(Dated: July 11, 2021)

We compute the density dependence of the quark condensate and how it changes under the influence of isospin-asymmetric nuclear matter. This is achieved by the calculation of the relevant Feynman diagrams using in-medium chiral perturbation theory. We find that the absolute value of the quark condensate decreases in nuclear matter by around 35% at normal nuclear density, in agreement with previous model-independent calculations. We also present a quantitative estimation of the difference of up- and down quark in-medium condensates.

I. INTRODUCTION

The dynamical breaking of chiral symmetry (DBχS) is an intriguing phenomenon in the low-energy spectrum of quantum chromodynamics (QCD). One of the order parameters of this symmetry breaking process is the quark condensate ⟨¯qq⟩. In the symmetric phase, the value of the quark condensate is zero, and after the symmetry breaking phase transition, it acquires a finite value. It is expected that in extreme environments of the QCD phase transition, the quark condensate is zero, and after the symmetry restoration, it remains an open question up to which densities the chiral symmetry will be at least partially restored.

One way to confirm DBχS is therefore to investigate the partial restoration of the chiral symmetry in nuclear matter. Recent experimental results [1,2], as well as theoretical calculations based on these results [3,4], have revealed that the quark condensate should decrease by about 30% at the saturation density. In fact, this decrease of the quark condensate had been predicted by a model-independent low-density relation [5], which determines whether the quark condensate increases or decreases in nuclear matter. As the σπN term extracted from the πN scattering data has been found to have a positive sign [7], the quark condensate should decrease in nuclear matter—at least in the low-density region. However, it remains an open question up to which densities the low-density formalism can be applied.

This work is an extension of a previous work [8], where the quark condensate in symmetric nuclear matter was calculated based on the chiral Ward identity for the in-medium quark condensate proposed in Ref. [5]. The main distinction of the present work is, that we consider the more general case of isospin-asymmetric nuclear matter, where the densities of protons and neutrons can be varied independently. Previously, the so-called large mN limit, where expressions are expanded in powers of inverse nucleon masses, has been employed. This enables an analytical calculation of the integrals encountered, but in some cases the large mN limit leads to deviations compared to the full expression. In the present work we also found that more diagrams are necessary to fully describe the quark condensate. This includes topologically similar diagrams with different interaction vertices, as well as topologically distinct diagrams. These diagrams become especially important in isospin-asymmetric nuclear matter. In addition, we estimate the difference of the condensates for the up and down quarks in isospin-asymmetric nuclear matter in the linear density approximation.

There have been several other works that investigated the in-medium corrections to the density dependence of the quark condensate. Reference [6] investigated the in-medium quark condensate in pure neutron matter. In Ref. [7], the authors used in-medium chiral perturbation theory in order to calculate the density dependence of the quark condensate in isospin-symmetric nuclear matter. In particular, they included one- and two-pion exchanges, as well as Δ contributions and their results are in good agreement with this work. Furthermore, Ref. [8] investigated the temperature dependence of both ⟨¯uu + dd⟩ and ⟨¯uu − dd⟩ at zero density, as well as chiral susceptibilities, using explicit isospin breaking through mu ≠ m d and electromagnetic interactions in order to study chiral symmetry restoration. Let us note that the quark condensate plays an integral role in other contexts, too. For instance, there have been investigations on the response to a magnetic field [11,12], or a mechanism to generate neutrino masses [13]. Reference [14] pointed out that the wave function renormalization of the Nambu–Goldstone boson is a significant in-medium effect when chiral symmetry is partially restored. Finally, we note that by using the formalism described in this work, it is also possible to calculate in-medium hadron properties, e.g., in-medium pion properties [15]. However, in the present scope, we will exclusively focus on the in-medium quark condensate.

The structure of this paper is as follows. In Sec. II A we explicitly show how to calculate the in-medium quark condensate ⟨¯uu + dd⟩* from the SU(2) chiral Ward identity. In Secs. II B and II C, we introduce in-medium chiral perturbation theory and present the Lagrangian. In Sec. II D we list the Feynman diagrams that are used to calculate the quark condensate, and also their respective

* huebsch@th.phys.titech.ac.jp
integral representation. In Sec. III we show our numerical results for the in-medium quark condensate. In Sec. IV we show a quantitative estimation of \( \langle i\bar{u}u-\bar{d}d \rangle \), for which we use an SU(3) chiral Lagrangian. Section V is devoted to the summary and conclusion.

II. METHODS

We use in-medium chiral perturbation theory with an SU(2) chiral Lagrangian up to second order in the chiral counting. The goal is to calculate the pseudoscalar two-point correlation function, which leads us to the in-medium quark condensate as shown in Sec. IIIA. We next describe in-medium chiral perturbation theory in Sec. IIIB and subsequently discuss our Lagrangian in Sec. IIIC. In Sec. IID we derive the relation between the in-medium quark condensate and the pseudoscalar two-point correlation functions.

A. In-Medium Ward Identity

In this section, we show how to calculate the nuclear density dependence of the in-medium quark condensate. To do this, we follow Ref. [8] and use the chiral Ward identity. We start with the divergence of the following time-ordered product:

\[
\partial^\mu [T A^a_\mu(x) P^b(0)] = T[\partial^\mu A^a_\mu(x) P^b(0)] + \delta(x^0)[A^a_0(x), P^b(0)],
\]

where the axial vector current \( A^a_\mu(x) \) is the Noether current of the SU(2) chiral transformation and the pseudoscalar fields \( P^a(x) \) are defined in terms of the quark fields as \( P^a(x) = \bar{q}(x)i\gamma^5\tau^a q(x) \) with the Pauli matrices \( \tau^a \) for the isospin space. We assume isospin symmetry for the up and down quark masses. We can use the partially-conserved axial current (PCAC) relation \( \partial^\mu A^a_\mu(x) = \bar{m}P^a(x) \) with \( m \) the quark mass, and evaluate the whole equation between the in-medium vacuum \( |\Omega\rangle \), which is the ground state of the nuclear matter:

\[
\partial^\mu \Pi^a_{\mu\nu}(x,0) = m\Pi^a_{\mu\nu}(x,0) + \delta(x^0)\langle \Omega | [A^a_0(x), P^b(0)] |\Omega\rangle.
\]  

Here we abbreviated

\[
\Pi^a_{\mu\nu}(x,0) = \langle \Omega | T A^a_\mu(x) P^b(0) |\Omega\rangle,
\]

\[
\Pi^a_{\mu\nu}(x,0) = \langle \Omega | T P^a(x) P^b(0) |\Omega\rangle.
\]

We perform a Fourier transformation to momentum space,

\[
-iq^\mu \Pi^a_{\mu\nu}(q) = m\Pi^a_{\mu\nu}(q) = \int \text{d}^3x e^{-iq \cdot x} \langle \Omega | [A^a_0(x), P^b(0)] |\Omega\rangle,
\]

and take the soft limit \( q^\mu \to 0 \). This allows us to integrate over the last term, which gives the corresponding conserved Noether charge according to \( Q^a_5 = \int \text{d}^3x A^a_5(x) \):

\[
-i \lim_{q \to 0} q^\mu \Pi^a_{\mu\nu}(q) = m\Pi^a_{\mu\nu}(0) + \langle \Omega | [Q^a_5, P^b(0)] |\Omega\rangle.
\]

In order to continue, we employ the SU(2) chiral transformation behavior of the pseudoscalar current, \( [Q^a_5, P^b(0)] = -i\delta^{ab}\bar{q}q(0) \), to write the equation

\[
m\Pi^a_{\mu\nu}(0) + i \lim_{q \to 0} q^\mu \Pi^a_{\mu\nu}(q) = i\delta^{ab}\bar{q}q(0),
\]

where we have defined \( \Omega|\bar{q}q\rangle = \langle \bar{q}q |\rangle \equiv \langle \bar{u}u + \bar{d}d \rangle \) in Eq. (7). In the soft limit, the second term on the left hand side vanishes, since we do not have any zero modes present. Conversely, in the chiral limit, the first term would vanish, because \( m = 0 \), but the second term would survive owing to massless pion modes. In summary, by calculating the pseudoscalar two-point correlation function, Eq. (4), in chiral perturbation theory, we can infer the density dependence of the in-medium quark condensate. In summary, we use two QCD relations, PCAC and the Ward identity, in order to relate the quark condensate to pseudoscalar correlation functions, and then use chiral perturbation theory to compute those correlation functions.

We note that it is also possible to investigate the quark condensate via the Hellmann–Feynman theorem by taking derivatives of the nucleon energy density with respect to the quark mass, see e.g. Ref. [12] and references therein.

B. In-Medium Chiral Perturbation Theory

Chiral perturbation theory is an effective field theory, therefore its most fundamental quantity is the Lagrangian, which exhibits the symmetries of QCD. We follow the in-medium formalism initiated by Oller [9], and developed by Ref. [10]. Using the Lagrangian, we can construct the partition function \( Z \), which contains the information of all possible interactions. This generating functional is defined as the transition amplitude between two asymptotic in- and out-states, and can be written as the exponential of the functional of all connected Green functions \( W \):

\[
Z[J] = e^{iW[J]} = \langle \Omega_{\text{out}} | \Omega_{\text{in}} \rangle.
\]

We assume that these asymptotic states are described by Fermi seas of non-interacting protons and neutrons at times \( t \to \pm \infty \). They can be written as \( N \) excitations of the vacuum,

\[
|\Omega\rangle = \prod_i a^\dagger(p_i)|0\rangle,
\]
where we include all momenta up to the Fermi momentum, which depends on the nucleon density as

\[ k_F^{p,n} = (3\pi^2 \rho_{p,n})^{1/3} \].

Furthermore, \( a^\dagger(p) \) is a nucleon creation operator with momentum \( p \) and \( |0\rangle \) is the zero-particle vacuum state. Correlations between nucleons can be implemented by an interaction Lagrangian.

In the path integral formalism, the generating functional \( Z[J] \) can be expressed using the Lagrangian of the system,

\[ Z[J] = \int D\mathcal{U} D\mathcal{N} D\mathcal{N}^\dagger \langle \Omega_{\text{out}} | \mathcal{N}_{i=+\infty} \rangle e^{i \int d^4x (L_{\chi} + L_{N} + L_{\chi N}) \langle \mathcal{N}_{i=-\infty} | \Omega_{\text{in}} \rangle}, \tag{11} \]

where the full Lagrangian contains a pion term, a nucleon term and a pion–nucleon interaction term. The nucleon–nucleon contact interactions can be also included to describe nucleon–nucleon correlations, which can be important in \( O(p^2) \).

The nucleon field appears bilinear in the Lagrangian, which means it can be integrated out \( [9] \). This results in an expansion of Fermi sea insertions,

\[ Z[J] = \int D\mathcal{U} \exp \bigg\{ i \int d^4x \left[ \mathcal{L}_{\pi} - \int \tilde{d}p \mathcal{F}\tau \{ i\Gamma(x,y)(\not{p} + m_N)n(p) \} 
- \frac{i}{2} \int \tilde{d}p \tilde{d}q \mathcal{F}\tau \{ i\Gamma(x,x')(\not{q} + m_N)n(q)i\Gamma(y,y)(\not{p} + m_N)n(p) \} + \ldots \bigg\} \bigg\}, \tag{12} \]

where \( \tilde{d}p = d^3p (2\pi)^{-3}(2E(p))^{-1} \) denotes a Lorentz invariant integration measure, \( E(p) = (p^2 + m_N^2)^{1/2} \) is the nucleon energy for momentum \( p \). \( \mathcal{F}\tau \) represents a Fourier transformation of spatial variables (except for \( x \)) and \( \Gamma(x,y) \) is a non-local vertex defined via in-vacuum quantities,

\[ i\Gamma = A[\mathds{1}_4 - G_0 A]^{-1}. \tag{13} \]

Here, the interaction operator \( A \) and the free nucleon propagator \( G_0 \) are given by in-vacuum chiral perturbation theory. The matrix \( n(p) \) implements the different Fermi momenta of protons and neutrons,

\[ n(p) = 
\begin{pmatrix}
\Theta(k_F^p - |p|) & 0 \\
0 & \Theta(k_F^n - |p|)
\end{pmatrix} \],
\tag{14} \]

and restricts the momentum integration up to these Fermi momenta using Heaviside step functions. We will abbreviate these step functions as follows: \( \Theta^{p,n}_p \equiv \Theta(k_F^{p,n} - |p|) \). Finally, the non-local vertex \( \Gamma(x,y) \) in Eq. \( \tag{13} \) can be expanded in terms of the interaction operator \( A \) and the in-vacuum nucleon propagator \( G_0 \) like

\[ i\Gamma = A + AG_0 A + AG_0 AG_0 A + \ldots, \tag{15} \]

and the pion–nucleon interaction operator \( A \) will be discussed in the next section.

C. The Chiral Lagrangian

We employ a chiral Lagrangian up to second order in the chiral counting. There are two contributions to this

Lagrangian. We have the pion Lagrangian,

\[ \mathcal{L}_\pi^{(2)} = \frac{f_\pi^2}{4} \text{Tr} \left\{ D_\mu U \dagger D^\mu U + \chi \lambda U + \chi U \lambda \right\}, \tag{16} \]

which describes pion-pion interactions, as well as interactions of pions with external currents. The chiral field \( U \) is given in terms of the pion fields \( \pi = \pi^a \tau^a \):

\[ U = \exp \left( i \pi (\not{\pi}/2\sqrt{\pi^2}) \right) \quad (\pi^2 = \pi^a \pi^a). \tag{17} \]

Note that the function \( y(\pi^2) \) fulfills:

\[ y - \sin(y) = \frac{4}{3} \left( \frac{\pi^2}{f^2} \right)^{3/2}. \tag{18} \]

This parameterization of the chiral field enables a simple treatment of perturbative calculations \( [19,21] \): the partition function, Eq. \( \tag{12} \), is defined in terms of the chiral field \( U \), so when considering loop corrections to the pion field, one should be careful about chiral invariance of the integral measure. Furthermore, the Adler zero condition \( [22] \) is immediately fulfilled in this parametrization.

The covariant derivative \( D_\mu \) acts on the chiral field as

\[ D_\mu U = \partial_\mu U - i r_\mu U + iU \ell_\mu, \tag{19} \]

where \( r_\mu = (v_\mu + a_\mu)/2 \) and \( \ell_\mu = (v_\mu - a_\mu)/2 \). In these expressions, \( v_\mu = v_\mu^a \tau^a / 2 \) and \( a_\mu = a_\mu^a \tau^a / 2 \) are the external vector- and axial-vector fields \( (a = 1, 2, 3) \).

The field \( \chi \) contains the external scalar \( (s = s^a \tau^a, \quad a = 0, 1, 2, 3) \) and pseudoscalar \( (p = p^a \tau^a, \quad a = 0, 1, 2, 3) \) currents,

\[ \chi = 2B_0 (s + ip), \tag{20} \]
and $B_0$ is a low-energy constant (LEC). The quark mass is introduced through the external scalar field by setting $s = m\tau^0$ with the quark mass $m$.

The $\pi N$ interaction Lagrangian is given by

$$L_{\pi N} = -\bar{N}AN, \quad A = \sum_{i=1} A^{(i)},$$

where $A^{(i)}$ is of chiral order $O(p^i)$. The terms which are relevant to the present calculation read:

$$A^{(1)} = -i\gamma^\mu \Gamma^\mu - igA\gamma^5 \Delta_G,$$

$$A^{(2)} = -c_1 \text{Tr} \{ \chi^+ \} + \ldots$$

Here, we need the definitions of the vector and axial-vector currents:

$$\Gamma^\mu = \frac{1}{2} [u^\dagger, \partial^\mu u]$$

$$\Delta_G = \frac{1}{2} u^\dagger \left[ \partial^\mu - i(v^\mu + a^\mu) \right] u - \frac{1}{2} \partial^\mu \left( v^\mu - a^\mu \right) u^\dagger,$$

where $u^2 = U$. The scalar and pseudoscalar sources are contained in $\chi^+$:

$$\chi^+ = u\chi^1 u + u^\dagger \chi u^\dagger.$$  

The full definition of $A^{(1)}$ and $A^{(2)}$ are given in Appendix [A].

**D. In-Medium Quark Condensate**

In this section, we will calculate the in-medium quark condensate through $\Pi^{ab}(0)$ using Eq. (26). For this purpose we will present the Feynman diagrams for the calculation of $\Pi^{ab}(0)$. These diagrams all start and end with a wavy line, representing an external pseudoscalar and Dirac indices.

The leading contribution to the in-medium quark condensate in the density expansion reads:

$$\Pi_1 = \sum_{i=1}^{2} \gamma^{(2)} \gamma^{(2)} + 2 \gamma^{(2)} \gamma^{(2)}$$

Thick lines are in-medium nucleon propagators, dashed lines are pion propagators, wavy lines are pseudoscalar currents, and the number inside a vertex represents whether this interaction comes from $A^{(1)}$ or $A^{(2)}$. If no nucleon participates in an interaction, then only $L^{(2)}$ yields a contribution. We have listed all necessary interaction Lagrangians in Sec. [III]. We count the last diagram in Eq. (26) twice in order to account for the fact that the in-medium nucleon loop can be attached to either vertex. We now show how to apply the Feynman rules which are needed to calculate these diagrams using the second diagram in Eq. (26) as an example:

$$\lim_{q^\alpha \to 0} (-1)^L \frac{(-1)^n}{n} \frac{(-1)^2}{2} \int \frac{d^3p}{(2\pi)^3} \frac{1}{2p_0} \times \text{Tr} \left\{ -iA^{(2)}_{\pi p} (\not{p} + m_N)n(p) \right\} \frac{i\delta^{ac}}{q^2 - m^2} \left[ i\mathcal{L}^{(2)}_{\pi p} \right].$$

Here, we have one fermionic loop, $L = 1$, one Fermi-sea propagator, $n = 1$, and two external currents in the correlation function, thus we get a factor of $(-1)^2$. Due to energy-momentum conservation, $p_0 = (p^2 + m_N^2)^{1/2}$. The relevant terms in the Lagrangian are:

$$A^{(2)}_{\pi p} = -\frac{8c_1B_0}{f} p^i p^j, \quad \mathcal{L}^{(2)}_{\pi p} = 2fB_0 p^i p^j,$$

which implies that the trace both for isospin and Dirac indices simplifies to:

$$\text{Tr} \left\{ (\not{p} + m_N)n(p) \right\} = 4m_N^2(\Theta_p + \Theta_p^n),$$

and we obtain:

$$-i\delta^{ab} \frac{16c_1B_0^2m_N}{\pi^2 m_N^{1/2}} \int dp^2 \frac{p^2}{p_0^2} (\Theta_p + \Theta_p^n).$$

As written in Eq. (7), we multiply the pseudoscalar correlation function with the quark mass and also divide by the vacuum condensate, which is given at tree level by $\langle \bar{q}q \rangle_0 = -2f^2B_0 + \ldots$ in order to obtain the contribution to the in-medium quark condensate. The pion mass and the quark mass are related in leading order chiral perturbation theory via $m_N^2 = 2mB_0 + \ldots$, which fixes the value for $B_0$. After multiplying this diagram by 2 and adding the other diagram in Eq. (26), the result is:

$$\frac{m_N^{1/2}}{\langle \bar{q}q \rangle_0} = \frac{i\delta^{ab} 4c_1m_N}{\pi^2 f^2} \int dp^2 \frac{p^2}{p_0^2} [\Theta_p + \Theta_p^n].$$

This integral can be evaluated analytically:

$$\int_0^{k_F} dp \frac{p^2}{\sqrt{p^2 + m_N^2}} = \frac{k_F}{2} \sqrt{k_F^2 + m_N^2} - \frac{m_N^2}{2} \arctanh \left( \frac{k_F}{\sqrt{k_F^2 + m_N^2}} \right),$$

so we can expand it in the large-$m_N$ limit as follows:

$$\frac{m_N}{\pi^2} \int dp^2 \frac{p^2}{p_0^2} [\Theta_p + \Theta_p^n] = \frac{1}{10m_N^5} \left[ \frac{3^2\pi^4}{(1 + r)^5} \right]^{1/3} + \mathcal{O} \left( \frac{1}{m_N} \right),$$

where $r = 5/3 + 5/3 \frac{m_N^{1/2}}{10m_N^5} \left[ \frac{3^2\pi^4}{(1 + r)^5} \right]^{1/3} + \mathcal{O} \left( \frac{1}{m_N} \right),$
where we abbreviate the neutron-to-proton ratio \( r = \rho_n / \rho_p \). Since the expression in Eq. (31) is invariant under the exchange of \( k_F^p \) and \( k_F^n \), it is consequently also invariant under the exchange of \( \rho_p \) and \( \rho_n \). This symmetry is also present in the other diagrams.

The next-to-leading contributions in the density expansion are given by \( \Pi_2, \Pi_3 \) and \( \Pi_4 \):

\[
\Pi_2 = 2 \quad \Pi_3 + 2 \quad \Pi_4 \quad (34)
\]

\[
\frac{m\Pi_{2,1}^{ab}(0)}{\langle \bar{q}q \rangle_0} = i\delta^{ab} \frac{g^2 m_N^2}{5(2\pi f)^2} \int dp \, dk \, d\cos \theta \, p k_0 \, p k_0 - p k - m_N^2 \left( \Theta^a_p \Theta^b_p + 4\Theta^a_p \Theta^b_n + 4\Theta^a_n \Theta^b_p + \Theta^a_n \Theta^b_n \right)
\]

\[
+ i\delta^{ab} \frac{g^2 m_N^2}{10(2\pi f)^4 m^2} \int dp \, dk \, d\cos \theta \, p k_0 \, p k_0 - p k - m_N^2 \left[ a_1 (\Theta^a_p \Theta^b_p + \Theta^a_n \Theta^b_n) + a_2 (\Theta^a_p \Theta^b_n + \Theta^a_n \Theta^b_p) \right]
\]

\[
\frac{m\Pi_{2,2}^{ab}(0)}{\langle \bar{q}q \rangle_0} = i\delta^{ab} \frac{g^2 m_N^2}{10(2\pi f)^4 m^2} \int dp \, dk \, d\cos \theta \, p k_0 \, p k_0 - p k - m_N^2 \left[ 2m^2_\pi - 6(p - k)^2 \right] \left( \Theta^a_p \Theta^b_p + \Theta^a_n \Theta^b_n \right) \]

which lead to the following terms:

\[
\frac{m\Pi_{3}^{ab}(0)}{\langle \bar{q}q \rangle_0} = \frac{g^2 m_N^2}{10(2\pi f)^4 m^2} \int dp \, dk \, d\cos \theta \, p k_0 \, p k_0 - p k - m_N^2 \left[ 2m^2_\pi - 6(p - k)^2 \right] \left( \Theta^a_p \Theta^b_p + \Theta^a_n \Theta^b_n \right) \]

which results in:

\[
\Pi_3 = \quad (35a)
\]

(35b)

Here we abbreviated:

\[
p_k = p_0 k_0 - p k, \quad (36a)
\]

\[
a_1 = 2(p - k)^2 + m^2_\pi, \quad (36b)
\]

\[
a_2 = -2(p - k)^2 + 4m^2_\pi, \quad (36c)
\]

and can simplify \((p - k)^2 = 2m^2_\pi - 2p_0 k_0 + 2p k \cos \theta\).

The next set of diagrams cancel each other in the soft limit, where the external pion momentum goes to zero:

\[
\Pi_3 = \quad (37)
\]

The last diagram we consider for the next-to-leading order in the density expansion is:

\[
\Pi_4 = \quad (38)
\]

which results in:

\[
\frac{m\Pi_{4}^{ab}(0)}{\langle \bar{q}q \rangle_0} = i\delta^{ab} \frac{g^2 m_N^2}{10(2\pi f)^4 m^2} \int dp \, dk \, d\cos \theta \, p k_0 \, p k_0 - p k - m_N^2 \left[ 2m^2_\pi - 6(p - k)^2 \right] \left( \Theta^a_p \Theta^b_p + \Theta^a_n \Theta^b_n \right) \]

According to Eq. (7), the pseudoscalar correlation function \( \Pi_{2}^{ab} \) is only proportional to \( \delta^{ab} \). Still, we also found contributions proportional to \( \delta^{ab}\delta^{3} \) and \( \delta^{ab}\delta^{5} \), but after adding all diagrams, the contributions proportional to \( \delta^{ab}\delta^{3} \) exactly cancel each other, in accordance with chiral symmetry. Otherwise, this would violate the chiral \( SU(2) \) symmetry because the third isospin component of the pseudoscalar current \( P^a \) would behave in a different way compared to the other two components: \( \Pi^{11} = \Pi^{22} \neq \Pi^{33} \).

III. RESULTS

In this section, we show our numerical results. In our calculations, we use the following numerical values for the low-energy constant \( c_1 = -0.59 \) GeV\(^{-1} \), the pion decay constant \( f_\pi = 92.4 \) MeV, and the axial coupling
for isospin-symmetric nuclear matter. In this work, we found several new diagrams which are necessary contributions to the in-medium quark condensate. In particular, the first diagram in Eq. (26) with $i = 1$, the second diagram in Eq. (37) with $i = 1$ as well as the third diagram in Eq. (37) with $i \neq j$. Furthermore, diagrams like the one in Eq. (38) were not considered at all in Ref. [8]. Comparing to Ref. [12] and related works, we include interactions from $A^{(2)}$, but omit $2\pi$-exchange and $\Delta$-excitation processes, as they contribute beyond $O(\rho^{5/3})$. In order to include such processes, Ref. [12] uses a nucleon-nucleon potential obtained from lattice QCD data.

Despite being a small contribution, the isospin-asymmetry of the surrounding nuclear matter plays a role in the in-medium quark condensate. As shown in Fig. 3 for normal nuclear density $\rho = \rho_0$, different values for the neutron-to-proton ratio have a small effect on the in-medium quark condensate. In particular, when plotted logarithmically, one can clearly see that the plot is symmetric around the point $\rho_n/\rho_p = 1$, which symbolizes isospin symmetric nuclear matter. This means, the in-medium quark condensate behaves the same for a certain ratio $\rho_n/\rho_p$ and for the inverse ratio $(\rho_n/\rho_p)^{-1}$ because of isospin symmetry. This can also be seen on the far left and far right ends of the plot, which correspond to proton matter and neutron matter, respectively. Furthermore, there is no significant effect if we treat protons and neutrons with different masses $m_p \neq m_n$.

For interactions between nucleons the $\Delta$ baryons might be an important ingredient, as suggested by Ref. [12], however in this work we do not consider dynamical $\Delta$ interactions. Since some $\Delta$ contributions are already implicitly included in the low-energy constants, our calculations are expected to be valid as long as dynamical $\Delta$ interactions are not required. Otherwise, one would have to include the $\Delta$ fields in the Lagrangian and investigate their in-medium effects.

We also use isospin-averaged values for the pion mass, $m_\pi = 138$ MeV, and the nucleon mass, $m_N = 939$ MeV.

For the in-medium quark condensate, the integrals in Eqs. (31), (35) and (39) are solved numerically and the result yields the density dependence of the quark condensate, which is presented in Fig. 1. Our computed value of the quark condensate at normal nuclear density, which shows a reduction of 34.3% shows good agreement with Ref. [5], where the in-medium behavior of the quark condensate was shown to be: \( \langle \bar{q}q \rangle^*/\langle \bar{q}q \rangle_0 \approx (b_1/b_1^0)^{1/2}[1-\beta \rho] \approx 1-0.37 \rho/\rho_0 \). Here, the parameters take on the following values $b_1/b_1^0 = 0.79 \pm 0.05$ and $\beta = (2.17 \pm 0.04)$ $\text{fm}^3$, which were obtained from experimental data from deeply bound pionic atoms and isospin-singlet $\pi N$-scattering amplitudes, respectively. Our results are also in good agreement with results obtained in Ref. [12] which are summarized by Ref. [23]. They are also consistent with Ref. [24].

The density dependence of the in-medium quark condensate shows a linear behavior, since the next-to-leading order contributions in the density expansion, which lead to $O(\rho^{1/3})$ and $O(\rho^{5/3})$ behavior, are much smaller. The contributions of the individual diagrams are shown in Fig. 2. The right two figures show that the next-to-leading order diagrams have rather tiny contributions to the quark condensate. This is because the Fermi momentum is small compared to the nucleon mass in low densities and the Fermi motion expansion could be convergent. In this sense, the nucleon-nucleon correlation, which plays a role from $O(\rho^2)$, should be important and bring a new scale parameter.

This work is built on the foundation of Ref. [8], where the in-medium quark condensate was calculated...
Here, $d^{abc}$ are the totally symmetric $SU(3)$ structure constants, given by $4d^{abc} = \text{Tr} \{ \lambda^a \{ \lambda^b, \lambda^c \} \}$, where $\lambda^a$ ($a = 1, \ldots, 8$) are the Gell-Mann matrices. For specific values of $a$ and $b$, this yields:

$$[Q^3_5, P^8(0)] = -\frac{i}{\sqrt{3}} (\bar{u}u - \bar{d}d).$$  \hspace{1cm} (41)$$

In the case of explicit isospin breaking in the Lagrangian due to $m_u \neq m_d$, the PCAC relation changes as follows:

$$\partial^\mu A^3_\mu(x) = mP^3 + \frac{\delta m}{\sqrt{3}} P^0 + \frac{\delta m}{\sqrt{3}} P^8. \hspace{1cm} (42)$$

where $m = (m_u + m_d)/2$ and $\delta m = (m_u - m_d)/2$. This leads to two additional correlation functions necessary in order to compute the density dependence of the quark condensate compared to the $\delta m = 0$ case:

$$\langle \bar{u}u - \bar{d}d \rangle^* = -i\sqrt{3} m \Pi^{\Pi^8}(0)$$

$$- i\sqrt{2} \delta m \Pi^{\Pi^8}(0) - i \delta m \Pi^{\Pi^8}(0). \hspace{1cm} (43)$$

To this end, we devised a similar derivation as shown in Sec. IID.

We use the following Lagrangian:

$$\mathcal{L} = \frac{f^2}{4} \text{Tr} \left\{ D_\mu U^\dagger D^\mu U + \chi^\dagger U + \chi U^\dagger \right\}$$

$$+ b_D \text{Tr} \left\{ \bar{B} \{ \chi^+, B \} \right\} + b_F \text{Tr} \left\{ \bar{B} [ \chi^+, B ] \right\}$$

$$+ b_0 \text{Tr} \left\{ \bar{B} B \right\} \text{Tr} \{ \chi^+ \} + \ldots, \hspace{1cm} (44)$$

where we listed only the terms relevant to this work. One can identify the following relation between $SU(2)$ and $SU(3)$ low energy constants: $2b_0 + b_D + b_F = 2c_1$. Furthermore, there is also a $\pi^0\eta_8$ interaction Lagrangian,

$$\mathcal{L}_{\pi^0\eta_8} = -\frac{2B_0 \delta m}{\sqrt{3}} \pi^0 \eta_8, \hspace{1cm} (45)$$

which allows for $\pi^0\eta_8$ mixing. We regard this mixing as a perturbation and include relevant vertices in the Feynman diagrams. We will in the following consider all diagrams with additional pions coming from this $\pi^0\eta_8$ mixing, since the large mass of the $\eta_8$ leads to a suppression of new $\eta_8$ propagators in the soft limit.

For the chiral field, we use the Coleman–Callan–Wess–Zumino (CCWZ) parametrization:

$$U = \exp \left( \frac{i\sqrt{2} \Phi}{f} \right), \hspace{1cm} (46)$$
The density dependence of \((\bar{u}u - \bar{d}d)^*\) is one order of magnitude smaller than the density dependence of \((\bar{u}u + \bar{d}d)^*\). The vertical grey solid and dotted lines correspond to the same densities and nucleon ratios across the three plots. The dotted green lines correspond to the effects of only the isospin-asymmetric nuclear matter. (a) The dependence of \((\bar{u}u - \bar{d}d)^*\) on the neutron-to-proton ratio. The isospin breaking due to \(\delta m \neq 0\) leads to a reduction of around 1% at normal nuclear density, across all nucleon ratios. (b) The dependence of \((\bar{u}u - \bar{d}d)^*\) on the nucleon density. The three contributions to \((\bar{u}u - \bar{d}d)^*\) as well as their sum are shown. For a nucleon ratio of \(\rho_n/\rho_p = 1.5\), the up and down quark condensates are almost the same. (c) Same as before, here with a ratio \(\rho_n/\rho_p = 10\).

where the meson octet is given as \(\Phi = \Phi^a \lambda^a \sqrt{2}\):

\[
\Phi = \begin{pmatrix}
\frac{\pi^0}{\sqrt{2}} + \frac{\eta}{\sqrt{6}} & \pi^+ & K^+\\
\pi^- & -\frac{\pi^0}{\sqrt{2}} + \frac{\eta}{\sqrt{6}} & K^0\\nK^- & K^0 & \eta
\end{pmatrix},
\]

and the baryon octet as \(B = B^a \lambda^a \sqrt{2}\):

\[
B = \begin{pmatrix}
\frac{\Sigma^0}{2} + \frac{\Lambda}{\sqrt{6}} & \Sigma^+ & \Lambda \\
\Sigma^- & -\frac{\Sigma^0}{2} + \frac{\Lambda}{\sqrt{6}} & n \\
\Xi^- & \Xi^0 & -\frac{2}{\sqrt{6}} \Lambda
\end{pmatrix}.
\]

The \(SU(3)\) equivalent of the chiral field parametrization in Eq. (47) is not known, but since this linear density approximation does not include meson loops, the simpler CCWZ parametrization suffices.

The interaction terms in the Lagrangian that are necessary for the following calculations are listed in Appendix B. The diagrams and their results are:

\[
\Pi^{^{38}}(q) = \pi^8 \rightarrow \eta_8 \cdots \pi^0 \cdots p^3
\]

The isospin breaking in the first and second diagrams is due to \(\rho_p \neq \rho_n\), in the third and fifth diagrams it is due to \(\delta m \neq 0\), and the fourth diagram contains terms from both. Furthermore, the second diagram and the term due to \(\rho_p \neq \rho_n\) in the fourth diagram exactly cancel each other, because the pion mass from the propagator and from the LEC \(B_0\) cancelled out. The correlation function \(\Pi^{^{38}}\) leads to two diagrams:

\[
\Pi^{^{38}}(q) = \pi^8 \rightarrow \eta_8 \cdots \pi^0 \cdots p^3 + \pi^8 \rightarrow \eta_8 \cdots \pi^0 \cdots p^3
\]

These diagrams must be isospin-even. That is because we multiply \(\Pi^{^{38}}\) with \(\delta m\), as stated in Eq. (49). Here, the first diagram contains no isospin breaking. The second diagram breaks isospin twice, once via \(\delta m \neq 0\) and once via \(\rho_p \neq \rho_n\). Hence, this diagram yields a contribution of order \(O(\delta m^2)\) to the quark condensate. The pseudoscalar correlation function \(\Pi^{^{88}}\) can be calculated using these diagrams:

\[
\Pi^{^{88}}(q) = 2 \pi^8 \rightarrow \eta_8 \cdots \pi^0 \cdots p^8 + 2 \pi^8 \rightarrow \eta_8 \cdots \pi^0 \cdots p^8
\]

These diagrams must again be isospin-even, since we multiply \(\Pi^{^{88}}\) with \(\delta m\), as stated in Eq. (49). The first diagram contains no isospin breaking, whereas the second
diagram features isospin breaking due to $\delta m \neq 0$ and $\rho_p \neq \rho_n$. The third diagram contains one term without any isospin breaking and one with double isospin breaking due to $\delta m \neq 0$ and $\rho_p \neq \rho_n$.

In the soft limit and omitting terms beyond $O(p)$ and $O(\delta m)$, which means omitting terms with triple isospin breaking, we get:

$$\sqrt{3} \frac{m\Pi_{58}}{1/(qq)_0} = \frac{2\rho}{f^2} (b_D + b_F) \frac{1 - r}{1 + r}$$

$$- \frac{2\rho}{f^2} (18b_0 + 11b_D + 3b_F) \frac{\delta m}{m + 2m_s}, \quad (52a)$$

$$\sqrt{3} \frac{m\Pi_{88}}{1/(qq)_0} = - \frac{4\rho (b_D - 3b_F)}{f^2} \frac{\delta m}{m + 2m_s}, \quad (52b)$$

$$\frac{\delta m\Pi_{88}}{1/(qq)_0} = \rho \frac{2(9b_0 + 7b_D - 3b_F) + m^2_\eta (b_D - 3b_F)}{m^2_\eta}$$

$$\times \frac{\delta m}{m + 2m_s}. \quad (52c)$$

In agreement with the Vafa–Witten theorem \[28\], our results only depend on the difference of proton and neutron densities in the absence of explicit isospin breaking ($\delta m = 0$), since isospin symmetry is not spontaneously broken in QCD.

For the LECs in the $SU(3)$ Lagrangian, we chose $b_D = 0.225$ GeV$^{-1}$, $b_F = -0.404$ GeV$^{-1}$ and $b_0 = -0.609$ GeV$^{-1}$, which were determined in Ref. \[27\]. There, the values are listed following a calculation of octet $b$-baryon masses using an $SU(3)$ chiral perturbation theory with the extended-on-mass-shell renormalization scheme and fitting the low energy constants to lattice data. Using lattice data, it is possible to determine the parameters $m_0$ (the octet baryon masses in the chiral limit) and $b_0$ separately. Similar values have been reported in Refs. \[29\].

We further used a quark mass ratio of $\delta m/m \approx -1/3$ (equivalent to $m_u/m_d \approx 0.46$) and $m_s/m \approx 27.2$ and the following leading order relations of meson masses with relation to $B_0$:

$$m^2_\pi = 2B_0m, \quad m^2_\eta = \frac{2}{3}B_0(m + 2m_s). \quad (53)$$

with $m_\pi = 138$ MeV and $m_\eta = 548$ MeV.

The results of $\Pi_{58}$, $\Pi_{88}$ and $\Pi_{88}$ are shown in Fig. 4. The density dependence of $\langle \bar{u}u - \bar{d}d \rangle^*$ is one order of magnitude smaller than the density dependence of $\langle \bar{u}u + \bar{d}d \rangle^*$. This is because the coefficient in $\langle \bar{u}u - \bar{d}d \rangle^*$ is smaller by a factor of 10 than the coefficient in $\langle \bar{u}u + \bar{d}d \rangle^*$, as

$$b_D + b_F \approx -0.18 \text{ GeV}^{-1}, \quad (54a)$$

$$2b_0 + b_D + b_F \approx -1.4 \text{ GeV}^{-1}. \quad (54b)$$

We illustrate the effects of explicit isospin breaking by also plotting the result for $\delta m = 0$. Figure 4 (a) shows the dependence of $\langle \bar{u}u - \bar{d}d \rangle^*$ on the neutron-to-proton ratio. The isospin breaking due to $m_u \neq m_d$ leads to a reduction of around 1% at normal nuclear density, almost independent of nucleon ratios. Figure 4 (b) shows the dependence of $\langle \bar{u}u - \bar{d}d \rangle^*$ on the neutron density, in particular the three contributions to $\langle \bar{u}u - \bar{d}d \rangle^*$ as well as their sum are shown. For a nucleon ratio of $\rho_n/\rho_p = 1.5$, the up and down quark condensates are almost the same. Figure 4 (c) also shows the density dependence and was calculated using a nucleon ratio $\rho_n/\rho_p = 10$.

Although the explicit isospin breaking due to unequal quark masses in the Lagrangian provides a numerically smaller effect than the isospin breaking from the surrounding nuclear matter at e.g. $\rho_n/\rho_p = 1.5$,

$$\frac{1}{150} \approx \frac{\delta m}{m + 2m_s} \ll \frac{1 - r}{1 + r} = \frac{1}{5}, \quad (55)$$

this is compensated by the large number of diagrams due to $\delta m \neq 0$, which leads to a large contribution via the LECs:

$$-(b_D + b_F) \frac{1 - r}{1 + r} \approx 0.04 \text{ GeV}^{-1}, \quad (56a)$$

$$(18b_0 + 11b_D + 3b_F) \frac{\delta m}{m + 2m_s} \approx 0.06 \text{ GeV}^{-1}. \quad (56b)$$

Here we note that the coefficients of the LECs in Eq. (56b) are one order of magnitude larger than the ones in Eq. (56a). This is significant, especially since $b_0$ is larger than the other LECs $b_D$ and $b_F$, which gets further enhanced by the factor of 18. Hence, the effects of isospin breaking in the Lagrangian and in the nuclear matter are of similar size in our calculations. Still, there exists a possible ambiguity in the determination of $b_0$, which is often absorbed in the chiral limit octet baryon masses $m_0$. It is possible to extract a value for $b_0$ from scattering experiments, although such experimental data is scarce. Such an issue is absent in the LECs $b_D$ and $b_F$, which are determined via Gell-Mann–Okubo mass relations.

For a nucleon ratio of 1.5, i.e. the one most accessible to experiments via heavy nuclei, the up and down quark condensates behave almost the same with increasing density, see Fig. 4 (a). The effect of explicit isospin breaking in the Lagrangian leads to an almost constant reduction of 1% along all nucleon ratios, but the splitting of up and down quark condensates increases due to the isospin breaking of the surrounding nuclear matter.

It would be interesting to discuss the experimental determination of the coefficients $b_D + b_F$ etc., appearing in our results. As is well-known, the parameter $c_1$ is determined by the $\pi N$-$\sigma$ term, which is obtained by taking the soft limit in $\pi N$ scattering, $\lim_{m_\pi \to 0} T_{\pi N}(p) = -\sigma_{\pi N}/f^2$. In a similar way, the $SU(3)$ coefficients could be extracted from the $N \to \pi^0 N$ scattering amplitudes in the soft limit. Nevertheless, it would be difficult, because the $\eta$ meson mass is so large that a theoretical extrapolation to the soft limit would have a large uncertainty. In addition, in $\eta N \to \pi^0 N$ scattering, the contribution of the $N(1535)$ nucleon resonance is known to dominate the amplitude.
around the threshold. The resonance contribution should therefore be counted in the extrapolation.

V. CONCLUSION

We have calculated the density dependence of the \langle \bar{u}u + \bar{d}d \rangle quark condensate in isospin-asymmetric nuclear matter using an SU(2) in-medium chiral perturbation theory up to second order in the chiral counting. We have found that the reduction of the magnitude of the quark condensate in an isospin asymmetric nuclear matter with \rho_n/\rho_p = 1.5 agrees with the phenomenological result obtained using experimental observations and also previous theoretical estimations. We have also found that the effect of the isospin-asymmetric nuclear matter is weak, but still non-zero. This is because contributions beyond the linear density are rather small due to smaller Fermi motion in low densities. Nucleon-nucleon correlations, which play a role at \mathcal{O}(\rho^2), could contribute to the deviation of the \langle \bar{u}u + \bar{d}d \rangle quark condensate in the symmetric nuclear matter as well as asymmetric nuclear matter from that in the symmetric nuclear matter.

We have also estimated the difference of the up and down quark condensates, \langle \bar{u}u - \bar{d}d \rangle, in leading order of the in-medium chiral perturbation theory by using an SU(3) chiral Lagrangian. The isospin asymmetric nuclear matter as well as \mu_u \neq \mu_d in the Lagrangian provided the splitting of the the up and down quark condensates. We have found, nevertheless, that the magnitude of the splitting is not so large in comparison with the in-medium reduction of the quark condensate \langle \bar{q}q \rangle.

Future works might include nucleon-nucleon interaction terms in the Lagrangian. This would lead to new effects beyond the linear density and a new scale for the density expansion. It should be certainly interesting to perform dynamical calculations in the SU(3) in-medium chiral perturbation theory beyond the linear density approximation.

ACKNOWLEDGEMENTS

We would like to thank Prof. Hosaka for his suggestion to calculate the in-medium density dependence of \langle \bar{u}u - \bar{d}d \rangle. The work of D. J. was partly supported by Grants-in-Aid for Scientific Research from JSPS (17K05449, 21K03530).

Appendix A: Pion-Nucleon Interaction Operator

The \pi N interaction Lagrangian is given by \mathcal{A} = \mathcal{A}^{(1)} + \mathcal{A}^{(2)} + \ldots, where \mathcal{A}^{(1)} is of chiral order \mathcal{O}(\rho^2). The first two terms, \mathcal{A}^{(1)} and \mathcal{A}^{(2)} read:

\begin{equation}
\begin{aligned}
\mathcal{A}^{(1)} &= -i\gamma^\mu \Gamma_\mu - ig_A^\mu \gamma^5 \Delta_\mu, \\
\mathcal{A}^{(2)} &= -c_1 \text{Tr} \{\chi_+\} + \frac{c_2}{2m_N} \text{Tr} \{u_\mu u_\nu\} D_\mu D_\nu \\
&- \frac{c_3}{2} \text{Tr} \{u_\mu u_\nu\} + \frac{c_4}{2} \gamma^\mu \gamma^\nu [u_\mu, u_\nu] - c_5 \chi_+ \\
&- \frac{i c_6}{8m_N} \gamma^\mu \gamma^\nu F_{\mu\nu}^+ - \frac{i c_7}{8m_N} \gamma^\mu \gamma^\nu \text{Tr} \{F_{\mu\nu}^+\}.
\end{aligned}
\end{equation}

Here, we need the definitions of the following terms. The vector current reads:

\begin{equation}
\Gamma_\mu = \frac{1}{2} [u^\dagger, \partial_\mu u] \\
- \frac{i}{2} u^\dagger (v_\mu + a_\mu) u - \frac{i}{2} u (v_\mu - a_\mu) u^\dagger, \tag{A3}
\end{equation}

and the axial-vector current is given by:

\begin{equation}
\Delta_\mu = \frac{1}{2} [u^\dagger, (\partial_\mu - i(v_\mu + a_\mu))] u \\
- \frac{1}{2} u^\dagger [(\partial_\mu - i(v_\mu - a_\mu)) u^\dagger, \tag{A4}
\end{equation}

where \mu^2 = U. Also, \mu_\mu is proportional to the axial-vector current, \mu_\mu = 2i \Delta_\mu. The next terms contain scalar and pseudoscalar sources,

\begin{equation}
\chi_+ = u \chi^\dagger u + u^\dagger \chi u^\dagger, \quad \bar{\chi}_+ = \chi^\dagger - \frac{1}{2} \text{Tr} \{\chi_+\} 1, \tag{A5}
\end{equation}

where \bar{\chi}_+ is the traceless version of \chi_+, i.e. the coefficient in front of the trace is equal to the inverse of Tr \{1\}. The covariant derivative of the nucleon field is given by this expression:

\begin{equation}
D_\mu N = \partial_\mu N + \Gamma_\mu N, \tag{A6}
\end{equation}

where \Gamma_\mu is again the vector current, and finally we include vector and axial-vector sources via:

\begin{equation}
\begin{aligned}
F_{\mu\nu}^+ &= u^\dagger F_{\mu\nu}^R u + u F_{\mu\nu}^L u^\dagger, \\
F_{\mu\nu}^R &= \partial_\mu r_\nu - \partial_\nu r_\mu - i[r_\nu, r_\mu], \\
F_{\mu\nu}^L &= \partial_\mu l_\nu - \partial_\nu l_\mu - i[l_\nu, l_\mu],
\end{aligned} \tag{A7}
\end{equation}

where \mu_\mu = (v_\mu + a_\mu)/2 and \ell_\mu = (v_\mu - a_\mu)/2.

Appendix B: Interaction Terms

In this section, we list all the interactions in the Lagrangian that we use in this work. The particles that interact in the corresponding vertex are indicated via subscripts. First, these are the interactions coming from the chiral Lagrangian in Eq. (16), involving only the pion
field and external sources:

\[
\mathcal{L}_{\pi^i}^{(2)} = 2J_i B_0 \pi^i p^i, \quad \mathcal{L}_{\pi^p}^{(2)} = -\frac{B_0}{5f} \pi^i p^i \pi^j p^j, \quad \mathcal{L}_{\pi^3}^{(2)} = \frac{1}{10f^2} \partial_\mu \pi^i \partial^\mu \pi^j \partial^\nu \pi^k \partial^\lambda \pi^\lambda (3\delta^{ik}\delta^{jl} - \delta^{ij}\delta^{kl})
\]

\[
- \frac{m B_0}{20f^2} \pi^i \pi^j \pi^k,
\]

Using the first term in the expansion of the pion-nucleon interaction operator \(A\) in Eq. (A1), we find the following interactions relevant for this work (note that the only parameter is \(g_A\), the rest is fixed by chiral symmetry; also additionally to the fields indicated in the subscript, a nucleon enters and exits the vertex):

\[
A_{\pi^i}^{(2)} = \frac{g_A}{2f} \gamma^\mu \gamma^5 \partial_\mu \pi^i \pi^i,
\]

\[
A_{\pi^p}^{(1)} = 4 \frac{f}{f^2} \gamma^\mu \gamma^5 \partial_\mu \pi^p \pi^p,
\]

\[
A_{\pi^3}^{(1)} = \frac{g_A}{20f^3} \gamma^\mu \gamma^5 \left[3\pi^i \pi^j \partial_\mu \pi^j - \pi^j \pi^j \partial_\mu \pi^i\right] \pi^i.
\]

From the second term of the pion-nucleon interaction operator, \(A^{(2)}\) in Eq. (A2), we get these interactions:

\[
A_{\pi^i}^{(2)} = -\frac{8c_1 B_0}{f} \pi^i p^i,
\]

\[
A_{\pi^p}^{(2)} = \frac{4c_2}{f} \pi^i \pi^i + \frac{c_3}{f^2 m_N} \partial_\mu \pi^i \partial_\nu \pi^i \partial^\mu \partial^\nu
\]

\[
- \frac{c_3}{f^2} \partial_\mu \pi^i \partial^\nu \pi^i + \frac{ic_4}{f^2} i \epsilon^{ijkl} \gamma^\mu \gamma^\nu \partial_\mu \pi^i \partial_\nu \pi^j,
\]

and we also used the fact that the following vertices do not exist: \(A_{\pi^i}^{(2)} = 0, A_{\pi^p}^{(2)} = 0\).

Interactions obtained from the \(SU(3)\) Lagrangian, Eq. (44), are listed below. The interactions without nucleons are:

\[
\mathcal{L}_{\rho^i \pi^j} = \mathcal{L}_{\rho^i \pi^j} = 2B_0 f
\]

where we also note that \(\mathcal{L}_{\rho^i \pi^j} = \mathcal{L}_{\rho^i \pi^j} = \mathcal{L}_{\rho^i \pi^j} = 0\).

The interactions containing nucleons and external currents are given below. In the following, the upper sign corresponds to a proton (\(\bar{NN} = \bar{pp}\) vertex) and the lower sign corresponds to a neutron (\(\bar{NN} = \bar{nn}\) vertex).

\[
\mathcal{L}_{\bar{NN} p^i \pi^j} = \mathcal{L}_{\bar{NN} p^i \pi^j} = \pm \frac{4B_0 (b_D + b_F)}{\sqrt{3}f}
\]

\[
\mathcal{L}_{\bar{NN} p^i \pi^j} = \frac{4B_0 (6b_0 + 5b_D - 3b_F)}{3f}
\]

\[
\mathcal{L}_{\bar{NN} p^i \pi^j} = \frac{4\sqrt{2}B_0 (b_D - 3b_F)}{3f}
\]

\[
\mathcal{L}_{\bar{NN} p^i \pi^j} = \pm \frac{4\sqrt{2}B_0 (b_D + b_F)}{3f}
\]

and the interactions containing no external currents are:

\[
\mathcal{L}_{\bar{NN} p^i \pi^j} = \mathcal{L}_{\bar{NN} p^i \pi^j} = \frac{4B_0 (b_D + b_F)}{\sqrt{3}f^2} + \frac{4B_0 m(b_D + b_F)}{\sqrt{3}f^2}
\]

\[
\mathcal{L}_{\bar{NN} p^i \pi^j} = \frac{2B_0 [m(2b_0 + b_D + b_F) + 4m_x(b_0 + b_D - b_F)]}{3f^2} + \frac{2B_0 m(b_D + b_F)}{3f^2}
\]

Note that the terms in Eq. (B6a) break isospin either via non-equal quark masses \(\delta m \neq 0\) or via the isospin asymmetry of the nuclear matter (expressed by the different signs in proton and neutron interactions), while Eq. (B6b) is isospin-even.
