Cataract Surgery and Visual Acuity in Elderly Japanese: Results of Fujiwara-kyo Eye Study

Kimie Miyata, Tadanobu Yoshikawa, Masashi Mine, Tomo Nishi, Nozomi Okamoto, Tetsuo Ueda, Ryo Kawasaki, Norio Kurumatani, and Nahoko Ogata

Abstract
The aim of this study was to determine the presence of prior cataract surgery and best-corrected visual acuity (BCVA) in an elderly Japanese cohort. The Fujiwara-kyo Eye Study was a prospective, population-based, cross-sectional epidemiological study. The subjects were ≥68 years who lived in the Nara Prefecture and responded to recruitment notices. All of the subjects underwent comprehensive ophthalmological examinations, and the sociodemographic information and medical history, including prior cataract surgery, were obtained by answers to a questionnaire. The associations between the BCVA, age, sex, and history of cataract surgery were determined. A total of 2,873 subjects whose mean age was 76.3 ± 4.9 (mean ± standard deviation) years were studied. The mean BCVA was 0.020 ± 0.14 logarithm of the minimum angle of resolution units, and it was significantly better in the group with education ≥13 years (p < 0.01). Overall, 24.2% of the subjects had undergone cataract surgery, and 41.7% of the subjects ≥80 years had undergone cataract surgery. The incidence of prior cataract surgery increased with increasing age (p < 0.001 for trend). The mean BCVA of eyes with cataract surgery was significantly better than that of eyes without cataract surgery in subjects ≥80 years (p < 0.01). Visual acuity was generally good in this cohort of elderly Japanese subjects. In this cohort, 24.2% of the subjects had undergone cataract surgery, and the subjects ≥80 years had better BCVA than those without cataract surgery.

Keywords: cataract; cataract surgery; cohort study; Fujiwara-kyo; visual acuity

Introduction
The age of individuals in developed countries is rapidly increasing, and Japan has become a superaged society. The average life span of men in Japan was 80.50 years and that of women was 86.83 years in 2014, which was one of the leading life spans in the world as reported by the Ministry of Health, Welfare, and Labour in Japan (www.mhlw.go.jp/toukei/saikin/hw/life/life13/index.html). According to an estimate by the Cabinet Office of Japan (www8.cao.go.jp/kourei/whitepaper/w-2015/gaiyou/27pdf_indexg.html), the proportion of people aged ≥65 years was 26.5% and that of people ≥75 years was 12.5% in 2014. The proportions are estimated to increase to 31.6% and 19.5%, respectively, in 2030.

To maintain a good quality of life (QOL), individuals must retain good physical and mental health. Vision is an important factor that can help maintain a good QOL in elderly subjects. An earlier study showed that subjects with good visual acuity after cataract surgery had not only a better QOL but also a longer life expectancy. Although several epidemiological surveys have been conducted to determine the visual function in the general population, there is still a lack of data on the elderly populations, especially those over 70 years. The Fujiwara-kyo Study is a cohort study that was begun in 2007 and was conducted to investigate the functional capacities and the QOL of elderly subjects in a community in Nara, Japan. As a part of the...
Fujiwara-kyo Study, we began an ophthalmological survey in 2012, named the Fujiwara-kyo Eye Study, to determine the influence of visual acuity on the functional daily activities and on the QOL.

The purpose of this study was to determine the best-corrected visual acuity (BCVA) and factors associated with BCVA in an elderly cohort. We also determined the relationship between visual acuity and the history of cataract surgery because cataract is the most common eye disorder of the elderly.3,12–15

**Subjects and Methods**

**The Fujiwara-kyo Study**

A detailed description of the Fujiwara-kyo Study has been reported.9–11 Briefly, this was a cohort study whose purpose was to identify factors related to the maintenance of a healthy life, prevention of physical weakness, and improvement of the functional capacities and the QOL of an elderly population in Japan.9–11 The Fujiwara-kyo Study was initially performed in 2007 on 4,427 individuals. The subjects consisted of residents in Nara Prefecture who were ≥65 years and living independently in their own homes. Nara Prefecture is located in the Western part of Japan and is a suburban city. The population of Nara Prefecture is 1.4 million people.

**The Fujiwara-kyo Eye Study**

An ophthalmological examination was not conducted in the initial survey in 2007, and an ophthalmological survey (Fujiwara-kyo Eye Study) was conducted for the first time during the second survey between February and November 2012. The second survey of Fujiwara-kyo Eye Study invited 2,873 subjects, including 80 newly recruited volunteers who were ≥65 years. The data presented in this article were collected in 2012. The subjects recruited at the initial survey in 2007 were ≥65 years and were 5 years older in 2012. There were 80 newly recruited subjects in 2012 who were ≥65 years.

The surveys were conducted in accordance with the tenets of the Declaration of Helsinki, and the protocol was approved by the Ethics Review Board of Nara Medical University. A signed informed consent form was obtained from all participants.

**Ophthalmological examinations**

**Self-administered ophthalmological questionnaires.** A history of cataract surgery was determined by a self-administered questionnaire. The eyes were divided into those with prior cataract surgery and those without. The subjects who had undergone cataract surgery in at least one eye were placed in the cataract surgery group for the individual analyses. Two hundred four randomly selected participants were examined by slit lamp to verify the accuracy of self-administered questionnaires regarding cataract surgery. For this, we checked the status of the lens or the intraocular lens to confirm an agreement with the self-administered questionnaires. The Kappa coefficient between self-administered questionnaires and diagnosis based on the slit lamp examination was high at 0.95.

**Visual acuity.** The uncorrected and corrected visual acuities of both eyes were measured with a Landolt ring chart at 5 m. The refractive errors were determined by an autorefractometer and keratometer (ARK-700A; Nidek, Gamagori, Japan). The visual acuity was measured according to the standard of the International Organization for Standardization.16 The decimal BCVA was converted to the logarithm of the minimum angle of resolution (logMAR) units for statistical analyses. To describe the age-specific BCVA, subjects were divided into five age groups, viz., ≤74 years, 75–79 years, 80–84 years, 85–89 years, and ≥90 years.

Subjects with a BCVA of <20/40 (>0.3 logMAR units) in the better seeing eye, the criterion of vision reduction used in the Blue Mountains Eye Study,7 was classified as being visually impaired. Blindness was defined as a BCVA in the better seeing eye of <3/60 based on the World Health Organization standards.

**Statistical analyses**

The significance of the differences in age and BCVA between sexes was tested by unpaired t tests as they were considered to be normally distributed. The significance of the differences in the number of eyes or subjects with Snellen visual acuity <20/40 in men and women was determined by chi-square tests. The BCVA of the different ages was analyzed by linear regression analysis. The associations between BCVA and the sociodemographics and health characteristics of the subjects were analyzed by unpaired t tests. The age-adjusted mean of BCVA was analyzed by analysis of covariance. The percentage of subjects with cataract surgery in the groups as a function of age was analyzed by linear regression analysis. The BCVA of eyes with and without cataract surgery in groups classified by age was analyzed by unpaired t tests. The differences of the sociodemographic and health characteristics of
individuals with and without cataract surgery were analyzed by chi-square and unpaired t tests. Statistical analyses were performed with SPSS (version 22.0; SPSS, Inc., Chicago, IL). A \( p < 0.05 \) was taken to be significant.

**Results**

A total of 2,873 subjects with a mean age of 76.3 ± 4.9 years (range 68–100 years) were studied in the Fujiwara-kyo Eye Study. There were 1,514 men (52.6%) whose mean age was 76.5 ± 4.9 (mean ± standard deviation) years and 1,359 women (47.3%) whose mean age was 76.0 ± 4.8 years. The mean BCVA of the better eye of the 2,873 subjects was −0.020 ± 0.14 logMAR units, of the men was −0.028 ± 0.13 logMAR units, and that for the women was −0.010 ± 0.14 logMAR units. The BCVA was significantly better in men than in women (\( p < 0.01 \); Table 1). A visual impairment of the better eye was observed in 97 of the 2,873 subjects (3.4%; Table 1), and the incidence was significantly higher in women than in men (\( p < 0.01 \); Table 1). None of the subjects were classified as being blind according to our definition.

**Visual acuity by age groups**

The subjects were divided into five groups by age. The mean BCVA was −0.049 ± 0.13 logMAR units in those \( \leq 74 \) years, −0.014 ± 0.13 logMAR units in the 75–79-year group, 0.012 ± 0.13 logMAR units in the 80–84-year group, 0.039 ± 0.16 logMAR units in the 80–84-year group, and 0.081 ± 0.15 logMAR units in the ≥90-year group. Linear regression analyses showed that BCVA was significantly worse in the older subjects (\( p < 0.01 \) for trend; Fig. 1). The BCVA was 0.021 ± 0.14 logMAR units in those aged ≥80 years (701 subjects).

**Population of subjects with prior cataract surgery by age**

The history of cataract surgery was not obtained from 47 subjects because of a failure to answer the questions or failure to be recorded. There were 685 subjects (24.2%) in the prior cataract surgery group and 2,141 subjects (75.8%) in the no cataract surgery group (Table 4). The percentage of subjects who had undergone cataract surgery was 14.7% in the \( \leq 74 \) year group, 23.3% in the 75–79-year group, 34.0% in the 80–84-year group, 61.5% in the 85–90-year group, and 61.5% in the ≥90-year group. The percentage of subjects who had undergone cataract surgery increased with age (\( p < 0.01 \) for trend; Fig. 2), and 41.7% of subjects aged ≥80 years had had cataract surgery.

**Correlations between BCVA and the socio-demographics and health characteristics**

The mean BCVA of the better-seeing eye was significantly better in the group with ≥13 years of education

---

**Table 1. Basic Characteristics of 2,873 Subjects**

| Characteristics | All, \( n = 2,873 \) | Male, \( n = 1,514 \) | Female, \( n = 1,359 \) | \( p \) |
|-----------------|----------------------|----------------------|----------------------|------|
| Age, mean ± SD, years | 76.3 ± 4.9 | 76.5 ± 4.9 | 76.0 ± 4.8 | <0.05 |
| BCVA of better seeing eye, mean ± SD, LogMAR units | –0.020 ± 0.14 | –0.028 ± 0.13 | –0.010 ± 0.14 | <0.01 |
| BCVA ≥0.3 LogMAR units, number of subjects (%) | 97 (3.4) | 36 (2.4) | 61 (4.5) | <0.01 |

BCVA, best-corrected visual acuity; logMAR, logarithm of the minimum angle of resolution; SD, standard deviation.
than that in the group with ≤12 years of education (BCVA, \(-0.039±0.14\) vs. \(-0.015±0.13\) logMAR units, \(p<0.01\); Table 2). The differences were still significant when they were adjusted by age (\(p<0.01\); Table 2).

**BCVA of eyes with and without cataract surgery in age groups**

The differences in BCVA between eyes with prior cataract surgery and without cataract surgery were not significant in groups under 80 years. However, the eyes of subjects ≥80 years who had undergone cataract surgery had better BCVA compared with eyes without cataract surgery (\(p<0.01\); Table 3).

**Sociodemographic characteristics and cataract surgery**

The incidence of prior cataract surgery in men was significantly lower than that of women (\(p<0.01\); Table 4). The percentage and odds ratio (OR) of subjects with prior stroke or had hypertension and diabetes mellitus were higher in subjects who had prior cataract surgery (\(p<0.02\), OR 1.47, \(p<0.04\), OR 1.20, and \(p<0.01\), OR 1.40, respectively; Table 4). The prevalence of prior cataract surgery was not significantly associated with the duration of education.

**Discussion**

The mean BCVA of \(-0.020±0.14\) logMAR units for all of the participants indicated that the visual acuity was generally good in this elderly cohort. There were only 3.4% of participants with a visual impairment defined as having a fully corrected Snellen visual acuity of <20/40 (>0.3 logMAR units). The BCVA was significantly worse in the older subjects. The prevalence of

| Hypertension (% of subjects)    | \(-0.020±0.13\) (51.8)         | \(-0.021±0.14\) (48.2)          | 0.9   | \(-0.022\)                      | \(-0.018\)                     | 0.4   |
| Diabetes mellitus (% of subjects) | \(-0.011±0.13\) (15.0)     | \(-0.022±0.14\) (85.0)          | 0.2   | \(-0.011\)                      | \(-0.022\)                     | 0.14  |

BMI, body–mass index.
visual impairments (visual acuity <20/40) in the better eye was 12.3% for those ≥55 years in the Blue Mountains Eye Study\textsuperscript{17} and it was 27.8% in the ≥80-year group in the Los Angeles Latino Eye Study.\textsuperscript{18} Compared with these figures, it is noteworthy that a mean BCVA of 0.021 logMAR units in subjects ≥80 years is relatively good as has been reported in an earlier study on Japanese individuals.\textsuperscript{19}

It is interesting that the BCVA adjusted by age was significantly better in subjects with education ≥13 years than with ≤12 years of education. A recent study reported that the prevalence of any visual impairment (Snellen visual acuity <20/40) was two times higher in the lower socioeconomic group.\textsuperscript{20} Our data are in agreement with these results if we assume that a shorter education time reflects a lower socioeconomic status.

The sociodemographic and health characteristics of the subjects who had undergone cataract surgery have been reported.\textsuperscript{5,21,22} In this study, the subjects who had prior cataract surgery were significantly older, were more likely to be women, and had a higher incidence of stroke, hypertension, and diabetes than in subjects without prior cataract surgery. An earlier study reported that the subjects in the longer duration education group had a higher chance of having had cataract surgery;\textsuperscript{23} however, we did not find a significant association between the duration of education and a history of cataract surgery.

In our cohort, 24.2% had undergone cataract surgery, and almost twice as many subjects (41.7%) aged ≥80 years had undergone cataract surgery. The Singapore Epidemiology of Eye Disease Study reported that the prevalence of cataract surgery in people aged ≥80 years was 63.9% in the Chinese population, 38.89% in the Malaysian population, and 68.25% in the East Indian population.\textsuperscript{21} These observations are higher than that of the Blue Mountains Eye Study of 23% in the ≥80-year group.\textsuperscript{23} These differences may be due to the sociodemographic circumstances and the systems of health insurance.

Cataract surgery is performed more often in some countries and increasing trends of surgeries are observed in two populations.\textsuperscript{23,24} In the Blue Mountains Eye Study, there was a 32% increase in cataract surgery over a 6-year period from 1992–1994 to 1997–2000 with age-standardized prevalence of 6.0–7.7%. It was more marked among people ≥80 years old from 23.0% to 31.7%.\textsuperscript{23} It has been estimated that the number of subjects with cataract surgery has increased in the last decade reflecting continued aging of the population.\textsuperscript{24} In the United States, the incidence of lens extraction has also increased over the past 20 years in individuals older than 65 years.\textsuperscript{25} Japan has become a superaged society and our findings may reflect this situation, showing that cataract surgery is increasing even in those aged ≥80 years.

As expected, eyes with cataracts have greater improvement in visual acuity after cataract surgery.\textsuperscript{2,26} In our study, there was no significant difference of the mean BCVA between eyes with cataract surgery and in eyes without cataract surgery in relatively younger subjects of <79 years. However, the mean BCVA of eyes with prior cataract surgery was significantly better compared with eyes with no cataract surgery in subjects

### Table 4. Sociodemographic Data and Health Characteristics of Subjects with Cataract Surgery and with No Cataract Surgery

|                      | Cataract surgery no. of subjects (%) | No cataract surgery no. of subjects (%) | p     | OR    | 95% CI |
|----------------------|-------------------------------------|-----------------------------------------|-------|-------|--------|
| Age, mean ± SD, years| 78.8 ± 5.4                          | 75.5 ± 4.4                              | <0.01 | 2.63  | 2.17–3.19 |
| Gender, men          | 332 (48.5)                          | 1,155 (53.9)                            | 0.01  | 1.22  | 1.04–1.47 |

| Stroke, present      | 55 (8.0)                            | 120 (5.6)                               | 0.02  | 1.47  | 1.06–2.05 |
| Myocardial infarction, present | 26 (3.8)                          | 54 (2.5)                               | 0.09  | 0.65  | 0.41–1.65 |
| Angina, present      | 58 (8.5)                            | 175 (8.2)                               | 0.8   | 0.96  | 0.70–1.31 |
| Hypertension, present| 379 (55.3)                          | 1,087 (50.7)                            | 0.04  | 1.20  | 1.01–1.43 |
| Diabetes mellitus, present | 126 (18.4)                          | 298 (13.9)                             | <0.01 | 1.40  | 1.11–1.76 |

CI, confidence interval; OR, odds ratio.

≥80 years (p < 0.01). These results may indicate that relatively younger subjects are concerned about failing vision even if only slightly, and they undergo cataract surgery at an earlier age. Alternatively, subjects ≥80 years may not wish to undergo cataract surgery even if they have failing vision.

It has been reported that the life expectancy was longer in patients whose visual acuity was better after cataract surgery.3–5,27 We found in an earlier cross-sectional study that subjects with cataract surgery had significantly lower age-adjusted ORs for cognitive impairment than subjects without cataract surgery.28 In addition, we recently reported that subjects with visual impairment had twofold higher OR for the prevalence of cognitive impairment (Snellen visual acuity <20/20) than subjects without visual impairment.29 Thus, we believe that improvements of visual acuity after cataract surgery may have beneficial effects on both the QOL and longevity.

There are limitations in this study. Subjects were not randomly selected from the geographical area as it was based on participants who volunteered. Thus, there is a chance of introducing selection bias of having relatively healthier and more independent persons. In addition, the causes of visual impairment were not determined in detail. Because the primary aim of the Fujiwara-kyo Study was to survey the functional capabilities and QOL of independent elderly residents in a community, ophthalmological examinations were limited to determining only the visual functions in these elderly subjects.

In conclusion, we found that 1 in 4 (24.2%) of the subjects aged ≥68 years had undergone cataract surgery, and the subjects aged ≥80 years had better BCVA than those without cataract surgery. This study is the first to report the prevalence of cataract surgery in elderly subjects in a relatively large sample size in Japan. Future follow-up examinations will reveal the associations of visual functions, especially whether visual acuity contributes to maintain good QOL and healthy life expectancy.

Abbreviations Used

- BCVA = best-corrected visual acuity
- BMI = body–mass index
- CI = confidence interval
- logMAR = logarithm of the minimum angle of resolution
- OR = odds ratio
- QOL = quality of life
- SD = standard deviation
