Background. Osteoarthritis (OA) serves as one of the most prevalent types of joint disorders and is a leading cause of symptoms of stiffness, swelling, and arthralgia. Circular RNAs (circRNAs) have been reported to participate in various cellular processes by competing with microRNAs. Meanwhile, cyclinD1 (CCND1) is a key cell cycle regulatory protein and plays a crucial role in OA progression. Nevertheless, the function of circRHOT1 in the modulation of OA progression is still obscure. Here, we explored the effect of circRHOT1 on autophagy and extracellular matrix (ECM) in OA. Methods. The expression of circRHOT1 and autophagy markers was detected in OA samples. The effect of circRHOT1 on OA was analyzed in the OA rat model. The function of circRHOT1 in the regulation of OA was assessed by CCK-8, colony formation, flow cytometry analysis, quantitative real-time PCR, Western blot analysis, and luciferase reporter gene assay in chondrocytes. Results. We observed that autophagy markers, including LC3 and beclin1, were repressed in clinical OA samples. The expression of circRHOT1 and CCND1 was induced but the miR-142-5p expression was reduced in clinical OA samples. The miR-142-5p expression was negatively correlated with circRHOT1 and CCND1, and the circRHOT1 expression was positively associated with CCND1 in clinical OA samples. Meanwhile, the apoptosis was induced in OA rats but the depletion of circRHOT1 could block the phenotype in the rats. The articular cartilage degeneration was promoted in OA rats, while the knockdown of circRHOT1 repressed the degeneration. The serum levels of CTX-II and COMP were increased in OA rats, and the silencing of circRHOT1 downregulated levels of these proteins. In addition, the expression of collagen II and aggrecan was promoted by the depletion of circRHOT1 in the OA rats. Significantly, the expression of LC3 and beclin1 was suppressed in OA rats, in which the knockdown of circRHOT1 could reverse the effect. Moreover, the depletion of circRHOT1 repressed the cell viability and proliferation but induced apoptosis of chondrocytes. The expression levels of LC3, beclin1, collagen II, and aggrecan were induced by circRHOT1 knockdown. Mechanically, circRHOT1 was able to enhance the CCND1 expression by sponging miR-142-5p in chondrocytes. The overexpression of CCND1 or the inhibition of miR-142-5p reversed circRHOT1 depletion-mediated chondrocyte phenotypes. Conclusions. Circular RNA RHOT1 enhances the CCND1 expression by sponging miR-142-5p to inhibit chondrocyte autophagy and promote chondrocyte proliferation in osteoarthritis. Our findings provided a promising therapeutic target for OA.
1. Background

Osteoarthritis (OA) is one of the most frequently occurring types of bone and joint diseases, often causing symptoms of stiffness, swelling, and arthralgia, which compromises the abnormal joint functions and even causes disability of joints [1]. OA is characterized by impaired integrity of articular cartilage, inflammation of synovia, and narrowed joint space [1]. Currently, no therapeutic method is effective for OA, and joint replacement surgery is the only option for OA patients to alleviate the symptoms [2]. Hence, it is urgent to decipher more detailed mechanisms of OA pathogenesis. Chondrocytes and the extracellular matrix (ECM) are the only components of articular cartilage [1], of which the chondrocytes are the only cell form and are capable of releasing multiple kinds of inflammatory cytokines, and hence play a significant role in the progression of OA [3]. Besides, the homeostasis of ECM components, mainly the aggrecan and collagen II, could be disturbed by the abnormal levels of inflammatory cytokines released by chondrocytes [4]. Therefore, maintaining the survival and normal function of chondrocytes is critical for OA treatment.

Autophagy is a common cellular process that recycles the constituents of abnormal organelles such as lipids, proteins, and useless components to protect survival and normal functions of cells [5]. Nevertheless, the sustained autophagy could cause cell death [5]. Studies have revealed the participation of autophagy in maintaining the homeostasis of cartilage and skeletal morphogenesis during joint development [6–9]. It has been reported that depletion of Atg5, an autophagy regulator, led to exacerbated OA [10]. The autophagy repressor mTOR maintained chondrocyte autophagy and alleviated aging-induced OA [11].

Circular RNAs (circRNAs) are noncoding RNA with specific covalently closed circular RNA structures [12]. Accumulating evidence has pointed out the involvement of circRNAs during various diseases, via acting as the sponges of microRNAs (miRNAs) and subsequently modulating the expression of targeted mRNAs [12]. CircRHOT1 has been reported to be elevated in several cancers such as hepatocellular carcinoma, breast cancer, and pancreatic cancer and modulates cell proliferation, invasion, and apoptosis [13, 14]. Recently, numerous circRNAs have been found aberrantly expressed in OA tissues compared with counterparts. More importantly, circRNAs have been demonstrated to interplay with components in OA microenvironments, such as chondrocytes, synoviocytes, and macrophages, by regulation of their proliferation, apoptosis, autophagy, inflammation, or extracellular matrix reorganization [15], but the clinical significance of circRNAs remains unclear. Yet, the role of circRHOT1 during OA progression and cell autophagy has not been explored.

In this work, we explored the role of circRHOT1 in OA, determined its elevated level in patients with OA, and deciphered that the circRHOT1 modulated autophagy of chondrocytes via regulating the miR-142-5p/CCND1 regulatory axis.

2. Materials and Methods

2.1. Patient Samples. The OA cartilage samples were obtained from 30 patients who underwent knee replacement surgery, and the normal cartilage samples were collected from 30 patients who underwent arthroscopic knee surgery. OA was confirmed by clinical imaging diagnosis. All patients and relatives were informed of the use of knee cartilages in research before surgery and informed consents were obtained. The normal control cartilage samples were used in this study, which was from amputated knees of trauma patients. All patients and their relatives were informed of the research use of knee cartilages before surgery, and their consents were obtained. None of the trauma patients was previously diagnosed with OA. All cartilage samples were gathered in the medial compartment of the femur, and the normal control cartilage samples did not show cartilage damages under gross observation. This study protocol was reviewed and approved by Nanjing Lishui District Hospital of Traditional Chinese Medicine.

2.2. OA Rat Model. To establish the in vivo OA model, we purchased Sprague-Dawley (SD) rats (12-week old) from Charles River Laboratories (China) and conducted anterior cruciate ligament transection (ACLT) surgery to the left knees following William’s protocol [16]. The rats were housed in a condition of 25°C and 50% relative humidity with a 12 h light/dark cycle and a free access to standard chow and tap water. The rats in the control group (n = 6) were subjected to the arthroscopy without ACLT. The rats in the treatment group (n = 6) or mock group (n = 6) received intra-articular injection of circRHOT1 or negative control circRNA (10 μg/100 g) twice a week. Six weeks after operation, the severity of cartilage damage was determined by Mankin score and OARSI score. The rats were then sacrificed, and the joints were collected for following experiments. To evaluated the onset of OA, the serum levels of C-terminal crosslinking teleopeptide of type II collagen (CTX-II) and cartilage oligomeric matrix protein (COMP) were measured by enzyme-linked immunosorbent assay (ELISA) assay (Nordic Bioscience A/S, Herlev, Denmark) in line with the manufacturer’s instruction. Animal care and method procedure were authorized by the Animal Ethics Committee of Nanjing Lishui District Hospital of Traditional Chinese Medicine (Approval No. 2020-0622-37). The procedures were conformed to the Guide for the Care and Use of Laboratory Animal published by the US National Institutes of Health (NIH publication, 8th edition, 2011).

2.3. Cell Cultures and Transfection. Chondrocytes were extracted following a reported article [17]. The cartilage tissues were isolated from rats, digested by collagenase I, and cultured in DMEM medium (HyClone, Utah, USA) supplemented with 10% fetal bovine serum (FBS, HyClone, Utah, USA). In brief, primary chondrocytes were isolated from the bilateral hip joints of male 4-week-old rats which were purchased from Sino-British Sippr/BK Lab Animal, Ltd. (Shanghai, China). Cartilage of rat hip joint was cut into
Figure 1: Continued.
1 mm³ pieces in a sterile manner. Then, the cartilage pieces were digested with 0.25% trypsin for 1 h and incubated with 0.2% collagenase II in DMEM-F12 at 37°C and 5% CO₂ for 6 h. After that, chondrocyte suspensions were centrifuged at 1200 rpm for 5 min and cultured at 37°C and 5% CO₂ in DMEM-F12 complete culture medium which supplemented with 10% FBS and 1% penicillin and streptomycin at a density of 1 × 10⁵ cells/ml. The miR-142-5p mimics and inhibitors, siRNA targeting circRHOT1 or CCND1, and the negative controls were synthesized by GenePharma (Shanghai, China). Cell transfection was performed by using Lipofectamine 2000 (Invitrogen, Massachusetts, USA) according to the manufacturer’s description.

2.4. Cell Viability and Proliferation. The viability of chondrocytes was detected by using the Cell Counting Kit-8 (CCK8, Beyotime, Shanghai, China). In brief, cells were seeded in 96-well plates, treated with indicated reagents, and were incubated for 24, 48, 72, and 96 hours. The CCK8 reagent (10 μL) was added to each well to hatch for another 2 hours. The absorbance values at 450 nm were measured by a microplate detector (PerkinElmer, Germany).

The viability of chondrocytes was determined by qPCR in clinical OA samples (n = 30) and healthy cases (n = 30). The expression of CircRHOT1 was detected by qPCR in clinical OA samples (n = 30) and healthy cases (n = 30). The expression of CCND1 was determined by qPCR in clinical OA samples (n = 30) and healthy cases (n = 30). The expression of miR-142-5p was analyzed by qPCR in clinical OA samples (n = 30) and healthy cases (n = 30). (f)–(h) The correlation of circRHOT1, miR-142-5p, and CCND1 was analyzed in clinical OA samples (n = 30). Mean ± SD, **P < 0.01.

2.6. Flow Cytometry

2.6.1. Cell Cycle and Apoptosis Were Evaluated by Flow Cytometry. To assess cell cycle, chondrocytes were collected, fixed in 75% ethanol, and hatched with PI reagent (Beyotime, Shanghai, China) in dark for 30 minutes. The samples were then detected by a flow cytometer (BD Biosciences, USA). For cell apoptosis evaluation, chondrocytes were collected, washed, and then stained with Annexin V-FITC (5 μL) and PI (5 μL) in dark for 20 minutes. The portion of apoptotic cells was detected by the flow cytometer (BD Biosciences, New York, USA). The experiments were independently repeated at least three times.

2.7. RNA Extraction and Quantitative Real-Time PCR. The cartilage tissues and cells were homogenized with ice-cold TRIzol Reagent (Thermo, New York, USA) to obtain total RNAs. The RNAs were subjected to reverse-transcription with First Strand Synthesis Kit (Transgen, China), followed by quantification with Taq-Man Universal PCR Master Mix. The relative quantification of genes was normalized to U6 or GAPDH with a 2^ΔΔCt method, respectively. The primer sequences are as follows: circRHOT1 forward: 5'-ATCACCATCCAGCGGTGTG-3', reverse: 5'-TGCTGCTTTTGCTGTTCCTCC-3'; miR-142-5p: sense, 5'-GGCCGCAGATAAAGAAGC-3'; antisense, 5'-GGTGCGAGGGTGTCGAAGAT-3'; CCND1 forward: 5'-CCCTCGGTGTCTCATACTTCAA-3', reverse: 5'-GTGTCAATGAAATCGTGCG-3'; U6: sense, 5'-AACGGATTGTTGCTGTATTTTGGG-3'; antisense, 5'-TGCACACACTTGTTCTCCTGGGA-3'; GAPDH forward: 5'-AAAGGATGTGGTGATGGG-3', reverse: 5'-TCCTAGCTTGATGGG-3'.

2.8. Western Blotting. The expression of autophagy-related proteins, including LC3 and beclin1, was analyzed. The articular cartilages and chondrocytes were homogenized by using an ice-cold RIPA lysis buffer (Beyotime, China) to...
Figure 2: Continued.
obtain total proteins. After quantification by BCA kit (Beyotime, China), an equal amount of proteins was loaded and separated by SDS-PAGE and shifted to NC membranes. The membranes were blocked in 5% skim milk, probed by primary antibodies against LC3 (1:1000, Abcam, New York, USA), beclin1 (1:1000, Abcam, New York, USA), collagen II

Figure 2: CircRHOT1 represses autophagy and in the OA rat model. (a)–(e) The OA rat model was constructed by receiving ACLT, and the OA rats were treated with circRHOT1 shRNA. (d, e) The articular cartilage degeneration was presented by Mankin score and OARSI score. (f, g) The serum levels of CTX-II and COMP were measured by ELISA assay. (h) The expression of collagen II and aggrecan was detected by Western blot analysis. (i) The protein expression of LC3 and beclin1 was detected by Western blot analysis. Mean ± SD, **P < 0.01.
Figure 3: Continued.
apoptosis was assessed by FACS flow cytometer. (e) The cell apoptosis was assessed by FACS flow cytometer. Mean ± SD, **P < 0.01.

2.9. Luciferase Reporter Gene Assay. The wild type (WT) and mutated (MUT) sequences of circRHOT1 and CCND1 3′ UTR were cloned into pmirGLO plasmids (Promega, Wisconsin, USA), respectively. Chondrocytes were transfected with the WT or MUT plasmids along with the reference pRLTK vectors and incubated for 48 hours. Cells were then homogenized to detect the luciferase activity by using a luciferase viability detection kit (Promega, Wisconsin, USA) in accordance with manufacturer’s protocol.

2.10. Statistics. Data were shown as means ± S.D. of at least three independent experiments. The statistical analysis was conducted using GraphPad Prism 7.0 (USA). The differences between two or multiple groups were checked by Student’s t-test or one-way ANOVA analysis, respectively. The correlation between miR-142-5p, circRHOT1, and CCND1 was evaluated by the Pearson χ² test. The P < 0.05 was set as statistically significant.

3. Results

3.1. The Expression of circRHOT1, miR-142-5p, CCND1, and Autophagy Markers in OA Patients. To analyze the correlation of circRHOT1, miR-142-5p, CCND1, and autophagy with OA, we explored the expression of circRHOT1, miR-142-5p, CCND1, and autophagy markers in OA patients. We observed that autophagy markers, including LC3 and beclin1, were repressed in clinical OA samples (Figures 1(a) and 1(b), P < 0.01). Meanwhile, the expression of circRHOT1 and CCND1 was induced but the miR-142-5p expression was reduced in clinical OA samples (Figures 1(c)–1(e), P < 0.01). In addition, we found that the miR-142-5p expression was negatively correlated with circRHOT1 and CCND1, and the circRHOT1 expression was positively associated with CCND1 in clinical OA samples (Figures 1(f)–1(h)).

3.2. CircRHOT1 Represses Autophagy and Induces Injury in the OA Rat Model. Next, we evaluated the function of circRHOT1 in the OA rat model. The expression of circRHOT1 was induced in OA rats but was repressed by the depletion of circRHOT1 (Figure 2(a), P < 0.01). The apoptosis was induced in OA rats but the depletion of circRHOT1 could block the phenotype in the rats (Figures 2(b) and 2(c), P < 0.01). The articular cartilage degeneration was promoted in OA rats, as demonstrated by the increased Mankin score and OARSI score, while the knockdown of circRHOT1 repressed the degeneration (Figures 2(d) and 2(e), P < 0.01). The serum levels of CTX-II and COMP were increased in OA rats, and the silencing of circRHOT1 downregulated the levels (Figures 2(f) and 2(g), P < 0.01). In addition, the expression of collagen II and aggrecan was promoted by the depletion of circRHOT1 in the OA rats (Figure 2(h)). Importantly, the expression of LC3 and beclin1 was suppressed in OA rats, in which the knockdown of circRHOT1 could reverse the effect (Figure 2(i)).

3.3. CircRHOT1 Contributes to the Proliferation of Chondrocytes. Then, we assessed the function of circRHOT1 in the modulation of proliferation of chondrocytes. The depletion of circRHOT1 by shRNA was validated in chondrocytes (Figure 3(a), P < 0.01). The depletion of circRHOT1 repressed the cell viability of chondrocytes (Figure 3(b), P < 0.01). Consistently, the colony formation numbers of chondrocytes were reduced by circRHOT1 knockdown (Figure 3(c), P < 0.01). Meanwhile, the proportion of chondrocytes at G0/G1 phase was enhanced, and S
phase chondrocytes were reduced by circRHOT1 depletion (Figure 3(d), \( P < 0.01 \)). The silencing of circRHOT1 induced apoptosis of chondrocytes (Figure 3(e), \( P < 0.01 \)).

3.4. CircRHOT1 Represses Autophagy and ECM in Chondrocytes. Next, we observed that the expression levels of LC3 and beclin1 were enhanced by the depletion of circRHOT1 in chondrocytes (Figures 4(a)–4(c)). Moreover, the knockdown of circRHOT1 promoted the expression levels of collagen II and aggrecan in chondrocytes (Figures 4(d)–4(f)).

3.5. CircRHOT1 Is Able to Enhance the CCND1 Expression by Sponging miR-142-5p in Chondrocytes. Then, we explored the mechanism of circRHOT1 in the regulation of chondrocytes. The potential interaction of miR-142-5p with circRHOT1 and CCND1 was predicted (Figure 5(a)). The effectiveness of miR-142-5p mimic was validated in chondrocytes (Figure 5(b), \( P < 0.01 \)). Meanwhile, the treatment of miR-142-5p mimic suppressed the luciferase activities of circRHOT1 and CCND1 3′UTR in chondrocytes (Figures 5(c) and 5(d), \( P < 0.01 \)). The depletion of circRHOT1 enhanced the expression of miR-142-5p in chondrocytes (Figure 5(e),...
The expression of CCND1 was downregulated by circRHOT1 knockdown, while the inhibitor of miR-142-5p could rescue the expression of CCND1 in chondrocytes (Figure 5(f), P < 0.01).

3.6. CircRHOT1 Contributes to the Proliferation of Chondrocytes by Targeting the miR-142-5p/CCND1 Axis. Then, we assessed the function of the circRHOT1/miR-142-5p/CCND1 axis in the modulation of proliferation of chondrocytes. We identified that the cell viability of chondrocytes was repressed by the depletion of circRHOT1, while the overexpression of CCND1 or the inhibition of miR-142-5p rescued the phenotype (Figure 6(a), P < 0.01). The colony formation numbers of chondrocytes were inhibited by circRHOT1 knockdown, while the CCND1 overexpression or miR-142-5p inhibitor could reverse the effect (Figures 6(b) and 6(c), P < 0.01). In addition, the depletion of circRHOT1 promoted the apoptosis of chondrocytes, in

which the CCND1 overexpression or miR-142-5p suppression blocked the effect (Figures 6(d) and 6(e), \( P < 0.01 \)).

4. Discussion

OA is one of the most prevalent types of joint disorders and is a leading cause of symptoms of stiffness, swelling, and arthralgia. CircRNAs play crucial functions in multiple physiological and pathological processes. Nevertheless, the effect of circRHOT1 on OA progression remains elusive. In this study, we identified the function of circRHOT1 in the modulation of autophagy and ECM in OA.

Several circular RNAs have been reported in the regulation of OA. It has been reported that circular RNA CSNK1G1 contributes to OA progression by regulating the miR-4428/FUT2 signaling [18]. Circular RNA CDR1as serves as a sponge of microRNA-641 to enhance OA progression [19]. Circular RNA circPDE4D relieves OA by targeting miR-103a-3p and enhancing FGF18 expression [20]. Meanwhile, it has been found that circRHOT1 enhances progression and represses ferroptosis of breast cancer by the mir-106a-5p/STAT3 axis [13]. CircRHOT1 promotes non-small-cell lung cancer pathogenesis by epigenetically inducing the C-MYC expression via KAT5 [21]. CircRHOT1 contributes to progression of hepatocellular carcinoma by regulating the NR2F6 expression [22]. In the present work, we found that the apoptosis was induced in OA rats but the depletion of circRHOT1 could block the phenotype in the rats. The articular cartilage degeneration was promoted in OA rats, while the knockdown of circRHOT1 repressed the degeneration. The serum levels of CTX-II and COMP were increased in OA rats, and the silencing of circRHOT1 downregulated the levels. In addition, the expression of collagen II and aggrecan was promoted by the depletion of circRHOT1 in the OA rats. Significantly, the expression of LC3 and beclin1 was suppressed in OA rats, in which the knockdown of circRHOT1 could reverse the effect. Moreover, the depletion of circRHOT1 repressed the cell viability and proliferation but induced apoptosis of chondrocytes. The expression levels of LC3, beclin1, collagen II, and aggrecan were induced by circRHOT1 knockdown. These findings provide new insight into the function of circRHOT1 in the modulation of OA. The clinical significance of circRHOT1 should be confirmed by more investigations.

Moreover, it has been reported that fibroblast-like synoviocyte-derived exosomal PCGEM1 contributes to IL-1β-induced cartilage matrix degradation and apoptosis in chondrocytes by targeting the miR-142-5p/RUNX2 axis [23]. BLACAT1 modulates bone marrow stromal stem cell differentiation in OA by targeting miR-142-5p [24]. MiR-142-5p attenuates OA progression by competing with
5. Conclusions
Circular RNA RHOT1 enhances the CCND1 expression by sponging miR-142-5p to inhibit chondrocyte autophagy and promotes chondrocyte proliferation in osteoarthritis. Our findings provided a promising therapeutic target for OA.
