Abstract   A collector samples coupons with replacement from a pool containing $g$ uniform groups of coupons, where “uniform group” means that all coupons in the group are equally likely to occur (while coupons of different groups have different probabilities to occur). For each $j = 1, \ldots, g$, let $T_j$ be the number of trials needed to detect Group $j$, namely to collect all $M_j$ coupons belonging to it at least once. We first derive formulas for the probabilities $P\{T_1 < \cdots < T_g\}$ and $P\{T_1 = \bigwedge_{j=1}^g T_j\}$. After that, without severe loss of generality, we restrict ourselves to the case $g = 2$ and compute the asymptotics of $P\{T_1 < T_2\}$ as the number of coupons grows to infinity in a certain manner. Then, we focus on $T := T_1 \lor T_2$, i.e. the number of trials needed to collect all coupons of the pool (at least once), and determine the asymptotics of $E[T]$ and $V[T]$, as well as the limiting distribution of $T$ (appropriately normalized) as the number of coupons becomes large.

1 Introduction of the Problem and Main Results

Coupon collector problems (CCP’s) are a popular class of urn problems due to their mathematical elegance, as well as their applications in several areas of science, from computer science and biology to linguistics and the social sciences. The original problem dates back to De Moivre’s treatise *De Mensura Sortis* (1712) and Laplace’s *Theorie Analytique des Probabilités* (1812). Nevertheless, new variants of CCP keep arising. For the history of (CCP) see, e.g., [6] and the references therein.

In this paper we study the following CCP version: Suppose we sample coupons independently with replacement from a mixture of $g$ groups of coupons. The first group consists of $M_1$ coupons each of which having probability $p_1$ to occur, the second group of $M_2$ coupons each of which having probability $p_2$ to occur, and so on (all numbers $M_j$, $p_j$, $j = 1, \ldots, g$, are assumed strictly positive). We call “Group $j$ coupons” the coupons of the $j$-th group. Notice that under
our assumptions we must have
\[ M_1 p_1 + \cdots + M_g p_g = 1. \]  
\[ (1.1) \]
Thus, for each \( j = 1, \ldots, g \), the \( j \)-th group is a uniform family of \( M_j \) coupons, where the term “uniform” indicates that all coupons of the group have the same probability \( p_j \) to occur. For instance, we can visualize Group 1 as a set of \( M_1 \) cards of color 1 (say red), numbered from 1 to \( M_1 \), Group 2 as a set of \( M_2 \) cards of color 2 (say green), numbered from 1 to \( M_2 \), and so on, where each card of color 1 has probability \( p_1 \) to occur, each card of color 2 has probability \( p_2 \) to occur, and so on.

Suppose we keep drawing coupons one at a time. Naturally, one quantity of interest is the number \( T \) of trials (i.e. draws) needed to detect all \( M_1 + \cdots + M_g \) coupons (at least once). Some “intermediate” quantities having their own interest are \( T_j := \) the number of trials needed to detect all Group \( j \) coupons, \( j = 1, \ldots, g \). Clearly, \( T \) can be expressed as
\[ T = \bigvee_{j=1}^g T_j, \]
\[ (1.2) \]
namely the maximum of \( T_1, \ldots, T_g \).

It is worth mentioning that if we view the coupon sampling process as a sequence \( \{C_n\}_{n \geq 1} \) of independent and identically distributed random variables, where each \( C_n \) takes values in \( \{1, 2, \ldots, (M_1 + \cdots + M_g)\} \), namely the set of all existing coupons, with \( P\{C_n = i_1\} = p_1 \) for \( i_1 = 1, 2, \ldots, M_1 \), \( P\{C_n = i_2\} = p_2 \) for \( i_2 = (M_1 + 1), (M_1 + 2), \ldots, (M_1 + M_2) \), and so on (so that, \( \{C_n = i\} \) is identified with the event that the type-\( i \) coupon is selected at the \( n \)-th trial), then \( T_j, j = 1, \ldots, g \), as well as \( T \) are stopping times of the “coupon filtration”
\[ \mathcal{F}_n = \sigma(C_1, \ldots, C_n), \quad n \geq 1. \]  
\[ (1.3) \]
Our first quantities of study are \( P\{T_1 < \cdots < T_g\} \) and \( P\{T_1 = T_{\min}\} \), where
\[ T_{\min} := \bigwedge_{j=1}^g T_j, \]  
\[ (1.4) \]
namely the minimum of \( T_1, \ldots, T_g \) (thus \( P\{T_1 = T_{\min}\} \) is the probability that Group 1 is the first group to be detected in its entirety). Notice that the equality \( T_j = T_k \) is impossible unless, of course, \( j = k \).

**Theorem 1.1**
\[ P\{T_1 < \cdots < T_g\} = K \int_0^\infty \cdots \int_0^{t_3} e^{-(p_1 t + \cdots + p_2 t_2)} (1 - e^{-p_2 t_2}) M_1 - 1 \cdots \times (1 - e^{-p_2 t_2}) M_2 - 1 (1 - e^{-p_1 t_2}) M_3 dt_2 \cdots dt_g, \]  
\[ (1.5) \]
where
\[ K = p_2 p_3 \cdots p_g M_2 M_3 \cdots M_g. \]  
\[ (1.6) \]
Also,
\[ P\{T_1 = T_{\min}\} = K \int_0^\infty \cdots \int_0^\infty e^{-(p_1 t + \cdots + p_2 t_2)} (1 - e^{-p_2 t_2}) M_2 - 1 \cdots \times (1 - e^{-p_2 t_2}) M_2 - 1 (1 - e^{-p_1 (t_2 \wedge \cdots t_g)}) M_1 dt_2 \cdots dt_g. \]  
\[ (1.7) \]
The proof of the theorem is based in the powerful technique of Poissonization and is included in Appendix.

Notice that one consequence of formulas (1.5), (1.6), and (1.7) is that the probabilities \( P\{T_1 < \cdots < T_g\} \) and \( P\{T_1 = T_{\min}\} \) depend only on the ratios \( p_2/p_1, \ldots, p_g/p_1 \).

**Corollary 1.2** For \( \ell = 1, \ldots, g \), we have

\[
P\{T_\ell = T_{\min}\} = (-1)^g \sum_{k_g=1}^{M_g} \cdots \sum_{k_1=1}^{M_1} (-1)^{k_1 + \cdots + k_g} \binom{M_1}{k_1} \cdots \binom{M_g}{k_g} \frac{k_\ell p_\ell}{k_1 p_1 + \cdots + k_g p_g}.
\]

(1.8)

In particular, for \( g = 2 \), we have

\[
P\{T_1 < T_2\} = \sum_{k=1}^{M_2} \sum_{j=1}^{M_1} (-1)^{j+k} \binom{M_1}{j} \binom{M_2}{k} \frac{p_1 j}{p_1 j + p_2 k},
\]

(1.9)

and

\[
P\{T_2 < T_1\} = \sum_{k=1}^{M_2} \sum_{j=1}^{M_1} (-1)^{j+k} \binom{M_1}{j} \binom{M_2}{k} \frac{p_2 k}{p_1 j + p_2 k}.
\]

(1.10)

The proof is included in Appendix.

We can number the groups so that \( p_1 < p_2 < \cdots < p_g \). Then, our CCP problem is stochastically bounded between two “extreme” cases where we have only two groups of coupons: (i) one group consisting of \( M_1 \) coupons each of which having probability \( p_1 \) to occur and another group consisting of \( M_2 + \cdots + M_g \) coupons each of which having probability \( p_2 \) to occur and (ii) one group consisting of \( M_1 \) coupons each of which having probability \( p_1 \) to occur and another group consisting of \( M_2 + \cdots + M_g \) coupons each of which having probability \( p_g \) to occur. Hence, the case \( g = 2 \) is quite important since it can, at least, provide upper and lower estimates for the more general case of an arbitrary number of groups. With this in mind, let us spell out an immediate corollary of Theorem 1.1.

**Corollary 1.3** We have

\[
P\{T_1 < T_2\} = p_2 M_2 \int_0^\infty e^{-p_2 t}(1 - e^{-p_1 t})^{M_1}(1 - e^{-p_2 t})^{M_2 - 1} dt.
\]

(1.11)

Also (by substitution \( x = e^{-t} \) in the above integral),

\[
P\{T_1 < T_2\} = p_2 M_2 \int_0^1 (1 - x^{p_1})^{M_1} (1 - x^{p_2})^{M_2 - 1} x^{p_2 - 1} dx = - \int_0^1 (1 - x^{p_1})^{M_1} [(1 - x^{p_2})^{M_2}]' dx.
\]

(1.12)

The observation that \( P\{T_1 < T_2\} \) depends only on the ratio

\[
\lambda := \frac{p_2}{p_1}
\]

(1.13)

yields two slightly simplified equivalent versions of (1.12), namely

\[
P\{T_1 < T_2\} = \lambda M_2 \int_0^1 x^{\lambda - 1}(1 - x)^{M_1}(1 - x^{\lambda})^{M_2 - 1} dx.
\]

(1.14)
and

$$P\{T_1 < T_2\} = M_2 \int_0^1 (1 - x^{1/\lambda})^{M_1} (1 - x)^{M_2 - 1} \, dx$$  \hspace{1cm} (1.15)$$

(formula (1.11) also can be simplified a little by using the fact that \(P\{T_1 < T_2\}\) depends only on \(\lambda\)).

In the sequel, we will assume that \(g = 2\), namely that we have only two groups of coupons. Our goal is to understand the behavior of certain quantities as \(\lambda = p_2/p_1\) stays fixed, while \(M_1\) and \(M_2\) become large in such a way that

$$M_1 = \nu_1 M \quad \text{and} \quad M_2 = \nu_2 M,$$

where \(\nu_1 \geq 1\) and \(\nu_2 \geq 1\) are fixed integers, while the integer \(M\) is allowed to grow. Notice that, under these assumptions \(p_1\) and \(p_2\) depend on \(M\). Then, recalling (1.1), namely that

$$M_1 p_1 + M_2 p_2 = 1,$$

the quantities

$$\alpha_1 := M_1 p_1 = \frac{\nu_1}{\nu_1 + \lambda \nu_2} \quad \text{and} \quad \alpha_2 := M_2 p_2 = \frac{\lambda \nu_2}{\nu_1 + \lambda \nu_2} = 1 - \alpha_1$$

are independent of \(M\) too.

1.1 Overview of Main Results

In the rest of the paper we study the asymptotic behavior of certain quantities related to \(T_1 = T_1(M),\ T_2 = T_2(M),\) and \(T = T(M) = T_1 \lor T_2,\) as the integer \(M\) grows large. It is notable that our results determine the order of magnitude of the corresponding quantities for the case of \(g\) groups, for any \(g > 2.\)

In Section 2 we derive the asymptotic formula (Theorem 2.1)

$$P\{T_1 < T_2\} \sim \frac{\nu_2 \Gamma(\lambda)}{\nu_1^\lambda} \cdot \frac{1}{M^{\lambda-1}}, \quad M \to \infty,$$

under the assumption that \(\lambda\) of (1.13) is > 1 (as usual, the notation \(f(M) \sim g(M)\) means that \(f(M)/g(M) \to 1\) as \(M \to \infty\)).

Section 3 contains some auxiliary topics including a key example discussed in Subsection 3.1. These topics are used in Section 4 in order to determine the asymptotic behavior of the expectation, the variance, as well as the distribution of \(T_1, T_2,\) and \(T\) as \(M \to \infty.\) Some indicative results of Section 4 are:

(i) A formula for the asymptotics of the expectation of \(T\)

$$E[T] = (\nu_1 + \lambda \nu_2)M \ln M + (\nu_1 + \lambda \nu_2)(\gamma + \ln \nu_1)M + O(M^{2-\lambda} \ln M), \quad M \to \infty.$$ 

This formula follows immediately from Theorem 4.5.

(ii) A formula for the asymptotics of the variance of \(T\)

$$V[T] \sim \frac{\pi^2 (\nu_1 + \lambda \nu_2)^2}{6} M^2, \quad M \to \infty$$

(this is Corollary 4.7).

(iii) The limiting distribution of \(T\) (appropriately normalized). We have shown that the random variable

$$\frac{T - (\nu_1 + \lambda \nu_2)M \ln M}{(\nu_1 + \lambda \nu_2)M} - \ln \nu_1$$
converges in distribution to the standard Gumbel random variable as \( M \to \infty \) (Theorem 4.8).

The above three results are presented in Subsection 4.2 and hold under the assumption that \( \lambda > 1 \).

Finally, for the betterment of the flow of the paper, the derivations of formulas (3.21) and (3.63) are placed in Appendix (Section 5).

2 Asymptotics of \( P\{T_1 < T_2\} \)

The main task of this section is the asymptotics for \( P\{T_1 < T_2\} \) as \( M \to \infty \), under the assumption that \( \lambda \) of (1.13) is \( \lambda > 1 \). Equation (1.14) can be written as

\[
P\{T_1 < T_2\} = \lambda \nu_2 M I_M, \quad \text{where } I_M = \int_0^1 x^{\lambda-1}(1-x)^{\nu_1 M}(1-x^\lambda)^{\nu_2 M-1} dx. \tag{2.1}
\]

Thus, the asymptotic behavior of \( P\{T_1 < T_2\} \) as \( M \to \infty \) reduces to the asymptotic behavior of \( I_M \).

For convenience, we will assume from now on, without loss of generality, that

\[
\frac{\nu_2}{\lambda} > 1. \tag{2.2}
\]

Formula (2.1) yields immediately the following upper bound for \( I_M \):

\[
I_M < \int_0^1 x^{\lambda-1}(1-x)^{\nu_1 M} dx = B(\lambda, \nu_1 M + 1) = \frac{\Gamma(\nu_1 M + 1)}{\Gamma(\lambda + \nu_1 M + 1)}, \tag{2.3}
\]

where \( B(\cdot, \cdot) \) and \( \Gamma(\cdot) \) denote the Beta and Gamma function respectively, while an immediate consequence of Stirling’s formula is that

\[
\int_0^1 x^{\lambda-1}(1-x)^{\nu_1 M} dx = \frac{\Gamma(\nu_1 M + 1)}{\Gamma(\lambda + \nu_1 M + 1)} \sim \frac{\Gamma(\lambda)}{\nu_1^\lambda} \cdot \frac{1}{M^\lambda}, \quad M \to \infty. \tag{2.4}
\]

Next, we need to find a satisfactory lower bound for \( I_M \). Let \( 0 < \varepsilon < 1 - (1/\lambda) \), so that \( (1/\lambda) + \varepsilon < 1 \). Then, (2.1) implies

\[
I_M > I_M^\lambda := \int_0^M x^{\lambda-1}(1-x)^{\nu_1 M}(1-x^\lambda)^{\nu_2 M-1} dx. \tag{2.5}
\]

For \( x \in [0, M^{-(1/\lambda)-\varepsilon}] \), we have

\[
0 \geq (\nu_2 M - 1) \ln(1-x^\lambda) \geq (\nu_2 M - 1) \ln \left(1 - \frac{1}{M^{1+\lambda\varepsilon}}\right) = - \frac{\nu_2}{M^{1+\lambda\varepsilon}} + O\left(\frac{1}{M^{1+\lambda\varepsilon}}\right) \tag{2.6}
\]

as \( M \to \infty \) (uniformly in \( x \)). Hence

\[
1 \geq (1-x^\lambda)^{\nu_2 M-1} \geq \exp\left(- \frac{\nu_2}{M^{1+\lambda\varepsilon}}\right) \left[1 + O\left(\frac{1}{M^{1+\lambda\varepsilon}}\right)\right] = 1 + O\left(\frac{1}{M^{1+\lambda\varepsilon}}\right). \tag{2.7}
\]

Using (2.7) in (2.5) yields

\[
\int_0^{M^{-(1/\lambda)-\varepsilon}} x^{\lambda-1}(1-x)^{\nu_1 M} dx \geq I_M^\lambda \geq \left[1 + O\left(\frac{1}{M^{1+\lambda\varepsilon}}\right)\right] \int_0^{M^{-(1/\lambda)-\varepsilon}} x^{\lambda-1}(1-x)^{\nu_1 M} dx \tag{2.8}
\]

or

\[
I_M^\lambda \sim \int_0^{M^{-(1/\lambda)-\varepsilon}} x^{\lambda-1}(1-x)^{\nu_1 M} dx, \quad M \to \infty. \tag{2.9}
\]
Finally, we notice that the fact that $(1/\lambda) + \varepsilon < 1$ implies for any $r > 0$,

$$\int_{M^{-1/(\lambda+\varepsilon)}}^{1} x^{\lambda-1}(1-x)^{\nu_1 M} \, dx < \left(1 - \frac{1}{M^{1/(\lambda+\varepsilon)}}\right)^{\nu_1 M} = O\left(\frac{1}{M^r}\right). \quad (2.10)$$

Thus, in view of (2.4), formulas (2.9) and (2.10) give

$$I_M^p \sim \int_0^1 x^{\lambda-1}(1-x)^{\nu_1 M} \, dx \sim \frac{\Gamma(\lambda)}{\nu_1^p} \cdot \frac{1}{M^\lambda}, \quad M \to \infty. \quad (2.11)$$

Hence, the combination of (2.3), (2.4), (2.5), and (2.11) yields

$$I_M \sim \frac{\Gamma(\lambda)}{\nu_1^p} \cdot \frac{1}{M^\lambda}, \quad M \to \infty. \quad (2.12)$$

Therefore, by applying (2.12) in (2.1) we obtain the following result.

**Theorem 2.1** If $\lambda = p_2/p_1 > 1$, then

$$P\{T_1 < T_2\} \sim \frac{\nu_2 \Gamma(\lambda)}{\nu_1^p} \cdot \frac{1}{M^{\lambda-1}} = \frac{\nu_2 \Gamma(\lambda+1)}{\nu_1^p} \cdot \frac{1}{M^{\lambda-1}} = \frac{\nu_2}{\nu_1} \cdot \frac{\Gamma(\lambda+1)}{\Gamma(\lambda)} \cdot \frac{1}{M^{\lambda-1}} \quad (2.13)$$

as $M \to \infty$.

Notice that, no matter how big the ratio $M_2/M_1 = \nu_2/\nu_1$ is, the probability $P\{T_1 < T_2\}$ approaches 0 as $M \to \infty$, as long as $\lambda$ is bigger than 1 (even slightly).

### 3 Auxiliary Material

Section 3 contains some auxiliary topics including a key example discussed in Subsection 3.1. These topics are used in Section 4 in order to obtain the main results of the paper.

Suppose we sample independently with replacement from a pool of $N$ coupons, where the probability of the $j$-th coupon to occur is $q_j$, $j = 1, \ldots, N$ (the $q_n$’s are usually referred as the “coupon probabilities”). Let $S = S_N$ denote the number of trials needed in order to detect all $N$ coupons. Obviously, the possible values of $S_N$ are $N, N+1, \ldots$ (it is easy to see that $P\{S_N < \infty\} = 1$ as long as $q_j > 0$ for all $j$; actually, from the generating function $E[z^{-S_N}]$, as computed in [4], one can easily see that $P\{S_N = k\}$ decay exponentially as $k \to \infty$).

For the purposes of this paper, we will need a formula for the expectation $E[S_N^{(r)}]$ for any real $r > 0$, where

$$s^{(r)} := \frac{\Gamma(s+r)}{\Gamma(s)} \quad (3.1)$$

is the “natural” extension of the so-called Pochhammer function.

If we denote by $W_j$ the number of trials needed in order to detect the $j$-th coupon, then, it is clear that $W_j$ is a geometric random variable with parameter $q_j$ and

$$S_N = \sum_{j=1}^{N} W_j.$$

However, the above formula for $S_N$ is not very useful, since the $W_j$’s are not independent. Instead, we can employ again the “Poissonization technique” (see, e.g., [9]) in order to get an explicit formula for $E[S_N^{(r)}]$.

As in the proof of Theorem 1.1, we take $Z(t), t \geq 0$, to be a Poisson process with rate $\lambda = 1$. We imagine that each Poisson event associated to $Z$ is a collected coupon, so that $Z(t)$
is the number of detected coupons at time \( t \). Next, for \( j = 1, \ldots, N \), let \( Z_j(t) \) be the number of times that the \( j \)-th coupon has been detected up to time \( t \). Then, the processes \( \{Z_j(t)\}_{t \geq 0} \) are independent Poisson processes with rates \( q_j \) respectively \[9\] and, of course, \( Z(t) = Z_1(t) + \cdots + Z_N(t) \). If \( X_j, j = 1, \ldots, N \), denotes the time of the first event of the process \( Z_j \), then \( X_1, \ldots, X_N \) are obviously independent (being associated to independent processes), while their maximum

\[
X = \bigvee_{j=1}^{N} X_j
\]  

(3.2)
is the time when all different coupons have been detected at least once.

Next, for each \( j = 1, \ldots, N \), the random variable \( X_j \) is exponentially distributed with parameter \( q_j \), i.e.,

\[
P\{X_j \leq t\} = 1 - e^{-q_j t}, \quad t \geq 0.
\]  

(3.3)

It follows from (3.2) and the independence of the \( X_j \)'s that

\[
P\{X \leq t\} = \prod_{j=1}^{N} (1 - e^{-q_j t}), \quad t \geq 0.
\]  

(3.4)

Next, we observe that \( S_N \) and \( X \) are related as

\[
X = S_N \sum_{k=1}^{m} U_k,
\]  

(3.5)

where \( U_1, U_2, \ldots \) are the interarrival times of the process \( Z \). It is common knowledge that the \( U_j \)'s are independent and exponentially distributed random variables with parameter 1. Hence for any integer \( m \geq 1 \) the sum \( U_1 + \cdots + U_m \) follows the Erlang distribution with parameters \( m \) and 1. Therefore,

\[
E \left[ \phi \left( \sum_{k=1}^{m} U_k \right) \right] = \int_{0}^{\infty} \phi(\xi) \frac{\xi^{m-1}}{(m-1)!} e^{-\xi} d\xi,
\]  

(3.6)

where \( \phi(x) \) is any (Lebesgue) measurable function on \((0, \infty)\) for which the integral in (3.6) makes sense (i.e. converges absolutely). Noticing that \( S_N \) is independent of the \( U_j \)'s, formulas (3.5) and (3.6) imply

\[
E[\phi(X) | S_N] = \int_{0}^{\infty} \phi(\xi) \frac{\xi^{S_N-1}}{(S_N-1)!} e^{-\xi} d\xi
\]  

(3.7)

and, consequently (by taking expectations)

\[
E[\phi(X)] = E \left[ \int_{0}^{\infty} \phi(\xi) \frac{\xi^{S_N-1}}{(S_N-1)!} e^{-\xi} d\xi \right].
\]  

(3.8)

If we take \( \phi(x) = x^{r} \) for a fixed real number \( r > 0 \), then (3.8) becomes

\[
E[X^{r}] = E \left[ \int_{0}^{\infty} \frac{\xi^{S_N+r-1}}{(S_N-1)!} e^{-\xi} d\xi \right] = E \left[ \frac{\Gamma(S_N+r)}{(S_N-1)!} \right] = E[S_N^{(r)}].
\]  

(3.9)

Finally, by using (3.4) in (3.9) we obtain the following result.

**Lemma 3.1** For any real number \( r > 0 \), we have

\[
E[S_N^{(r)}] = E \left[ \frac{\Gamma(S_N+r)}{\Gamma(S_N)} \right] = r \int_{0}^{\infty} t^{r-1} \left[ 1 - \prod_{j=1}^{N} (1 - e^{-q_j t}) \right] dt.
\]  

(3.10)
In particular, for \( r = 1 \), we have
\[
E[S_N] = \int_{0}^{\infty} \left[ 1 - \prod_{j=1}^{N} \left( 1 - e^{-q_j t} \right) \right] dt,
\]
while for \( r = 2 \), we have
\[
E[S_N^{(2)}] = E[S_N(S_N + 1)] = 2 \int_{0}^{\infty} t \left[ 1 - \prod_{j=1}^{N} \left( 1 - e^{-q_j t} \right) \right] dt.
\]

**Remark 3.2** Let the random variables \( \Xi_1, \ldots, \Xi_N \) be independent and exponentially distributed with parameters \( q_1, \ldots, q_N \) respectively. If
\[
\Xi_{\text{max}} := \max_{j=1}^{N} \Xi_j,
\]
then formula (3.10) tells us that for any real number \( r > 0 \), we have
\[
E[S_N^{(r)}] = \frac{\Gamma(S_N + r)}{\Gamma(S_N)} = E[\Xi_{\text{max}}^r].
\]

Let us also notice that by expanding the product inside the integral in (3.10) and integrate the resulting sum term by term we obtain the expression
\[
E[S_N^{(r)}] = \Gamma(r + 1) \sum_{J \subseteq \{1, \ldots, N\}, J \neq \emptyset} \frac{(-1)^{|J|-1}}{(\sum_{j \in J} q_j)^r}
= \Gamma(r + 1) \sum_{m=1}^{N} (-1)^{m-1} \sum_{1 \leq j_1 < \cdots < j_m \leq N} \frac{1}{(q_{j_1} + \cdots + q_{j_m})^r},
\]
where \(|J|\) denotes the cardinality of \( J \).

**Remark 3.3** Let us first observe that since \( S_N \) is always a positive integer, the quantity
\[
\frac{\Gamma(r + S_N)}{\Gamma(r) \Gamma(S_N)}
\]
makes sense for every \( r \in \mathbb{C} \); actually, it is entire in \( r \) (the poles of \( \Gamma(r + S_N) \) are cancelled by the zeros of \( \Gamma(r)^{-1} \)).

Now, let us look at the function
\[
H(r) := \frac{1}{\Gamma(r)} E[S_N^{(r)}] = E\left[ \frac{\Gamma(r + S_N)}{\Gamma(r) \Gamma(S_N)} \right] = \sum_{k=N}^{\infty} \frac{\Gamma(k + r)}{\Gamma(r) (k - 1)!} P\{S_N = k\}.
\]
Since (i) \( \Gamma(k + r)/(k - 1)! \sim k^r \) as \( k \to \infty \) (see, e.g., formula (3.27) below) and (ii) \( P\{S_N = k\} \) decays exponentially in \( k \), it follows that the series in (3.15) converges uniformly (and absolutely) in \( r \) on any compact subset of the complex plane \( \mathbb{C} \). Therefore, \( H(r) \) is an entire function and consequently formula (3.15) implies that \( E[S_N^{(r)}] \) is meromorphic in \( r \) whose poles are located at \(-N, -(N + 1), \ldots \). Although the fact that \( E[S_N^{(r)}] \) is meromorphic also follows from (3.13), it is not obvious from this formula that there are no poles at \(-1, -2, \ldots, -(N - 1)\).

Now let us consider the “uniform” case, namely the case where all \( N \) coupons are equally likely to occur, i.e.,
\[
q_j = \frac{1}{N} \quad \text{for } j = 1, \ldots, N.
\]
In this case formula (3.10) becomes
\[
E[S_N^{(r)}] = r \int_0^\infty t^{r-1} [1 - (1 - e^{-t/N})^N] dt. \tag{3.17}
\]
Substituting \( t = Ns \) in the above integral gives
\[
E[S_N^{(r)}] = N^r \int_0^\infty rs^{r-1} [1 - (1 - e^{-s})^N] ds. \tag{3.18}
\]
Next, we integrate by parts and get
\[
E[S_N^{(r)}] = N^{r+1} \int_0^\infty s^r (1 - e^{-s})^{N-1} e^{-s} ds. \tag{3.19}
\]
Then, we make the substitution \( s = \ln N - \ln x \) (so that \( x = Ne^{-s} \)) in the integral of (3.19) and obtain
\[
E[S_N^{(r)}] = N^r \ln N \int_0^N \left( 1 - \frac{x}{N} \right)^{N-1} \left( 1 - \frac{\ln x}{\ln N} \right)^r dx. \tag{3.20}
\]
Starting from (3.20), it can be shown that, for any given \( r > 0 \), the asymptotic behavior of \( E[S_N^{(r)}] \) as \( N \to \infty \) is
\[
E[S_N^{(r)}] = N^r (\ln N)^r \sum_{k=0}^n \binom{r}{k} \frac{(-1)^k \Gamma(k)(1)}{\ln^k N} \int_0^\infty e^{-x} (\ln x)^k dx + o\left(\frac{1}{\ln^n N}\right) \tag{3.21}
\]
for every \( n = 1, 2, \ldots \) (the proof is included in Subsection 5.3 of Appendix). Here, \( \binom{r}{k} \) stands for the generalized binomial coefficient (in the sense that \( r \) is not necessarily a positive integer — see formulas (5.30) and (5.31) in Subsection 5.1 of Appendix).

Intuitively, it is not hard to see why (3.20) implies (3.21). However, the complete proof is quite long and for this reason is given in the Subsection 5.3 of Appendix.

To further simplify (3.21), let us first notice that if we differentiate \( k \) times the Gamma function \( \Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt \) and then set \( z = 1 \), we get
\[
\Gamma^{(k)}(1) = \int_0^\infty e^{-x} (\ln x)^k dx. \tag{3.22}
\]
Of course, \( \Gamma^{(0)}(1) = \Gamma(1) = 1 \). As for the derivatives \( \Gamma^{(k)}(1) \), \( k = 1, 2, \ldots \), there are some known expressions and recursions (see, e.g., [2] and the references therein). For instance,
\[
\Gamma^{(1)}(1) = -\gamma, \quad \Gamma^{(2)}(1) = \frac{\pi^2}{6} + \gamma^2, \quad \Gamma^{(3)}(1) = - \left[ 2\zeta(3) + \frac{\pi^2}{2} \gamma + \gamma^3 \right], \quad \text{etc.,} \tag{3.23}
\]
where \( \gamma = 0.5772 \ldots \) is the Euler (or Euler–Macheroni) constant and \( \zeta(\cdot) \) is the Riemann Zeta function.

Using (3.22) we can write (3.21) as
\[
E[S_N^{(r)}] = N^r (\ln N)^r \sum_{k=0}^n \binom{r}{k} \frac{(-1)^k \Gamma^{(k)}(1)}{\ln^k N} + o\left(\frac{1}{\ln^n N}\right), \quad N \to \infty, \tag{3.24}
\]
for every \( n = 1, 2, \ldots \). Formula (3.24) can be written equivalently as an asymptotic series (for the definition of the asymptotic series and the associated usage of the symbol \( \sim \) see, e.g., [1])
\[
E[S_N^{(r)}] \sim N^r (\ln N)^r \sum_{k=0}^\infty \binom{r}{k} \frac{(-1)^k \Gamma^{(k)}(1)}{\ln^k N}, \quad N \to \infty, \tag{3.25}
\]
for any \( r > 0 \) (of course, if \( r \) is an integer, \( \binom{k}{r} = 0 \) for \( k > r \) and the series becomes a finite sum). In particular, the leading behavior of \( E[S_N^{(r)}] \) is

\[
E[S_N^{(r)}] \sim N^r (\ln N)^r, \quad N \to \infty.
\]

(3.26)

Let us also mention that in the case where \( r \) is a positive integer there are more detailed expressions for \( E[S_N^{(r)}] \) (see, e.g., [4] and the references therein).

Finally, from (3.26) we can easily obtain an asymptotic formula for \( E[S_N^{(r)}] \) as \( N \to \infty \). For a fixed \( r > 0 \), Stirling’s formula yields

\[
s^{(r)} = \frac{\Gamma(s + r)}{\Gamma(s)} \sim s^r, \quad s \to \infty.
\]

(3.27)

Since \( S_N \geq N \), formula (3.28) implies that, for any \( \epsilon > 0 \) there is an \( N_0 = N_0(\epsilon) \) such that

\[
(1 - \epsilon) S_N^{(r)} \leq S_N^r \leq (1 + \epsilon) S_N^{(r)} \quad \text{for any } N \geq N_0,
\]

(3.28)

and consequently,

\[
(1 - \epsilon) E[S_N^{(r)}] \leq E[S_N^r] \leq (1 + \epsilon) E[S_N^{(r)}] \quad \text{for any } N \geq N_0,
\]

(3.29)

i.e., in view of (3.26),

\[
E[S_N^r] \sim E[S_N^{(r)}] \sim N^r (\ln N)^r, \quad N \to \infty,
\]

(3.30)

for any \( r > 0 \).

3.1 A Preliminary Example

In this part of the paper we deal with a key example. Suppose our set of coupons is \( \{0, 1, \ldots, N\} \) with corresponding probabilities

\[
q_0 = \theta \quad \text{and} \quad q_j = \frac{1 - \theta}{N}, \quad j = 1, \ldots, N,
\]

(3.31)

where \( \theta \in (0, 1) \) is a given number. Let \( S(\theta) = S(\theta; N) \) be the number of trials needed until all \( N + 1 \) coupons are detected (thus \( S(\theta; N) = S_{N+1} \) under the previous notation).

The main results of this subsection are the asymptotics of the expectation, the rising moments, the variance, and finally, the limiting distribution of the random variable \( S(\theta) = S(\theta; N) \). Then, (3.11) gives (in the sequel, the dependence of \( S(\theta) \) on \( N \) will be suppressed for typographical convenience)

\[
E[S(\theta)] = \int_0^\infty \left[ 1 - (1 - e^{-\theta t})(1 - e^{-(1-\theta)t/N})^N \right] dt
\]

or

\[
E[S(\theta)] = J_1(N; \theta) + J_2(N; \theta),
\]

(3.32)

where

\[
J_1(N; \theta) := \int_0^\infty \left[ 1 - (1 - e^{-(1-\theta)t/N})^N \right] dt
\]

(3.33)

and

\[
J_2(N; \theta) := \int_0^\infty e^{-\theta t}(1 - e^{-(1-\theta)t/N})^N dt.
\]

(3.34)
The integral $J_1(N; \theta)$ of (3.33) reminds the expectation of $S_N$ in the case where all $N$ coupons are equally likely to occur. This is very easy to see via the substitution $y = 1 - e^{-(1-\theta)t/N}$ which yields
\[
J_1(N; \theta) = \frac{N}{1-\theta} \int_0^1 \frac{1-y^N}{1-y} \, dy = \frac{N}{1-\theta} \int_0^1 \left( \sum_{j=0}^{N-1} y^j \right) \, dy = \frac{N}{1-\theta} \sum_{j=1}^N \frac{1}{j},
\] (3.35)

or
\[
J_1(N; \theta) = \frac{NH_N}{1-\theta}, \quad \text{where } H_N := \sum_{j=1}^N \frac{1}{j}.
\] (3.36)

The quantity $H_N$ is called the $N$-th harmonic number and its full asymptotic expansion, as $N \to \infty$, is well known (see, e.g., [1]):
\[
H_N \sim \ln N + \gamma + \frac{1}{2N} + \sum_{k=1}^{\infty} \frac{B_{2k}}{2k} \frac{1}{N^{2k}},
\] (3.37)

where $B_m$ is the $m$-th Bernoulli number defined by the formula
\[
\frac{z}{e^z - 1} = \sum_{m=1}^{\infty} \frac{B_m}{m!} z^m.
\] (3.38)

Since $z(e^z-1)^{-1} + z/2$ is an even function of $z$, we have that $B_{2k+1} = 0$ for all $k \geq 1$.

Next, let us bound the integral $J_2(N; \theta)$ of (3.34). For any fixed $\rho > 0$ formula (3.34) implies
\[
J_2(N; \theta) \leq \int_0^{\rho N} (1 - e^{-(1-\theta)t/N})^N \, dt + \int_{\rho N}^{\infty} e^{-\theta t} \, dt \\
\leq \rho N (1 - e^{-(1-\theta)\rho})^N + \frac{1}{\theta \rho N} e^{-\theta \rho N}.
\] (3.39)

Hence, there is an $\varepsilon_1 > 0$ such that for any fixed $\varepsilon \in (0, \varepsilon_1)$ we have
\[
J_2(N; \theta) = O(e^{-\varepsilon N}), \quad N \to \infty
\] (3.40)
($\varepsilon$ is a symbol we recycle).

Using (3.36) and (3.40) in (3.32) yields
\[
E[S(\theta)] = \frac{NH_N}{1-\theta} + O(e^{-\varepsilon N}), \quad N \to \infty
\] (3.41)
(let us recall that in the case where all $N$ coupons are equally likely to occur we have $E[S_N] = NH_N$).

The full asymptotic expansion of $E[S(\theta)]$ can be obtained immediately by applying (3.37) in (3.41). In particular,
\[
E[S(\theta)] = \frac{N \ln N}{1-\theta} + \frac{\gamma N}{1-\theta} + O(1), \quad N \to \infty.
\] (3.42)

In the same way we can get the asymptotics of the second rising moment $E[S(\theta)^{(2)}]$ of $S(\theta)$. By (3.12) and (3.31) we get
\[
E[S(\theta)^{(2)}] = \tilde{J}_1(N; \theta) + \tilde{J}_2(N; \theta),
\] (3.43)

where
\[
\tilde{J}_1(N; \theta) := 2 \int_0^{\infty} t [1 - (1 - e^{-(1-\theta)t/N})^N] \, dt
\] (3.44)
and
\[
\tilde{J}_2(N;\theta) := 2 \int_0^\infty te^{-\theta t}(1 - e^{-(1-\theta)t/N})^Ndt.
\] (3.45)

The approach we used to bound \(J_2(N;\theta)\) applies to \(\tilde{J}_2(N;\theta)\) as well and it implies that there is an \(\varepsilon_2 > 0\) such that for any fixed \(\varepsilon \in (0,\varepsilon_2)\) we have
\[
\tilde{J}_2(N;\theta) = O(e^{-\varepsilon N}), \quad N \to \infty.
\] (3.46)

To calculate \(\tilde{J}_1(N;\theta)\) we substitute \(s = (1 - \theta)t\) in the integral of (3.44) and obtain
\[
\tilde{J}_1(N;\theta) = \frac{2}{(1 - \theta)^2} \int_0^\infty s[1 - (1 - e^{-s/N})^N]ds.
\] (3.47)

The integral in the right-hand side of (3.47) equals \(E[S_N^{(2)}]\), where \(S_N\) is the number of trials needed to collect all coupons in the uniform case where all \(N\) coupons are equally likely to occur. Since \(r = 2\) is a very special value, we can get more precise results than the ones coming directly from formula (3.25). Indeed, it is not hard to show (see, e.g., [3]) that
\[
E[S_N^{(2)}] = N^2 \left(H_N^2 + \sum_{j=1}^N \frac{1}{j^2}\right).
\] (3.48)

Therefore, (3.47) becomes
\[
\tilde{J}_1(N;\theta) = \frac{N^2}{(1 - \theta)^2} \left(H_N^2 + \sum_{j=1}^N \frac{1}{j^2}\right).
\] (3.49)

Using (3.46) and (3.49) in (3.43) we finally get
\[
E[S(\theta)^{(2)}] = \frac{N^2}{(1 - \theta)^2} \left(H_N^2 + \sum_{j=1}^N \frac{1}{j^2}\right) + O(e^{-\varepsilon N}), \quad N \to \infty,
\] (3.50)

for sufficiently small \(\varepsilon > 0\). The full asymptotic behavior of \(\sum_{j=1}^N j^{-2}\) is well known (see, e.g., [1])
\[
\sum_{j=1}^N \frac{1}{j^2} \sim \frac{\pi^2}{6} - \frac{1}{N} + \frac{1}{2N^2} - \sum_{k=1}^{\infty} \frac{B_{2k}}{N^{2k+1}},
\] (3.51)

hence we can obtain easily the full asymptotic expansion of \(E[S(\theta)^{(2)}]\) by using (3.37) and (3.51) in (3.50).

For the variance of \(S(\theta)\) we have
\[
V[S(\theta)] = E[S(\theta)^{(2)}] - E[S(\theta)]^2 - E[S(\theta)]^2,
\] (3.52)

hence applying (3.41) and (3.50) in (3.52) yields
\[
V[S(\theta)] = \frac{N^2}{(1 - \theta)^2} \sum_{j=1}^N \frac{1}{j^2} - \frac{NH_N}{1 - \theta} + O(e^{-\varepsilon N}), \quad N \to \infty,
\] (3.53)

for \(\varepsilon > 0\) sufficiently small. Again, the full asymptotic expansion of \(V[S(\theta)]\) can be obtained immediately with the help of (3.37) and (3.51). In particular,
\[
V[S(\theta)] = \frac{\pi^2N^2}{6(1 - \theta)^2} \left[1 + O\left(\frac{\ln N}{N}\right)\right], \quad N \to \infty.
\] (3.54)
In a similar fashion, we can compute the asymptotics of the fractional rising moments of $S(\theta)$. For $r > 0$, in view of (3.31), formula (3.10) becomes
\[
E[S(\theta)^{(r)}] = r \int_0^\infty t^{r-1} [1 - (1 - e^{-\theta t})(1 - e^{-(1-\theta)t/N})^N] dt
\]
\[
= r \int_0^\infty t^{r-1} [1 - (1 - e^{-(1-\theta)t/N})^N] dt + r \int_0^\infty t^{r-1} e^{-\theta t}(1 - e^{-(1-\theta)t/N})^N dt,
\]
(3.55)
thus, in the same way we got (3.40), we can now get
\[
E[S(\theta)^{(r)}] = r \int_0^\infty t^{r-1} [1 - (1 - e^{-(1-\theta)t/N})^N] dt + O(e^{-\varepsilon N}), \quad N \to \infty,
\]
(3.56)
for $\varepsilon > 0$ sufficiently small. Next, as usual, we substitute $s = (1 - \theta)t$ in the integral of (3.56) and obtain as $N \to \infty$
\[
E[S(\theta)^{(r)}] = \frac{1}{(1 - \theta)^r} \int_0^\infty r s^{r-1} [1 - (1 - e^{-s/N})^N] ds + O(e^{-\varepsilon N}).
\]
(3.57)
In view of (3.17), the integral in the right-hand side of (3.57) equals $E[S_N^{(r)}]$, where $S_N$ is the number of trials needed to collect all coupons in the uniform case. Hence, we can use formula (3.25) in (3.57) and conclude that
\[
E[S(\theta)^{(r)}] \sim \frac{N^r (\ln N)^r}{(1 - \theta)^r} \sum_{k=0}^\infty \binom{r}{k} \frac{(-1)^k \Gamma(k + 1)}{\ln^k N}, \quad N \to \infty,
\]
(3.58)
for any $r > 0$. In particular,
\[
E[S(\theta)^{(r)}] \sim \frac{N^r (\ln N)^r}{(1 - \theta)^r}, \quad N \to \infty.
\]
(3.59)
Furthermore, since $S(\theta) \geq N + 1$, in the same way we obtained (3.30), we can now get
\[
E[S(\theta)^{\ast}] \sim \frac{N^r (\ln N)^r}{(1 - \theta)^r}, \quad N \to \infty,
\]
(3.60)
for any $r > 0$.

Finally, we will give the limiting distribution of $S(\theta)$ as $N \to \infty$. The formulas for the moments and the variance of $S(\theta)$ suggest that the law of the random variable $(1 - \theta)S(\theta)$ must be very close to the law of the random variable $(1 - \theta)S_N = \text{the number of trials needed to detect all } N \text{ coupons in the uniform case where all coupons are equally likely to occur.}$

The limiting distribution of $S_N$ as $N \to \infty$ has been found in 1961 by Erdős and Rényi [7]:
\[
\frac{S_N - N \ln N}{N} \xrightarrow{D} Y \quad \text{as } N \to \infty,
\]
(3.61)
(the symbol $\xrightarrow{D}$ denotes convergence in distribution) where
\[
F(y) = P\{Y \leq y\} = \exp(-e^{-y}), \quad y \in \mathbb{R},
\]
(3.62)
namely $Y$ is a standard Gumbel random variable. Therefore, it is not surprising that
\[
\frac{(1 - \theta)S(\theta) - N \ln N}{N} \xrightarrow{D} Y \quad \text{as } N \to \infty,
\]
(3.63)
where, again, $Y$ is a standard Gumbel random variable.

Our proof of formula (3.63) is based on characteristic functions. The details are given in the Subsection 5.4 of Appendix.
4 The Asymptotic Behavior of $T_1$, $T_2$, and $T$

In this section we take advantage of the results presented in Section 3 in order to obtain the main results of the paper, which we have already mentioned in Subsection 1.1.

4.1 The Random Variables $T_1$ and $T_2$

If we are only interested in the variable $T_1 = T_1(M)$ alone, namely the number of trials needed to collect all $M_1 = \nu_1 M$ coupons of Group 1, then all the coupons of Group 2 feel the same to us, and consequently we can assume that Group 2 consists of only one coupon having probability $M_2 p_2 = \alpha_2$ to occur (recall (1.17)). Under this point of view, the number of trials $S = S_{M_1 + 1}$ needed to detect the totality of the $M_1 + 1$ existing coupons (i.e., the $M_1$ coupons of Group 1 plus the single coupon of Group 2) can be identified with the variable $S(\theta) = S(\theta; N)$ studied in Subsection 3.1, where $\theta = \alpha_2$ and $N = M_1 = \nu_1 M$. Although in our notation we will usually suppress the dependence on $M$ for typographical convenience, we should always keep in mind that both $T_1$ and $S$ below depend on the integer $M$.

Obviously, $T_1 \leq S$ and the event $\{T_1 < S\}$ happens if and only if Group 2 coupon occurs last, namely after detecting all $\nu_1 M$ Group 1 coupons. Therefore,

$$P\{T_1 < S\} \leq P\{\nu_1 M < S\} = (1 - \alpha_2)^{\nu_1 M} = \alpha_1^{\nu_1 M} \tag{4.1}$$

(the last equality follows from the fact that, in view of (1.17), $\alpha_1 + \alpha_2 = 1$). This is a rather crude estimate of the probability of $\{T_1 < S\}$, but it will be sufficient for our purpose.

Next, we will estimate the difference $S - T_1$ in the $L_1$ sense. Let us first notice that,

$$S - T_1 = (S - T_1) 1_{\{T_1 < S\}}. \tag{4.2}$$

Then, taking expectations in (4.2) yields

$$E[S - T_1] = E[(S - T_1) 1_{\{T_1 < S\}}] = E[S - T_1|T_1 < S]P\{T_1 < S\}. \tag{4.3}$$

Now, notice that for $k = 1, 2, \ldots, \nu_1 M$, we have $P\{S - T_1 = k|T_1 < S\} = \alpha_1^{k-1} \alpha_2$. Thus, the conditional distribution of $S - T_1$, given $\{T_1 < S\}$, is geometric with parameter $\alpha_2$. Therefore,

$$E[S - T_1|T_1 < S] = 1/\alpha_2$$

and (4.3) becomes

$$E[S] - E[T_1] = \frac{1}{\alpha_2} P\{T_1 < S\}. \tag{4.4}$$

which, in view of (4.1), implies that $S$ and $T_1$ get very close in the $L_1$ sense as $M \to \infty$. As for the asymptotics of $E[T_1]$, we can use (3.41) (with $\theta = \alpha_2$ and $N = \nu_1 M$) and (4.1) in (4.4) and obtain immediately the following result:

**Theorem 4.1** For every sufficiently small $\varepsilon > 0$, we have

$$E[T_1] = \frac{\nu_1}{\alpha_1} MH_{\nu_1 M} + O(e^{-\varepsilon M}) = (\nu_1 + \lambda \nu_2) MH_{\nu_1 M} + O(e^{-\varepsilon M}), \quad M \to \infty, \tag{4.5}$$

where $H_N$ is the $N$-th harmonic number (see (3.36)).

Likewise,

$$E[T_2] = \frac{\nu_2}{\alpha_2} MH_{\nu_2 M} + O(e^{-\varepsilon M}) = (\lambda^{-1} \nu_1 + \nu_2) MH_{\nu_2 M} + O(e^{-\varepsilon M}), \quad M \to \infty. \tag{4.6}$$

For example, in view of (3.37), formula (4.5) implies

$$E[T_1] = (\nu_1 + \lambda \nu_2) M \ln M + (\nu_1 + \lambda \nu_2)(\gamma + \ln \nu_1) M + \frac{\alpha_1}{2} + O\left(\frac{1}{M}\right), \quad M \to \infty, \tag{4.7}$$
where, recalling (1.17), we have that \( \alpha_1 = \nu_1/(\nu_1 + \nu_2) \).

We continue by noticing that in a similar way we can also get easily the asymptotics of the second rising moment of \( T_1 \). With the help of Schwarz’s inequality (and the fact that \( S \geq T_1 \)) we have

\[
E[S^2] - E[T_1^2] = E[S^2 - T_1^2] = E[(S + T_1)(S - T_1)] \\
\leq E[(S + T_1)^2]^{1/2} E[(S - T_1)^2]^{1/2} \\
\leq 2E[S^2]^{1/2} E[(S - T_1)^2]^{1/2}.
\]

(4.8)

Now, (4.2) implies that

\[
(S - T_1)^2 = (S - T_1)^2 \mathbf{1}_{\{T_1 < S\}}
\]

and hence, in the spirit of (4.3) and (4.4) we can get

\[
E[(S - T_1)^2] = E[(S - T_1)^2 \mid T_1 < S] P\{T_1 < S\} = \frac{1 + \alpha_1}{\alpha_2^2} P\{T_1 < S\}.
\]

Using (4.10) in (4.8) yields

\[
E[S^2] - E[T_1^2] \leq \frac{2\sqrt{1 + \alpha_1}}{\alpha_2} E[S^2]^{1/2} P\{T_1 < S\}^{1/2}.
\]

(4.11)

Thus, by (3.50) (with \( \theta = \alpha_2 \) and \( N = \nu_1 M \)) and (4.1) we get that the quantity in the left-hand side of (4.11) satisfies

\[
E[S^2] - E[T_1^2] = O(e^{-\varepsilon M}), \quad M \to \infty,
\]

(4.12)

for \( \varepsilon > 0 \) sufficiently small.

Therefore, by applying (3.50) (with \( \theta = \alpha_2 \) and \( N = \nu_1 M \)) in (4.12) together with Theorem 4.1 and (3.41) (with \( \theta = \alpha_2 \) and \( N = \nu_1 M \)) we obtain the following result:

**Theorem 4.2** For every sufficiently small \( \varepsilon > 0 \), we have

\[
E[T_1(T_1 + 1)] = \left( \frac{\nu_1}{\alpha_1} \right)^2 M^2 \left( H_{\nu_1 M}^2 + \sum_{j=1}^{\nu_1 M} \frac{1}{j^2} \right) + O(e^{-\varepsilon M})
\]

(4.13)

as \( M \to \infty \). Likewise,

\[
E[T_2(T_2 + 1)] = \left( \frac{\nu_2}{\alpha_2} \right)^2 M^2 \left( H_{\nu_2 M}^2 + \sum_{j=1}^{\nu_2 M} \frac{1}{j^2} \right) + O(e^{-\varepsilon M})
\]

(4.14)

as \( M \to \infty \).

From Theorems 4.1 and 4.2 we get immediately the following

**Corollary 4.3** For every sufficiently small \( \varepsilon > 0 \), we have

\[
V[T_1] = \left( \frac{\nu_1}{\alpha_1} \right)^2 \left( \sum_{j=1}^{\nu_1 M} \frac{1}{j^2} \right) M^2 - \frac{\nu_1}{\alpha_1} M H_{\nu_1 M} + O(e^{-\varepsilon M})
\]
\begin{align}
&= (\nu_1 + \lambda \nu_2)^2 \left( \sum_{j=1}^{M} \frac{1}{j^2} \right) M^2 - (\nu_1 + \lambda \nu_2) M H_{\nu_1, M} + O(e^{-\epsilon M}) \quad (4.15)
\end{align}
as \(M \to \infty\). Likewise,
\begin{align}
V[T_2] &= \left( \frac{\nu_2}{\alpha_2} \right)^2 \left( \sum_{j=1}^{M} \frac{1}{j^2} \right) M^2 - \frac{\nu_2}{\alpha_2} M H_{\nu_2, M} + O(e^{-\epsilon M}) \\
&= (\lambda^{-1} \nu_1 + \nu_2)^2 \left( \sum_{j=1}^{M} \frac{1}{j^2} \right) M^2 - (\lambda^{-1} \nu_1 + \nu_2) M H_{\nu_2, M} + O(e^{-\epsilon M}) \quad (4.16)
\end{align}
as \(M \to \infty\). In particular,
\begin{align}
V[T_1] &= \frac{\pi^2 (\nu_1 + \lambda \nu_2)^2}{6} M^2 \left[ 1 + O\left( \frac{\ln M}{M} \right) \right], \quad M \to \infty. \quad (4.17)
\end{align}

Let us, also, mention that a similar approach can be used to determine the asymptotics of \(E[T_1^{(r)}]\) and \(E[T_1^r]\). Indeed, formulas (3.59) and (3.60) (for \(\theta = \alpha_2\) and \(N = \nu_1 M\), as usual) imply
\begin{align}
E[T_1] \sim E[T_1^{(r)}] \sim E[S^{(r)}] \sim (\nu_1 + \lambda \nu_2)^r M^r (\ln M)^r, \quad M \to \infty, \quad r > 0. \quad (4.18)
\end{align}

Likewise,
\begin{align}
E[T_2] \sim E[T_2^{(r)}] \sim (\lambda^{-1} \nu_1 + \nu_2)^r M^r (\ln M)^r, \quad M \to \infty, \quad r > 0. \quad (4.19)
\end{align}

Finally, for \(\theta = \alpha_2\) and \(N = \nu_1 M\) formula (3.63) becomes
\begin{align}
\frac{S - (\nu_1 + \lambda \nu_2) M (\ln M + \ln \nu_1)}{(\nu_1 + \lambda \nu_2) M} \xrightarrow{D} Y \quad \text{as} \quad M \to \infty \quad (4.20)
\end{align}
where \(Y\) follows the standard Gumbel distribution displayed in (3.62). We can rewrite (4.20) as
\begin{align}
\frac{T_1 - (\nu_1 + \lambda \nu_2) M (\ln M + \ln \nu_1)}{(\nu_1 + \lambda \nu_2) M} + \frac{S - T_1}{(\nu_1 + \lambda \nu_2) M} \xrightarrow{D} Y \quad \text{as} \quad M \to \infty. \quad (4.21)
\end{align}

However, from (4.1) and (4.4) we have that \(S - T_1 \to 0\) in \(L_1\) and, therefore in probability (actually it is easy to see by using (4.1) and (4.4) and Chebyshev’s inequality that, for any \(\delta > 0\) we have \(\sum_{M=1}^{\infty} P\{S - T_1 > \delta\} < \infty\), hence \(P\{S - T_1 > \delta \text{ i.o.}\} = 0\) and the convergence is almost surely). It follows that \(S - T_1 \to 0\) in distribution as \(M \to \infty\). Therefore,
\begin{align}
\frac{S - T_1}{(\nu_1 + \lambda \nu_2) M} \xrightarrow{D} 0 \quad \text{as} \quad M \to \infty, \quad (4.22)
\end{align}
hence by combining (4.21) and (4.22) we obtain the following theorem regarding the limiting distribution of \(T_1\) (and \(T_2\)):

**Theorem 4.4**

\begin{align}
\frac{T_1 - (\nu_1 + \lambda \nu_2) M \ln M}{(\nu_1 + \lambda \nu_2) M} - \ln \nu_1 \xrightarrow{D} Y \quad \text{as} \quad M \to \infty \quad (4.23)
\end{align}

where
\begin{align}
F(y) = P\{Y \leq y\} = \exp(-e^{-y}), \quad y \in \mathbb{R}. \quad (4.24)
\end{align}

namely \(Y\) is a standard Gumbel random variable.

Likewise,
\begin{align}
\frac{T_2 - (\lambda^{-1} \nu_1 + \nu_2) M \ln M}{(\lambda^{-1} \nu_1 + \nu_2) M} - \ln \nu_2 \xrightarrow{D} Y \quad \text{as} \quad M \to \infty. \quad (4.25)
\end{align}
4.2 The Random Variable $T$

We are now ready to determine the asymptotic behavior of the variable $T = T_1 \vee T_2$ as $M \to \infty$. Without loss of generality, as in Section 2, we will assume for convenience that

$$\lambda = \frac{p_2}{p_1} > 1. \quad (4.26)$$

Let us first observe that we can write

$$T - T_1 = T_1 \vee T_2 - T_1 = (T_2 - T_1)1_{T_1 < T_2}. \quad (4.27)$$

Taking expectations in (4.27) yields

$$E[T - T_1] = E[(T_2 - T_1)1_{T_1 < T_2}] = E[T_2 - T_1 | T_1 < T_2]P\{T_1 < T_2\}. \quad (4.28)$$

From the fact that $T_1$ and $T_2$ are stopping times of the coupon filtration (recall (1.3)) we get

$$E[T_2 - T_1 | T_1 < T_2] \leq E[T_2], \quad (4.29)$$

thus, using (4.29) in (4.28) gives

$$E[T] - E[T_1] = E[T - T_1] \leq E[T_2]P\{T_1 < T_2\}. \quad (4.30)$$

Therefore, by invoking Theorems 2.1 and 4.1 we obtain

**Theorem 4.5**

$$E[T] = (\nu_1 + \lambda \nu_2)MH_{\nu_1 M} + O(M^{2-\lambda} \ln M), \quad M \to \infty, \quad (4.31)$$

where, as usual, $H_N$ denotes the $N$-th harmonic number.

Since $\lambda > 1$, formula (4.31) together with (3.37) implies

$$E[T] = (\nu_1 + \lambda \nu_2)M \ln M + (\nu_1 + \lambda \nu_2)(\gamma + \ln \nu_1)M + O(M^{2-\lambda} \ln M), \quad M \to \infty. \quad (4.32)$$

From Theorem 4.5 we see that the larger the $\lambda$ is, the more accurate the asymptotic formula for $E[T]$ becomes. The value $\lambda = 2$ is somehow critical, since if $\lambda > 2$, then (4.31) yields

$$E[T] = (\nu_1 + \lambda \nu_2)M \ln M + (\nu_1 + \lambda \nu_2)(\gamma + \ln \nu_1)M + \frac{\nu_1 + \lambda \nu_2}{2\nu_1} + o(1) \quad (4.33)$$

as $M \to \infty$.

We continue with the asymptotics of the second rising moment of $T$. We will follow the approach used in the previous subsection for $E[T_1^{(2)}]$. For better estimates, instead of the Schwarz’s inequality we use here the more general Hölder inequality (and the fact that $T \leq T_1 + T_2$) to get

$$E[T^2] - E[T_1^{(2)}] = E[T^2 - T_1^2]$$

$$= E[(T + T_1)(T - T_1)]$$

$$\leq E[(2T_1 + T_2)^r]^\frac{1}{r} E[(T - T_1)^s]^\frac{1}{s}, \quad (4.34)$$

where

$$r > 1 \quad \text{and} \quad s = \frac{r}{r - 1}. \quad (4.35)$$

An immediate upper bound of the first factor of the right-hand side of the inequality in (4.34) is given by the Minkowski inequality:

$$E[(2T_1 + T_2)^r]^\frac{1}{r} \leq 2E[T_1^{(r)}]^\frac{1}{r} + E[T_2^{(r)}]^\frac{1}{r}. \quad (4.36)$$
Now, (4.27) implies
\[(T - T_1)^s = (T - T_1)^s \mathbf{1}_{\{T_1 < T_2}\}} \quad (4.37)\]
and hence, in the spirit of (4.29)
\[E[(T - T_1)^s] = E[(T_2 - T_1)^s | T_1 < T_2]P\{T_1 < T_2\} \leq E[T_2^s]P\{T_1 < T_2\}. \quad (4.38)\]
Using (4.36) and (4.38) in (4.34) yields
\[E[T^2] - E[T_1^2] \leq (2E[T_1^2]^{\frac{1}{s}} + E[T_2^2]^{\frac{1}{s}})E[T_2^s]P\{T_1 < T_2\}^{\frac{1}{s}}. \quad (4.39)\]
Thus, by using (4.18), (4.19), and the result of Theorem 2.1 in (4.39) we obtain
\[E[T^2] - E[T_1^2] = O(M^{2-\frac{3}{s}} \ln^2 M), \quad M \to \infty. \quad (4.40)\]
If we had used the Schwarz’s inequality, then we would have been forced to take \(r = s = 2\). By using Hölder inequality, we are free to choose \(r\) as large as we wish and, consequently, in view of (4.35), we can take \(s\) arbitrarily close to 1. Thus, formula (4.40) is valid for any \(s > 1\) and we can write it as
\[E[T^2] = E[T_1^2] + O(M^{3-\lambda+\varepsilon}), \quad M \to \infty, \quad (4.41)\]
for any \(\varepsilon > 0\). Hence, by Theorems 4.1 and 4.5 formula (4.41) becomes
\[E[T^{(2)}] = E[T_1^{(2)}] + O(M^{3-\lambda+\varepsilon}), \quad M \to \infty. \quad (4.42)\]
Therefore, by using Theorem 4.2 in (4.42) we obtain the following result:

**Theorem 4.6** For every \(\varepsilon > 0\) we have
\[E[T^{(2)}] = (\nu_1 + \lambda \nu_2)^2 M^2 \left( R_{\nu_1 M}^3 + \sum_{j=1}^{\nu_1 M} \frac{1}{\nu_1^2} \right) + O(M^{3-\lambda+\varepsilon}), \quad M \to \infty. \quad (4.43)\]

Notice that, since \(\lambda > 1\) and \(\varepsilon\) can be taken arbitrarily close to 0, the exponent \(3 - \lambda + \varepsilon\) in the error term can be always assumed to be less than 2 (hence formula (4.42) is meaningful for any \(\lambda > 1\)). In particular, from (4.43) we can immediately deduce that
\[E[T^2] \sim E[T^{(2)}] \sim (\nu_1 + \lambda \nu_2)^2 M^2 \ln^2 M, \quad M \to \infty \quad (4.44)\]
and, furthermore, in a similar manner we can show that for any \(r > 0\) we have
\[E[T^r] \sim E[T^{(r)}] \sim (\nu_1 + \lambda \nu_2)^r M^r \ln^r M, \quad M \to \infty. \quad (4.45)\]

From Theorems 4.6 and 4.5 we get the following corollary.

**Corollary 4.7**
\[V[T] \sim \frac{\pi^2 (\nu_1 + \lambda \nu_2)^2}{6} M^2, \quad M \to \infty. \quad (4.46)\]

Finally, let us determine the limiting distribution of \(T\) as \(M \to \infty\). Formula (4.23) can be written as
\[\frac{T - (\nu_1 + \lambda \nu_2) M \ln M}{(\nu_1 + \lambda \nu_2) M} - \ln \nu_1 \sim \frac{T - T_1}{(\nu_1 + \lambda \nu_2) M} \overset{D}{\to} Y, \quad M \to \infty, \quad (4.47)\]
where \(Y\) is a standard Gumbel random variable. Moreover, by using (2.13) and (4.5) in (4.30) we get
\[E\left[ \frac{T - T_1}{(\nu_1 + \lambda \nu_2) M} \right] = O\left( \frac{\ln M}{M^{\lambda-1}} \right), \quad M \to \infty. \quad (4.48)\]
Since $\lambda > 1$, formula (4.48) implies that, as $M \to \infty$,
\[ \frac{T - T_1}{(\nu_1 + \nu_2)M} \to 0 \quad \text{in the } L_1 \text{ sense.} \quad (4.49) \]
Hence the above convergence is also in probability and, consequently, in distribution. Therefore, by using (4.49) in (4.47) we obtain immediately the limiting distribution of the random variable $T$ as $M \to \infty$:

**Theorem 4.8** Let $T$ be the number of trials required to detect all Group 1 and Group 2 coupons. Then,
\[ \frac{T - (\nu_1 + \nu_2)M \ln M}{(\nu_1 + \nu_2)M} - \ln \nu_1 \xrightarrow{D} Y \quad \text{as } M \to \infty, \]
where $Y$ is a standard Gumbel random variable.

4.3 Concluding Remarks
This work deals with a mixing problem involving a collection process. A collector samples coupons (with replacement) from a pool containing $g$ uniform groups of coupons. For each $j = 1, \ldots, g$, let $T_j$ be the number of trials needed to detect Group $j$, namely to collect all $M_j$ coupons belonging to it at least once. By applying the powerful technique of Poissonization we derive formulas for the probabilities $P\{T_1 < \cdots < T_g\}$ and $P\{T_1 = \bigwedge_{j=1}^g T_j\}$. After that, we restrict ourselves to the case $g = 2$ and compute the asymptotics of $P\{T_1 < T_2\}$ as the number of coupons grows to infinity in a certain manner (Section 2). Then, we focus on $T := T_1 \lor T_2$, i.e., the number of trials needed to collect all coupons of the pool (at least once), and determine the asymptotics of $E[T]$ and $V[T]$, as well as the limiting distribution of $T$ after the appropriate normalization, which turns out to be a Gumbel random variable (as the number of coupons becomes large, in Section 4). The main tools come from Section 3 (in particular Subsection 3.1), where a key example is considered. To give closure we mention that mixing problems are certainly of interest. Recently, the problem where the family of coupon probabilities is the mixing of two subfamilies one of which is the uniform family, while the other belongs to the so-called Zipf family has been considered, see [5].

Acknowledgements The authors wish to thank the anonymous referee for reading the manuscript very carefully and making several valuable comments and suggestions which improved significantly this work.

5.1 Proof of Theorem 1.1

Following a suggestion of Professor Sheldon M. Ross [8] we prove the formulas by applying the technique of “Poissonization”. Let $Z(t)$, $t \geq 0$, be a Poisson process with rate $\lambda = 1$. We imagine that each Poisson event associated to this process is a sampled coupon, so that $Z(t)$ is the number of sampled coupons at time $t$. Next, for $i = 1, \ldots, (M_1 + \cdots + M_g)$, let $Z_i(t)$ be the number of type-$i$ coupons collected at time $t$. Then, the processes $\{Z_i(t)\}_{t \geq 0}$, $i = 1, \ldots, (M_1 + \cdots + M_g)$, are independent Poisson processes with rates $p_i$ for $i = 1, \ldots, M_1$, $p_2$ for $i = (M_1 + 1), \ldots, (M_1 + M_2)$, and, finally, $p_g$ for $i = (M_1 + \cdots + M_{g-1} + 1), \ldots, (M_1 + \cdots + M_g)$ [9]. Of course, $Z(t) = Z_1(t) + \cdots + Z_{M_1+\cdots+M_g}(t)$.

If $X_i$, $i = 1, \ldots, (M_1 + \cdots + M_g)$, denotes the time when the first type-$i$ coupon is collected, i.e., the time of the first Poisson event of the process $Z_i(t)$, then the variables $X_1, \ldots, X_{M_1+\cdots+M_g}$ are clearly independent (being associated to independent processes) and exponentially distributed with parameters $p_i$ for $i = 1, \ldots, M_1$, $p_2$ for $i = (M_1 + 1), \ldots, (M_1 + M_2)$ and so on. We now set

$$T_1 := \bigvee_{i=1}^{M_1} X_i, \quad T_2 := \bigvee_{i=M_1+1}^{M_1+M_2} X_i, \quad \ldots, \quad T_g := \bigvee_{i=M_1+\cdots+M_{g-1}+1}^{M_1+\cdots+M_g} X_i. \quad (5.1)$$

Thus $T_j$, $j = 1, \ldots, g$, is the time when all Group $j$ coupons have been detected (at least once) by the process $Z(t)$ and, hence,

$$P\{T_1 < \cdots < T_g\} = P\{\bar{T}_1 < \cdots < \bar{T}_g\} \quad \text{and} \quad P\{T_1 = T_{\text{min}}\} = P\{\bar{T}_1 = \bar{T}_{\text{min}}\}, \quad (5.2)$$

where, of course, $T_{\text{min}} := \bigwedge_{j=1}^{g} T_j$.

From the independence of the exponential random variables $X_i$, $i = 1, \ldots, (M_1 + \cdots + M_g)$, it follows that the variables $\bar{T}_1, \bar{T}_2, \ldots, \bar{T}_g$ are also independent and, furthermore, (5.1) implies

$$F_j(t) := P\{\bar{T}_j \leq t\} = (1 - e^{-p_j t})^{M_j}, \quad t \geq 0, \quad j = 1, \ldots, g, \quad (5.3)$$

and

$$f_j(t) := F'_j(t) = p_j M_j e^{-p_j t} (1 - e^{-p_j t})^{M_j-1}, \quad t \geq 0, \quad j = 1, \ldots, g. \quad (5.4)$$

Therefore,

$$P\{\bar{T}_1 < \cdots < \bar{T}_g\} = \int_0^\infty \cdots \int_0^{t} \int_0^{t_2} f_g(t_g) \cdots f_2(t_2) f_1(t_1) \, dt_1 dt_2 \cdots dt_g$$

$$= \int_0^\infty \cdots \int_0^{t_2} f_g(t_g) \cdots f_2(t_2) f_1(t_1) \, dt_2 \cdots dt_g$$

and, in view of (5.2), (5.3), (5.4), and (1.6) the above formula is equivalent to (1.5). Likewise,

$$P\{\bar{T}_1 = \bar{T}_{\text{min}}\} = \int_0^\infty \cdots \int_0^{t_2 \wedge \cdots \wedge t_g} f_g(t_g) \cdots f_2(t_2) f_1(t_1) \, dt_1 dt_2 \cdots dt_g$$
or, equivalently,

\[ \int_0^\infty \cdots \int_0^\infty f_g(t_g) \cdots f_2(t_2) F_1(t_2 \wedge \cdots \wedge t_g) \, dt_2 \cdots dt_g, \]

which establishes (1.7).

5.2 Proof of Corollary 1.2

It is enough to prove (1.8) only for the case \( \ell = 1 \). For \( j = 2, \ldots, g \) we have

\[ p_j M_j e^{-p_j t_j} (1 - e^{-p_j t_j})^{M_j - 1} = - \sum_{k_j = 1}^{M_j} (-1)^{k_j} \left( \frac{M_j}{k_j} \right) p_j k_j e^{-k_j p_j t_j}, \]

(5.5)

while

\[ [1 - e^{-p_1 (t_2 \wedge \cdots \wedge t_g)}] M_1 = \sum_{k_1 = 0}^{M_1} (-1)^{k_1} \left( \frac{M_1}{k_1} \right) e^{-k_1 p_1 (t_2 \wedge \cdots \wedge t_g)}. \]

(5.6)

Substituting (5.5), (5.6), and (1.6) in (1.7) yields

\[ P\{T_1 = T_{\min}\} = (-1)^{g-1} \sum_{k_g = 1}^{M_g} \cdots \sum_{k_2 = 1}^{M_2} \sum_{k_1 = 0}^{M_1} (-1)^{k_1 + \cdots + k_g} \left( \frac{M_g}{k_g} \right) \cdots \left( \frac{M_1}{k_1} \right) I, \]

(5.7)

where

\[ I := \int_0^\infty \cdots \int_0^\infty k_g p_g \cdots k_2 p_2 e^{-\left( k_g p_g t_g + \cdots + k_2 p_2 t_2 \right)} e^{-k_1 p_1 (t_2 \wedge \cdots \wedge t_g)} \, dt_2 \cdots dt_g. \]

(5.8)

A quick look at (5.8) reveals that

\[ I = E[e^{-k_1 p_1 Y_{\min}}], \]

(5.9)

where \( Y_{\min} \) is the minimum of the independent exponential random variables \( Y_2, \ldots, Y_g \) with parameters \( (k_2 p_2), \ldots, (k_g p_g) \) respectively. Since (as it is well known) \( Y_{\min} \) is exponentially distributed with parameter \( k_2 p_2 + \cdots + k_g p_g \), it follows from (5.9) that

\[ I = \frac{k_2 p_2 + \cdots + k_g p_g}{k_1 p_1 + (k_2 p_2 + \cdots + k_g p_g)} \]

(5.10)

and the substitution of (5.10) in (5.7) gives

\[ P\{T_1 = T_{\min}\} = (-1)^{g-1} \sum_{k_g = 1}^{M_g} \cdots \sum_{k_2 = 1}^{M_2} \sum_{k_1 = 0}^{M_1} (-1)^{k_1 + \cdots + k_g} \left( \frac{M_g}{k_g} \right) \cdots \left( \frac{M_1}{k_1} \right) \frac{k_2 p_2 + \cdots + k_g p_g}{k_1 p_1 + k_2 p_2 + \cdots + k_g p_g}, \]

(5.11)

or, equivalently,

\[ P\{T_1 = T_{\min}\} = (-1)^g \sum_{k_g = 1}^{M_g} \cdots \sum_{k_2 = 1}^{M_2} \sum_{k_1 = 0}^{M_1} (-1)^{k_1 + \cdots + k_g} \left( \frac{M_g}{k_g} \right) \cdots \left( \frac{M_1}{k_1} \right) \frac{k_1 p_1}{k_1 p_1 + k_2 p_2 + \cdots + k_g p_g} \\
- (-1)^g \sum_{k_g = 1}^{M_g} \cdots \sum_{k_2 = 1}^{M_2} \sum_{k_1 = 0}^{M_1} (-1)^{k_1 + \cdots + k_g} \left( \frac{M_g}{k_g} \right) \cdots \left( \frac{M_1}{k_1} \right). \]

(5.12)

In the first multiple sum of the right-hand side of (5.12), clearly, the value \( k_1 = 0 \) of the dummy variable \( k_1 \) can be omitted since it does not contribute anything to the sum. Hence we may as
We will first estimate $I$. In particular (5.17) implies

$$\sum_{k_g=1}^{M_g} (-1)^{k_g} \binom{M_g}{k_g} \cdots \sum_{k_2=1}^{M_2} (-1)^{k_2} \binom{M_2}{k_2} \cdots \sum_{k_1=0}^{M_1} (-1)^{k_1} \binom{M_1}{k_1},$$

where, obviously, the last factor is equal to 0 (being the binomial expansion of $(1 - 1)^{M_1}$). Hence the whole multiple sum vanishes, and (5.12) reduces to (1.8) (for $\ell = 1$).

Formulas (1.9) and (1.10) follow immediately from (1.8).

5.3 Proof of Formula (3.21)

Let $\alpha \in (0, 1)$. For typographical convenience we set

$$U(N; \alpha) := e^{\ln^\alpha N} \quad (5.13)$$

so that for any constant $\beta > 0$ we have $\ln^\beta N \ll U(N; \alpha) \ll N^\beta$ as $N \to \infty$) and then we write (3.20) as

$$E[S_N^{(\alpha)}] = N^\alpha \ln N[I_1(N) + I_2(N)], \quad (5.14)$$

where

$$I_1(N) := \int_0^{U(N; \alpha)} \left(1 - \frac{x}{N}\right)^{N-1} \left(1 - \frac{\ln x}{\ln N}\right)^r \, dx \quad (5.15)$$

and

$$I_2(N) := \int_{U(N; \alpha)}^{N} \left(1 - \frac{x}{N}\right)^{N-1} \left(1 - \frac{\ln x}{\ln N}\right)^r \, dx. \quad (5.16)$$

We will first estimate $I_2(N)$ as $N \to \infty$.

$$0 < I_2(N) \leq \left(1 - \frac{U(N; \alpha)}{N}\right)^{N-1} \int_{U(N; \alpha)}^{N} \left(1 - \frac{\ln x}{\ln N}\right)^r \, dx \leq N \left[\left(1 - \frac{U(N; \alpha)}{N}\right)^{\frac{N-1}{U(N; \alpha)}} \right] U(N; \alpha) \sim Ne^{-U(N; \alpha)}. \quad (5.17)$$

In particular (5.17) implies

$$I_2(N) = o\left(\frac{1}{N^\kappa}\right) \quad \text{for any } \kappa > 0. \quad (5.18)$$

To estimate $I_1(N)$ we first notice that for $0 \leq x \leq U(N; \alpha) = e^{\ln^\alpha N}$ we have

$$(N - 1) \ln \left(1 - \frac{x}{N}\right) = -(N - 1) \left[\frac{x}{N} + O\left(\frac{x^2}{N^2}\right)\right] = -x + o\left(\frac{1}{N^\theta}\right) \quad (5.19)$$

for any $\theta \in (0, 1)$. Exponentiating (5.19) yields

$$\left(1 - \frac{x}{N}\right)^{N-1} = e^{-x} \left[1 + o\left(\frac{1}{N^\theta}\right)\right] \quad \text{for any } \theta \in (0, 1). \quad (5.20)$$

We, then, substitute (5.20) in (5.15) and obtain

$$I_1(N) = \int_0^{U(N; \alpha)} e^{-x} \left(1 - \frac{\ln x}{\ln N}\right)^r \, dx + o\left(\frac{1}{N^\theta}\right) \int_0^{U(N; \alpha)} e^{-x} \left(1 - \frac{\ln x}{\ln N}\right)^r \, dx. \quad (5.21)$$
Now, 
\[ \int_{0}^{U(N;\alpha)} e^{-x} \left( 1 - \frac{\ln x}{\ln N} \right)^r \, dx \leq \int_{0}^{1} e^{-x} \left( 1 - \frac{\ln x}{\ln N} \right)^r \, dx + \int_{1}^{U(N;\alpha)} e^{-x} \, dx = O(1) \]  
(5.22)
as \( N \to \infty \). Thus, by using (5.22) in (5.21) we arrive at 
\[ I_1(N) = \int_{0}^{U(N;\alpha)} e^{-x} \left( 1 - \frac{\ln x}{\ln N} \right)^r \, dx + o\left( \frac{1}{N^{\theta}} \right) \quad \text{for any } \theta \in (0, 1). \]  
(5.23)
Since \( \ln x \to -\infty \) as \( x \to 0^+ \), we need to estimate the “bottom tail” of the integral in (5.23). We have 
\[ 0 < \int_{0}^{U(N;\alpha)^{-1}} e^{-x} \left( 1 - \frac{\ln x}{\ln N} \right)^r \, dx < \left( \frac{2r}{\ln N} + \frac{2r}{\ln^N N} \right) \int_{0}^{U(N;\alpha)^{-1}} (-\ln x)^r \, dx \]  
(5.24)
(recall that \( U(N;\alpha)^{-1} = e^{-\ln^N N} \), where \( 0 < \alpha < 1 \)). Integration by parts gives 
\[ \int_{0}^{U(N;\alpha)^{-1}} (-\ln x)^r \, dx = e^{-\ln^N N} (\ln N)^r \alpha [1 + o(1)], \]  
(5.25)
hence, by using (5.25) in (5.24) we obtain 
\[ \int_{0}^{U(N;\alpha)^{-1}} e^{-x} \left( 1 - \frac{\ln x}{\ln N} \right)^r \, dx = o(e^{-\ln^N N}). \]  
(5.26)
In view of (5.26), formula (5.23) implies 
\[ I_1(N) = \int_{U(N;\alpha)^{-1}}^{U(N;\alpha)} e^{-x} \left( 1 - \frac{\ln x}{\ln N} \right)^r \, dx + o(e^{-\ln^N N}). \]  
(5.27)
Finally, by substituting (5.18) and (5.27) in (5.14) we get 
\[ E[S_N^{(r)}] = N^r(\ln N)^r J(N;\alpha), \]  
(5.28)
where 
\[ J(N;\alpha) := \int_{U(N;\alpha)^{-1}}^{U(N;\alpha)} e^{-x} \left( 1 - \frac{\ln x}{\ln N} \right)^r \, dx + o(e^{-\ln^N N}) \]  
(5.29)
as \( N \to \infty \).
Before we continue we recall that, for any \( r > 0 \), the function 
\[ h(y) := (1 - y)^r \]  
has the Taylor series expansion 
\[ h(y) = (1 - y)^r = \sum_{k=0}^{\infty} (-1)^k \binom{r}{k} y^k, \quad y \in [-1, 1], \]  
(5.30)
where 
\[ \binom{r}{0} = 1 \quad \text{and} \quad \binom{r}{k} = \frac{r(r-1) \cdots (r-k+1)}{k!} \quad \text{for } k = 1, 2, \ldots. \]  
(5.31)
Thus, if \( n \geq 1 \) is a fixed integer, then 
\[ h(y) = (1 - y)^r = \sum_{k=0}^{n} (-1)^k \binom{r}{k} y^k + \frac{h^{(n+1)}(\xi)}{(n+1)!} y^{n+1}, \]  
(5.32)
where \( \xi \) lies between 0 and \( y \).
Going back to formula (5.29) we see that due to the limits of integration the dummy variable \( x \) satisfies

\[
-\frac{\ln^\alpha N}{\ln N} \leq \frac{\ln x}{\ln N} \leq \frac{\ln^\alpha N}{\ln N}.
\]

(5.33)

Hence, if we set \( y = \frac{\ln x}{\ln N} \) in (5.32), then the quantity \( \frac{h^{(\alpha+1)}(\xi)}{(\alpha+1)!} \) is bounded and we get

\[
\left(1 - \frac{\ln x}{\ln N}\right)^r = \sum_{k=0}^n (-1)^k \binom{r}{k} \left(\frac{\ln x}{\ln N}\right)^k + O\left(\frac{\ln^{\alpha(n+1)} N}{\ln^{n+1} N}\right)
\]

(5.34)

uniformly in \( x \), as long as the range of values of \( x \) is given by (5.33).

It follows from (5.34) that if (for our given \( n \)) we choose an \( \alpha \) so that

\[
0 < \alpha < \frac{1}{n+1},
\]

(5.35)

then

\[
\left(1 - \frac{\ln x}{\ln N}\right)^r = \sum_{k=0}^n (-1)^k \binom{r}{k} \left(\frac{\ln x}{\ln N}\right)^k + O\left(\frac{1}{\ln^n N}\right)
\]

(5.36)

again uniformly in \( x \), within the range of values given by (5.33). Thus, we can substitute (5.36) in (5.29) and get

\[
J(N;\alpha) = \sum_{k=0}^n \binom{r}{k} (-1)^k \frac{1}{\ln^k N} \int_{U(N;\alpha)^{-1}} e^{-x} (\ln x)^k dx + o\left(\frac{1}{\ln^n N}\right)
\]

(5.37)

as \( N \to \infty \).

Next, we observe that in the same way we derived (5.26) we can also get

\[
\int_0^{U(N;\alpha)^{-1}} e^{-x} (\ln x)^k dx = o(e^{-\ln^\alpha N} \ln^k N).
\]

(5.38)

Also, it is easy to see that

\[
\int_{U(N;\alpha)} e^{-x} (\ln x)^k dx = O(e^{-U(N;\alpha)} (\ln N)^\alpha k)
\]

(5.39)

(recall that \( U(N;\alpha) = e^{\ln^\alpha N} \)). Therefore, by using (5.38) and (5.39) in (5.37) we obtain

\[
J(N;\alpha) = \sum_{k=0}^n \binom{r}{k} (-1)^k \frac{1}{\ln^k N} \int_0^\infty e^{-x} (\ln x)^k dx + o\left(\frac{1}{\ln^n N}\right), \quad N \to \infty,
\]

(5.40)

and, finally, by substituting (5.40) in (5.28) we arrive at (3.21).

5.4 Proof of Formula (3.63)

We start by introducing the generating functions

\[
G(z) := E[z^{-S(\theta)}] = 1 - (z - 1) \int_0^\infty e^{-(z-1)t}[1 - (1 - e^{-\theta t})(1 - e^{-(1-\theta)t/N})] dt.
\]

(5.41)

Notice that if

\[
\Re\{z\} > 1 - \frac{\theta}{N},
\]

(5.42)

the integral appearing in (5.41) is absolutely convergent.
We will derive formula (3.63) via characteristic functions. Let us fix a $\xi \in \mathbb{R}$ and set
\[ \zeta := e^{-i\xi}. \] (5.43)
Then, in view of (5.41), the characteristic function of $[(1 - \theta)S(\theta) - N \ln N]/N$ is
\[ \phi_N(\xi) = E[\zeta^{-(1 - \theta)S(\theta) - N \ln N}] = \zeta^{N} E[(\zeta^{(1 - \theta)\theta})^{S(\theta)}] = \zeta^{N} G(\zeta^{(1 - \theta)\theta}). \] (5.44)
Now,
\[ \zeta^{(1 - \theta)\theta} = e^{-(1 - \theta)i\xi} = 1 - \frac{i(1 - \theta)\xi}{N} + O\left(\frac{1}{N^2}\right), \quad N \to \infty. \] (5.45)
In particular $z = \zeta^{(1 - \theta)\theta}/N$ satisfies (5.42) for all $N$ sufficiently large.

Next, by using (5.41) and (5.45) in (5.44) we get
\[ \zeta^{-\ln N} \phi_N(\xi) = 1 + \left[\frac{i(1 - \theta)\xi}{N} + O\left(\frac{1}{N^2}\right)\right] [\chi_1(N) + \chi_2(N)], \] (5.46)
where
\[ \chi_1(N) := \int_{0}^{\infty} e^{-(\zeta^{(1 - \theta)\theta} - 1)t}[1 - (1 - e^{-(1 - \theta)t/N})^N]dt \] (5.47)
and
\[ \chi_2(N) := \int_{0}^{\infty} e^{-(\zeta^{(1 - \theta)\theta} - 1)t}e^{-\theta t}(1 - e^{-(1 - \theta)t/N})^N dt. \] (5.48)
Regarding $\chi_2(N)$, in the same way we got formula (3.40) from (3.39) we can obtain
\[ \chi_2(N) = O(e^{-\varepsilon N}), \quad N \to \infty, \] (5.49)
for any sufficiently small $\varepsilon > 0$.

Now, using (5.45) in (5.47) yields
\[ \chi_1(N) = \int_{0}^{\infty} e^{[i(1 - \theta)\xi + O(N^{-1})]t/N}[1 - (1 - e^{-(1 - \theta)t/N})^N]dt \] (5.50)
or, after the substitution $s = (1 - \theta)t/N$ in the above integral
\[ \chi_1(N) = \frac{N}{1 - \theta} \int_{0}^{\infty} e^{i\xi s + O(N^{-1})}[1 - (1 - e^{-s})^N]ds. \] (5.51)
Therefore, by substituting (5.49) and (5.51) in (5.46) we obtain
\[ \zeta^{-\ln N} \phi_N(\xi) = 1 + \left[i\xi + O\left(\frac{1}{N}\right)\right] \int_{0}^{\infty} e^{i\xi s + O(N^{-1})}[1 - (1 - e^{-s})^N]ds \]
\[ = 1 + i\xi \int_{0}^{\infty} e^{i\xi s}[1 - (1 - e^{-s})^N]ds + O\left(\frac{1}{N}\right) \] (5.52)
as $N \to \infty$.

Let $A_N$ be a (real) quantity which grows to $\infty$ with $N$ so that
\[ \frac{N}{e^{A_N}} = o\left(\frac{1}{N}\right) \quad \text{as} \quad N \to \infty \] (5.53)
(we do not need to be more specific about $A_N$). Noticing that by (5.43) we have $\zeta^{-\ln N} = N^i\xi$, we rewrite (5.52) as
\[ N^i\xi \phi_N(\xi) = 1 + K_1(N) + K_2(N) + O\left(\frac{1}{N}\right), \] (5.54)
Doumas A. V. and Papanicolaou V. G.

where
\[ K_1(N) := \int_0^{A_N} i\xi e^{i\xi s}[1 - (1 - e^{-s})^N]ds \] (5.55)
and
\[ K_2(N) := \int_{A_N}^{\infty} i\xi e^{i\xi s}[1 - (1 - e^{-s})^N]ds. \] (5.56)

Applying integration by parts in (5.55) yields
\[ K_1(N) = e^{i\xi A_N}[1 + (1 - e^{-A_N})^N] - 1 + N \int_0^{A_N} e^{i\xi s}(1 - e^{-s})^{N-1}e^{-s}ds, \] (5.57)
which, in view of (5.53), implies
\[ K_1(N) = e^{i\xi A_N} - 1 + N \int_0^{A_N} e^{i\xi s}(1 - e^{-s})^{N-1}e^{-s}ds + o\left(\frac{1}{N}\right). \] (5.58)

Next, by substituting \( s = \ln N - \ln x \) in the integral appearing in the right-hand side of (5.58) we obtain
\[ K_1(N) = e^{i\xi A_N} - 1 + N^i\xi \int_{Ne^{-A_N}}^{N} x^{-i\xi} \left(1 - \frac{x}{N}\right)^{N-1} dx + o\left(\frac{1}{N}\right). \] (5.59)

We, then, use (5.59) in (5.54) and get
\[ N^i\xi \phi_N(\xi) = e^{iA_N}\xi + N^i\xi \int_{Ne^{-A_N}}^{N} x^{-i\xi} \left(1 - \frac{x}{N}\right)^{N-1} dx + K_2(N) + O\left(\frac{1}{N}\right). \] (5.60)

Let us, now, turn our attention to the integral \( K_2(N) \) of formula (5.56).

Assume first that \( \xi > 0 \). We complexify the dummy variable \( s \) by setting \( z = s + i\theta \) and for \( N \) (temporarily) fixed we choose \( R > A_N \) and consider the close contour \( C_R \) formed by (i) the interval \([A_N, R]\) of the (real) \( s \)-axis, (ii) the circular arc \( Re^{i\theta}, 0 \leq \theta \leq \arccos(A_N/R) \), and (iii) the line segment \( A_N + i\tau, 0 \leq \tau \leq \sqrt{R^2 - A_N^2} \). Then, Cauchy’s Theorem implies
\[ \oint_{C_R} i\xi e^{i\xi z}[1 - (1 - e^{-z})^N]dz = 0 \quad \text{for every } R > A_N. \] (5.61)

Next (keeping \( N \) fixed), we take limits in (5.61) as \( R \to \infty \). It is a standard exercise in contour integration to show that the integral on the circular piece of \( C_R \), namely on the arc \( Re^{i\theta}, 0 \leq \theta \leq \arccos(A_N/R) \), vanishes. Hence, in view of (5.56), formula (5.61) implies
\[ K_2(N) = -e^{i\xi A_N} \int_0^{\infty} \xi e^{-\xi\tau}[1 - (1 - e^{-A_N e^{-i\tau}})^N]d\tau. \] (5.62)

Now, we can allow \( N \) to grow large. Thus, in view of (5.53), formula (5.62) yields
\[ K_2(N) = -e^{i\xi A_N} + o\left(\frac{1}{N}\right) \] (5.63)
and, hence, by substituting (5.63) in (5.60) we obtain
\[ \phi_N(\xi) = \int_{Ne^{-A_N}}^{N} x^{-i\xi} \left(1 - \frac{x}{N}\right)^{N-1} dx + O\left(\frac{1}{N}\right). \] (5.64)

Formula (5.64) was obtained under the assumption that \( \xi > 0 \). However, if \( \xi < 0 \), then the same approach works if we choose the contour \( C_R \) to be the symmetric of the previous one with
respects to the (real) $s$-axis. Therefore, formula (5.64) is valid for all $\xi \in \mathbb{R} \setminus \{0\}$, while for $\xi = 0$ formulas (5.43) and (5.44) imply immediately that

$$\phi_N(0) = 1 \quad \text{for all } N. \quad (5.65)$$

Finally, as in the previous subsection (see, e.g., (5.15) and (5.20)), formulas (5.64) and (5.65) imply

$$\lim_{N \to \infty} \phi_N(\xi) = \int_0^\infty x^{-i\xi} e^{-x} \, dx = \Gamma(1 - i\xi) \quad \text{pointwise for } \xi \in \mathbb{R}, \quad (5.66)$$

where $\Gamma(1 - i\xi)$ is recognized as the characteristic function of the standard Gumbel distribution.
