, NAJIYAH SAFWA KHASI'TE1 & ROSLINDA NAZAR2

ABSTRACT

In this paper, the mathematical modelling of free convection boundary layer flow over a permeable horizontal flat plate embedded in a porous medium under mixed thermal boundary conditions and radiation effects, is considered. The transformed boundary layer equations are solved numerically using the shooting method. Numerical solutions are obtained for the wall temperature, the heat transfer coefficient, as well as the velocity and temperature profiles. The features of the flow and heat transfer characteristics for different values of the radiation parameter \( R_N \), the mixed thermal boundary condition parameter \( \varepsilon \) and the suction or injection parameter \( \gamma \) are analyzed and discussed.

Keywords: free convection; mixed thermal boundary conditions; permeable horizontal flat plate; porous medium; radiation

1. Introduction

The transport properties of fluid-saturated porous materials are due to the increasing number of important applications in many modern industries, ranging from heat removal processes in engineering technology and geophysical problems. Further examples of convection through porous media may be found in manmade systems such as granular insulations, winding structures for high-power density electric machines, and the cores of nuclear reactor (Bejan 1984; Pop & Ingham 2001; Nield & Bejan 2006).

Following Pop and Ingham (2001), Cheng and Chang (1976) were probably the first to consider the similarity solutions for the free convection boundary layer flow about a heated horizontal impermeable surface embedded in a porous medium, where the surface temperature is a power function of the distance from the origin. In a subsequent paper, Chang and Cheng (1983) pointed out that this boundary layer approximation is identical to the governing equations for the first order inner problem in a matched asymptotic expansion in which other effects, such as fluid entrainment, were taken into consideration. The free convection over an impermeable horizontal flat plate embedded in a porous medium has been discussed by many researchers such as Hsu et al. (1978), Ingham et al. (1985), Nazar et al. (2006), Moghaddam et al. (2009), etc. For permeable surfaces, Chaudhary et al. (1996) studied the natural convection from a horizontal permeable surface in a porous medium. Results obtained from various asymptotic analyses are found to compare well with those obtained from the direct numerical integration of the equations.

Radiation effects on free convection flow are important in the context of space technology and processes involving high temperature, and very little is known about the effects of radiation on the boundary-layer flow of a radiating fluid past a body. The inclusion of radiation effects in the energy equation, however, leads to a highly nonlinear partial
differential equation (Hossain et al. 2001). Hossain et al. (1999, 2001) have studied the effects of radiation on free convection from a porous vertical plate with a uniform surface temperature, a uniform rate of suction and with variable viscosity, respectively. Recently, Cortell (2008a, 2008b) separately studied radiation effects on Blasius and Sakiadis flows when the plate is maintained at a constant temperature and conjugate boundary conditions, respectively. He determined the effects of physical parameters like Prandtl number Pr and radiation parameter $N_R$ on the heat transfer characteristics. The previous studies of the free convection boundary layer flow over horizontal surfaces embedded in a porous medium dealt with numerical solutions associated with either prescribed/constant surface temperature or heat flux. Ramanaiah and Malarvizhi (1992) were the first to consider free convection adjacent to a wedge and a cone that are subjected to mixed thermal boundary conditions. Nazar et al. (2006) studied the free convection boundary layer flow over vertical and horizontal surfaces in a porous medium with mixed thermal boundary conditions. Laminar free convection flow about a wedge, a cone and a vertical spinning cone under mixed thermal boundary conditions and magnetic field were solved numerically using the Thomas algorithm by Ece (2005, 2009), respectively.

The aim of the study is to study the radiation effects of free convection boundary layer flow over a horizontal flat plate embedded in a porous medium under mixed thermal boundary conditions.

2. Analysis

Consider the steady free convection from a horizontal flat plate embedded in a fluid-saturated porous medium of uniform temperature $T_e$. Dimensional coordinates are used with $x$-axis measured along the surface and $y$-axis being normal to it. The boundary layer equations which govern the steady free convection flow over a horizontal surface which is embedded in a fluid-saturated porous medium are of the form (Pop & Ingham 2001):

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$  \hspace{1cm} (1)

$$\frac{\partial u}{\partial y} - \frac{gK \beta \partial T}{\nu} = 0$$  \hspace{1cm} (2)

$$\frac{\partial T}{\partial x} + \nu \frac{\partial^2 T}{\partial y^2} = \frac{1}{\rho c_p} \frac{\partial q_e}{\partial y} - \frac{1}{\rho c_p} \frac{\partial T}{\partial y},$$  \hspace{1cm} (3)

where $x$ and $y$ are the Cartesian coordinates with $x$-axis measured along the horizontal plate and $y$-axis is the coordinate normal to the plate, $\nu$ is the kinematic viscosity, $g$ is the gravitational acceleration, $\beta$ is the thermal expansion coefficient of the fluid, $K$ is the permeability of the saturated porous medium, $T$ is the temperature across the thermal boundary layer, $T_e$ is the constant temperature of ambient fluid, $\alpha_m = k/\rho c_p$ is the effective thermal diffusivity, $k$ is the thermal conductivity, $\rho$ is the fluid density and $c_p$ is the specific heat of the fluid at constant pressure.

We shall solve Eqs. (1)-(3) assuming that the boundary conditions for the velocity components $u$ and $v$ along with the mixed thermal and concentration boundary conditions are
Free convection over a permeable horizontal flat plate with mixed thermal boundary conditions

\[
\nabla(\overline{x},0) = v_m(\overline{x}), \quad A(\overline{x})T(\overline{x},0) - B(\overline{x})\frac{\partial T}{\partial \overline{y}}|_{\overline{y}=0} = C_i(\overline{x})
\]

\[
T(\overline{x},\overline{y}) \rightarrow T_\infty, \quad \text{as} \quad \overline{y} \rightarrow \infty
\]

where \(v_m(\overline{x})\) is the mass transfer velocity with \(v_m(\overline{x}) > 0\) when fluid is injected into the flow from the wall and \(v_m(\overline{x}) < 0\) when fluid is removed through the wall. Let \(A(\overline{x})\), \(B(\overline{x})\) and \(C(\overline{x})\) be the undetermined functions of \(\overline{x}\).

Using the Rosseland approximation for radiation (Bataller 2008), the radiative heat flux is simplified as

\[
q_r = -\frac{4\sigma^*}{3k^*} \frac{\partial T^4}{\partial \overline{y}}
\]

where \(\sigma^*\) and \(k^*\) are the Stefan-Boltzmann constant and the mean absorption coefficient, respectively. We assume that the temperature differences within the flow through the porous medium such as that the term \(T^4\) may be expressed as a linear function of temperature.

Hence, expanding \(T^4\) in a Taylor series about \(T_\infty\) and neglecting higher-order terms, we get

\[
T^4 \approx 4T_\infty^3 (T - T_\infty)
\]

In view of Eqs. (5) and (6), Eq. (3) reduces to

\[
\overline{u} \frac{\partial T}{\partial \overline{x}} + v \frac{\partial T}{\partial \overline{y}} = \left(\frac{\alpha_m + 16\sigma^* T_\infty^3}{3\rho C_p k^*}\right) \frac{\partial^2 T}{\partial \overline{y}^2}
\]

From this equation it is seen that the effect of radiation is to enhance the thermal diffusivity.

Following Bataller (2008), we take \(N_R = k k^*/(4\sigma^* T_\infty^3)\) as the radiation parameter, so that Eq. (7) becomes

\[
\overline{u} \frac{\partial T}{\partial \overline{x}} + v \frac{\partial T}{\partial \overline{y}} = \frac{\alpha_m}{k_0} \frac{\partial^2 T}{\partial \overline{y}^2}
\]

where the dimensionless parameter \(k_0\) is defined as

\[
k_0 = \frac{3N_R}{3N_R + 4}
\]

Further, we introduce now, the following dimensionless variables:

\[
x = \overline{x}/L, \quad y = Ra^{-1/3} (\overline{y}/L), \quad u = Ra^{-2/3} (L/\alpha_m)\overline{u}
\]

\[
v = Ra^{-1/3} (L/\alpha_m)\overline{v}, \quad \theta = (T - T_\infty)/(T_r - T_\infty)
\]

where \(T_r\) is the reference temperature and \(Ra = \rho \beta (T_r - T_\infty) L/\alpha_m\) \(v\) is the Rayleigh number for a porous medium. Thus, Eqs. (1), (2) and (8) can be written as

\[
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0
\]

\[
\frac{\partial u}{\partial y} = - \frac{\partial \theta}{\partial x}
\]

\[
u \frac{\partial \theta}{\partial x} + \frac{\partial \theta}{\partial y} = \frac{1}{k_0} \frac{\partial^2 \theta}{\partial y^2}
\]

and the boundary conditions (4) become
We look for a similarity solution of Eqs. (11)-(13) of the following form:
\[ \psi = x^{1/3} f(\eta), \quad \theta = \theta(\eta), \quad \eta = y / x^{2/3} \]  
(15)
where \( \psi \) is the stream function defined in the usual way as \( u = \partial \psi / \partial y \) and \( v = -\partial \psi / \partial x \).

In order that this similarity solution exists, we assume that \( J \) is for injection and \( 0 \) is for withdrawal of fluid. Substituting (15) into Eqs. (12) and (13), we obtain the following ordinary differential equations
\[ f'' - \frac{2}{3} \eta f' = 0 \]  
(16)
\[ \theta'' + \frac{1}{3} k f \theta' = 0 \]  
(17)
where primes denote differentiation with respect to \( \eta \). It is worth mentioning here that when \( k_0 = 1 \), the thermal radiation effect is not considered. The boundary conditions (14) reduce to
\[ f(0) = -\gamma, \quad a(x)(T_r - T_\infty)\theta(0) - b(x)(T_r - T_\infty)^{1/3} \theta'(0) = 1 \]  
\[ f'(\infty) \to 0, \quad \theta(\infty) \to 0 \quad \text{as} \quad \eta \to \infty \]  
(18)
where
\[ a(x) = \frac{A(x)}{C(x)} , \quad b(x) = \frac{B(x)}{C(x)} x^{-2/3} \left( \frac{g K \beta}{\alpha_m v L} \right)^{1/3} \]  
(19)
Each of these functions \( a(x) \) and \( b(x) \) must be equal to a constant to enable a similarity solution. For given values of the constants \( a, b \) and \( T_\infty \), the reference temperature \( T_r \) may be chosen to satisfy the following equation without any loss of generality
\[ a(T_r - T_\infty) + b(T_r - T_\infty)^{4/3} = 1 \]  
(20)
by defining \( \varepsilon = b(T_r - T_\infty)^{4/3} \), the thermal boundary condition (18) can be written as
\[ (1 - \varepsilon) \theta(0) - \varepsilon \theta'(0) = 1 \]  
(21)
It is worth noticing that the case \( \varepsilon = 0 \) corresponds to the constant surface temperature (CWT) \( \theta(0) = 1 \), the case \( \varepsilon = 1 \) corresponds to the constant surface heat flux (CHF) \( \theta'(0) = -1 \) and the case \( \varepsilon = \infty \) corresponds to the mixed thermal boundary conditions (MBC).

3. Results and Discussion

Equations (16) and (17) subjected to boundary conditions (18) are solved numerically using the shooting method for the cases of CWT when \( \xi = 0 \), CHF when \( \xi = 1 \) and MBC when \( \xi = \infty \). Values of \( \gamma \) considered are \( \gamma = -1 < 0 \) (suction), \( \gamma = 0 \) (impermeable wall) and \( \gamma = 1 > 0 \) (injection).

| 10    | 0.5771                 | 0.4121                        | 0.2834                 |
| 100   | 0.6138                 | 0.4278                        | 0.2854                 |
| 1000  | 0.6180                 | 0.4295                        | 0.2855                 |

Table 1 shows the numerical values of $-\theta'(0)$ when $\xi = 0$ (CWT case) with $\gamma = 0$ and $k_0 = 1$, where the thermal radiation effect is not considered. Numerical result obtained by an implicit finite-difference scheme as reported by Chang and Cheng (1983) for the case of CWT is included in this table for comparison purposes. It is found that the agreement between the previously published result with the present one is very good. We can conclude that this numerical method works efficiently for the present problem and we are also confident that the results presented here are accurate.

Values of $-\theta'(0)$ for various values of $N_R$ when $\xi = 0$ (for the case of CWT) and $\gamma = -1$, 0 and 1 are presented in Table 2. It is observed that $-\theta'(0)$ increases with increasing the radiation parameter $N_R$ for all cases of $\gamma = -1$, 0 and 1. When $N_R$ is fixed, it can be seen that $-\theta'(0)$ is higher for $\gamma = -1 < 0$ (suction) rather than those for $\gamma = 0$ and $\gamma = 1 > 0$ (injection).

Table 3 presents the values of $\theta(0)$ for various values of $N_R$ when $\xi = 1$ (for the case of CHF) and $\gamma = -1$, 0 and 1. It is found that $\theta(0)$ decreases with increasing the radiation parameter $N_R$ for all cases of $\gamma = -1$, 0 and 1. For fixed $N_R$, it can be seen that $\theta(0)$ is lower for $\gamma = -1 < 0$ (suction) rather than those for $\gamma = 0$ and $\gamma = 1 > 0$ (injection).
Table 3: Values of $\theta(0)$ for various values of $N_R$ when $\xi = 1$ (CHF) and $\gamma = -1, 0$ and 1

| 1     | 23.3410                  | 29.3049                        | 35.8520                  |
| 3     | 12.3566                  | 18.1411                        | 24.8680                  |
| 7     | 9.2675                   | 14.9515                        | 21.7791                  |
| 10    | 8.5786                   | 14.1338                        | 21.9904                  |
| 100   | 7.1427                   | 12.7267                        | 19.5120                  |
| 1000  | 7.0000                   | 12.5760                        | 19.5120                  |

Table 4 presents the values of $\theta(0)$ for various values of $N_R$ when $\xi = \infty$ (MBC) and $\gamma = -1, 0$ and 1. It is found that $\theta(0)$ decreases with increasing the radiation parameter $N_R$ for all cases of $\gamma = -1, 0$ and 1. For fixed $N_R$, it can be seen that $\theta(0)$ is lower for $\gamma = -1 < 0$ (suction) rather than those for $\gamma = 0$ and $\gamma = 1 > 0$ (injection).

The trend for MBC case is similar to the CHF case but different from the CWT case. It is worth mentioning that the numerical values given in Tables 1 to 4 are very important and they serve as a reference against which other exact or approximate solution can be compared in the future.

Figures 1 and 2 illustrate the velocity and temperature profiles when $N_R = 10$ and $\xi = \infty$ (MBC), respectively. These figures show that the values of $f'(\eta)$ and $\theta(\eta)$ decrease from 1 to 0 as $\eta$ increases from zero at different values of $\gamma$. Also, it is noticed that as $\gamma$ decreases, both the velocity and temperature profiles decrease and also the thermal boundary layer thickness decreases.
Free convection over a permeable horizontal flat plate with mixed thermal boundary conditions

Figure 1: Velocity profiles when $N_r =10$ and $\xi = \infty$ (MBC case).

Figure 2: Temperature profiles when $N_r =10$ and $\xi = \infty$ (MBC case).

4. Conclusion

In this paper, we have numerically studied the problem of free convection over a permeable horizontal flat plate embedded in a porous medium under mixed thermal boundary conditions with thermal radiation effect. We can conclude that when $\gamma$ is fixed, an increase in the radiation parameter $N_r$ leads to the increase of $-\theta'(0)$ (for the case of CWT). But, when $\gamma$ is fixed, an increase in the radiation parameter $N_r$ leads to the decrease of $\theta(0)$ (for both cases of CHF and MBC).
