Abstract:
Identification of gene clusters in *Streptomyces* holds promise for the discovery of regulatory pathways linked to bioactive metabolites. We isolated a broad-spectrum antibacterial potential *Streptomyces* sp BDUSMP 02 from mangrove sediment. We further found a distinct of phylogeny pattern for NRPS A-domain in the *Streptomyces* sp BDUSMP 02. The result suggests that *Streptomyces* sp BDUSMP 02 has the potential to produce a new type of antibacterial compounds belonging to NRPS type.

Keywords: Mangrove, *Streptomyces*, NRPS, adenylate domain, Phylogeny

Background:
In the last five decades, natural compounds produced by actinobacteria have been enormously utilized to develop most of the common antibiotics commercialized by pharmaceutical industries [1]. Given this, isolation of actinomycetes from unexplored marine environment has been attracted particular attention due to their structural diversity and distinct bioactivities of secondary metabolites produced by them [2]. In evidence, *Salinispora* comes under the genus *Actinomycete* was first isolated from ocean sediments [3]. Mangrove forests are located in the tidal zones in tropical and subtropical regions [4]. Bisset et al. (2007) reported that mangrove sediments are known to contain high organic content, which favour the rapid development of species diversity corresponding to environmental variation [5]. The exploitation of mangrove actinomycetes for bioactive compounds has been increased dramatically [6-8]. *Streptomyces* sp isolated from mangrove ecosystem have been able to grow in freshwater, brackish water and seawater which suggest that they are adapted to various environmental conditions due to the water current [7]. Besides, it could be a starting point to study the evolution of gene clusters responsible for the biosynthesis of novel antibiotic because of their adaptation to extraordinarily salty and marshy condition [7]. It is evident that gene clusters in *Streptomyces* likely to encode natural product biosynthetic pathways in sequenced microbial genomes [9]. The biosynthetic potential of different strains isolated
from various sources can be approximated by the detection of the genes involved in the synthesis of secondary metabolites such as those for a polyketide synthase (PKS) and non-ribosomal peptide synthetase (NRPS). Non-ribosomal peptide synthetases (NRPSs) are megaenzymes usually with a modular structure, which catalyze the non-ribosomal assembly of peptides from proteinogenic and non-proteinogenic amino acids [10, 11]. Schwarzer and Marahiel (2001) reported that an NRPS module usually contains an adenylation domain (A-domain), a peptidyl carrier protein domain (PCP-domain), and a condensation domain (C-domain) [12]. There are eight core motifs have been postulated in A domain of NRPS including A1-A8 (A1, LKAGxAYVPID; A2, LAYxxTYSGTTGxPKG; A3, FDxS; A4, NyGPFTE; A5, GELxxGxGSLRGYW; A6, YKTGDQ; A7, GRxDxQxKIRGx; A8, NGKIDR) and they are highly conserved [13]. Komaki and Harayama (2006) reported that DNA sequence based on these genes could be used to predict the chemical nature of compounds [14]. The biological functions of NRPS via synthesized compounds associated with the chemical nature of peptide, which is correlated with the phylogenic insight of NRPS in the potential actinomycete would provide new opportunities for drug discovery.

Materials and Methods:
Isolation and identification of Actinomycetes:
Soil samples were collected from Mangrove sediment of Pitchavaram (Latitude of 11.4’ N-Longitude of 79.8’ E), Tamil Nadu, India, in sterile airlock polythene bags and transported to the laboratory according to a previously described method [6]. One gram of air-dried each spot soil samples was added to a 9 ml of sterile water and subjected to selective pretreatment of dry heat at 56°C for 10 min to effectively increase the number of mycelium-forming actinomycetes relative to the non-actinomycetal heterotrophic microbial flora. After that, the samples were vigorously shaken and further diluted up to 10^-6 in sterile water. 100μl of each diluted sample was inoculated by spreading with a sterile glass rod onto humic acid-vitamin B agar (HV) medium (Hayakawa & Ohara,1987) supplemented with antibiotics of cycloheximide (40 μg/ml), nystatin (30 μg/ml) and nalidixic acid (10 μg/ml) after autoclave to inhibit the fungal and nonfilamentous bacterial growth. The inoculated plates were incubated at 30°C for ten days or until appearance of colonies with a tough leathery texture, dry or folded appearance, and branching filaments with or without aerial mycelia.

Antibacterial activity:
Lyophilized cultures of Escherichia coli (MTCC 1687); Vibrio cholerae (MTCC 3906); Proteus mirabilis (MTCC 425); Klebsiella pneumoniae (MTCC3384); Staphylococcus aureus (MTCC 3160); Salmonella typhi (MTCC3231) was obtained from Microbial Type Culture Collection, IMTECH, India. All test strains were cultured at 37°C in Luria broth or on Luria agar. Antibacterial activity of cell-free supernatant was determined using the disc diffusion method. 100 μl of 8 hrs old culture broth of the test organisms were spread over on the surface of the Luria agar plate using a sterile cotton swab. After that, 60 μl of cell-free supernatant was added into sterile standard discs (HiMedia, India) and incubated for 18 to 24 hrs at 37°C. After that the clear incubation zone of inhibition (ZOI) was measured to evaluate the antimicrobial activity of actinomycetes isolate. Dimethyl sulphoxide (DMSO) was used as control.

NRPSs amplification, cloning, and sequencing
The NRPSs gene was amplified from genomic DNA of Streptomyces sp BDUSMP 02 using the previously described degenerate primers ADEdom 5' - CCA ACS GGC NNN CCS AAG GGC GT 3' and ADEdom 3' - ACC CTC SGT SGG SCC GTA 3' [15]. A 450- bp fragment encoding the adenylation domain of NRPS was amplified. The PCR was performed in a total volume of 50 μl containing one μM of each primer, 1μl of extracted DNA, 23 μl of sterile distilled H2O, and 10% (v/v) of DMSO to the final volume in PCR premix (Emerald, Takara, Japan). Amplifications were performed in a thermal cycler (Eppendorf, Germany). Polymerase chain reaction conditions were as follows: 5 min at 95°C followed by 40 cycles of 1 min at 94°C, 1 min at 60°C and 1.5 min at 72°C followed by a 10-min final extension step at 72°C. The purified PCR product was ligated pGEM® -T Vector according to the manufacturer’s instructions. Plasmid DNA from the transformants was isolated using the HiYield TM Plasmid Mini Kit (RBC, Korea). To confirm the cloned product, PCR was performed again using the primer pairs of T7 Promoter 5' TAA TAC GAC TCA CTA TAG GG 3' and SP6 Promoter 5' GAT TTA GGT GAC ACT ATA G 3'. The PCR was performed in a total volume of 50 μl containing one μM of each primer, 2 μl of extracted plasmid DNA, 23 μl of sterile distilled H2O, and 10% (v/v) of DMSO to the final volume in PCR premix (Emerald, Takara, Japan). Amplifications were performed in a thermal cycler (Eppendorf, Germany). Polymerase chain reaction conditions were as follows: 5 min at 95°C followed by 35 cycles of 1 min at 94°C, 1 min at 54°C and 1.5 min at 72°C followed by a 10-min final extension step at 72°C. The DNA sequencing was performed on an ABI 310 automatic DNA sequencer (Applied Biosystems) using the SP6 and T7 promoters primers.

Phylogenetic analysis of NRPS Adenylate domain
BLAST network services at the NCBI were used to analyze the resulting NRPSs gene sequence [16]. Multiple alignments were performed using CLUSTAL_X version 1.8 [17]. The phylogenetic tree was inferred Neighbor-joining method using MEGA 6.0 software package [18]. The unrooted phylogenetic tree topology was evaluated by using the bootstrap resamplings method with 1000 replicates [19].

Results and Discussion:
Isolation and characterization of Mangrove Actinomycete:

Antibacterial activity:
The isolate displayed significant antibacterial activities against test strains. The zone of inhibition was 15 mm, 14 mm, 18 mm, 18 mm, 12 mm and 10 mm for *Escherichia coli* (MTCC 1687), *Vibrio cholerae* (MTCC 3906), *Klebsiella pneumoniae* (MTCC3384), *Proteus mirabilis* (MTCC 425), *Salmonella typhi* (MTCC3231) and *Staphylococcus aureus* (MTCC 3160), respectively. In marine environments, it is noteworthy that mangrove sediments are known to have novel actinomycetes [6]. It has been documented that new bioactive compounds have been obtained from mangrove actinomycetes [20]. In agreement with those previous reports, the results presented in this study denoted that bioactive secondary metabolite production by the mangrove sediment actinomycete and its gene clusters responsible for the biosynthesis could be at a later stage taken into the molecular biology of natural product research.

NRPSs gene adenylation domain (A-domain):
*Streptomyces* sp. BDUSMP 02 non-ribosomal peptide synthetase gene, partial cds, has been deposited in GenBank database under Accession No. KJ598809.1. The resulting amino acid sequences corresponding to their nucleotide sequences of amplified NRPS A-domain showed conserved motif, as shown in Figure 1. There are three core motifs in the amplified 450 bp fragments of A-domain identified including A2, TGxPKGV, A3, FD and A4, NxYGPE.
NRPS A-domain was best matched with the previously reported *Streptomyces*. The resulting amino acid sequences shared low similarities with those available in databanks. Liu et al. (2019) reported that *Streptomyces* isolated from mangrove sediment harbouring NRPS genes which involved in the synthesis of the antibacterial compound. Secondary metabolite production in *Streptomyces* is growth dependent and involves the expression of physically clustered regulatory and biosynthetic genes by a tightly regulated mechanism [21]. Similarly, in the present study, biosynthetic NRPS gene sequences provided valuable genomic-based information in parallel with the antimicrobial activity of isolate. Our results thus proved the presence of NRPS genes in support of the bioassay-guided analysis for antibacterial activity.

**Phylogenetic analysis of NRPSs A-domain:**

*Figure 2* presents the phylogenetic tree of *Streptomyces* sp BDUSMP 02 based on NRPS A-domain amino acid sequence. The NRPS A-domain amino acid sequence of the isolate *Streptomyces* sp BDUSMP 02 showed a less identity to the sequences from various *Streptomyces* sp. A good agreement between bioassay-guided identification antibacterial properties this isolate had functional NRPS genes in their putative gene cluster responsible for the synthesis of antibacterial compounds. Interestingly the strain NRPS A-domain shared similarity with *Streptomyces avermilities*. It is therefore desirable to isolate the secondary metabolite with antibacterial properties to relate with its functional genes.

**Conclusion:**

We describe a *Streptomyces* sp. from mangrove environment as a promising source of novel antibacterial compounds. There is increasing interest in the characterization of gene clusters, which mainly contain NRPS, PKS and NRPS/PKS in addition to culture-dependent experimentation for distinct bioactivities. We found NRPS adenylate domain from the potential isolate, which can be further explored for the drug discovery using a genome mining approach.
