(Dated: March 27, 2012)

We present a combination of local density approximation (LDA) with the dynamical cluster approximation (LDA+DCA) in the framework of the full-potential linear augmented plane-wave method, and compare our LDA+DCA results for SrVO$_3$ to LDA with the dynamical mean field theory (LDA+DMFT) calculations as well as experimental observations on SrVO$_3$. We find a qualitative agreement of the momentum resolved spectral function with angle-resolved photoemission spectra (ARPES) and former LDA+DMFT results. As a correction to LDA+DMFT, we observe more pronounced coherent peaks below the Fermi level, as indicated by ARPES experiments. In addition, we resolve the spectral functions in the $K_0 = (0,0,0)$ and $K_1 = (\pi,\pi,\pi)$ sectors of DCA, where band insulating and metallic phases coexist. Our approach can be applied to correlated compounds where not only local quantum fluctuations but also spatial fluctuations are important.

PACS numbers: 71.10.Fd

I. INTRODUCTION

The development of reliable numerical tools for the description of the electronic structure of correlated compounds is one of the most challenging tasks in the condensed matter community. As an example, transition-metal perovskites with partially filled d-electrons is one of the most challenging tasks in the description of the electronic structure of correlated compounds including long-range correlations have been developed by considering a perturbation expansion where nonlocal contributions are obtained from the two-particle vertex functions.$^{25–29}$

Recent progress towards a realistic description of correlated systems is the combination of LDA with DMFT$^{30}$ (LDA+DMFT). While this approach has proven to be quite successful for the description of spectral properties of transition metal oxides$^{31–38}$ and the newly discovered iron-based superconductors$^{39–41}$, effects originating from spatial fluctuations remain inconclusive. Attempts to include short-range spatial fluctuations have been done in the context of the spin-Peierls system TiOCl -where pairing correlations are important- within an N$^\text{th}$ order muffin tin orbital (NMTO) approach combined with DCA$^{42}$ as well as NMTO combined with a variational cluster approach (VCA)$^{43}$. In this work, we present an alternative approach where we extend a newly developed implementation of the LDA+DMFT approach$^{21}$ in the context of the full-potential linearized augmented plane wave (FLAPW)$^{44}$ method by including spatial fluctuations within DCA (LDA+DCA), and we investigate the spectral properties of SrVO$_3$ as a test case.

The paper is organized as follows: in section II, we describe our LDA+DCA implementation with a weak-coupling continuous-time quantum Monte Carlo (CT-QMC) algorithm$^{45–47}$ for multi-orbital systems with multiple sites. In section III, we present results for SrVO$_3$ within LDA+DCA with a cluster of two sites and compare them with single-site LDA+DMFT calculations as well as experimental observations and in section IV we summarize our findings.
II. THEORETICAL FRAMEWORK

A. LDA+DCA in the APW framework

In this work, we extend a recent implementation of LDA+DMFT\(^{14}\) to LDA+DCA which includes short-range spatial correlations. We first shortly review the projection operators within the WIEN2K code\(^{32}\). The local atomic-like Wannier orbital functions inside an appropriate energy window \(W\) can be expanded over the Bloch basis set as

\[
|\chi_{k,m}^{\alpha,\sigma}\rangle = \sum_{\nu \in W} \langle \psi_{k,\nu}^{\sigma} | \chi_{m}^{\alpha,\sigma}\rangle |\psi_{k,\nu}\rangle,
\]

where \(\alpha\) indicates the correlated atom, \(\nu\) is the band index, \(\sigma\) the spin index, and \(m\) the orbital index. Here, \(|\psi_{k,\nu}\rangle\) is the Bloch eigenfunction in the augmented plane wave basis and the correlated orbital \(|\chi_{m}^{\alpha,\sigma}\rangle\) is given as \(|\chi_{m}^{\alpha,\sigma}\rangle = |u_{m,\sigma}^{\alpha,\sigma} (E_{l}) Y_{l}^{\mu}\rangle\) within the muffin tin sphere, where \(E_{l}\) are chosen linearization energies, \(u_{m,\sigma}^{\alpha,\sigma}\) is the radial wave function, and \(Y_{l}^{\mu}\) is the spherical harmonic function. The orthonormalized projector operators for the DMFT and DCA self-consistent equations are calculated by

\[
P_{m,\nu}^{\alpha,\sigma}(k) = \sum_{\alpha',m'} \langle u_{m',\sigma}^{\alpha',\sigma} (E_{l}) Y_{m'}^{l} | \psi_{k,\nu}^{\sigma}\rangle |\psi_{k,\nu}\rangle \overline{O(k,\sigma)}^{-1/2} \overline{f_{m,m'}}_{l,m',\nu},
\]

where \(O(k,\sigma)_{m,m'}^{\alpha,\alpha'}\) is the overlap function which is given as

\[
O(k,\sigma)_{m,m'}^{\alpha,\alpha'} = \sum_{\nu \in W} \langle \chi_{m}^{\alpha,\sigma} | \psi_{k,\nu}^{\sigma}\rangle \langle \psi_{k,\nu}^{\sigma}| \chi_{m'}^{\alpha',\sigma}\rangle.
\]

For the LDA+DCA self-consistency procedure, the lattice Green’s function is given as

\[
G_{\nu,\nu'}^{\sigma}(k+\tilde{k},\omega_{n}) = \frac{1}{i\omega_{n} + \mu - \epsilon_{k+\tilde{k},\nu}^{\sigma} - \Delta_{\nu,\nu'}^{\sigma}(k+\tilde{k},\omega_{n})},
\]

where we have defined \(k = K + \tilde{k}\) with \(K\) being the cluster momenta and \(\tilde{k}\) running over each Brillouin zone (BZ) sector. \(\omega_{n}\) is the Matsubara frequency, \(\mu\) is the chemical potential, \(\epsilon_{k+\tilde{k},\nu}^{\sigma}\) are the Kohn-Sham (KS) eigenvalues, and \(\Delta_{\nu,\nu'}^{\sigma}(k+\tilde{k},\omega_{n})\) is the lattice self-energy which is calculated as an expansion of the cluster self-energy over the Bloch basis set:

\[
\Delta_{\nu,\nu'}^{\sigma}(k+\tilde{k},\omega_{n}) = \sum_{\alpha,m,m'} P_{\nu,m}^{\alpha,\sigma}(k+\tilde{k}) \Delta \Sigma_{m,m'}^{\sigma,\text{imp}}(K,\omega_{n}) P_{m',\nu'}^{\alpha,\sigma}(k+\tilde{k}).
\]

From the self-energy we need to subtract the contribution to correlations that is already included in the LDA calculation, commonly called double counting (DC) correction,

\[
\Delta \Sigma_{m,m'}^{\text{imp}}(K,\omega_{n}) = \Sigma_{m,m'}^{\text{imp}}(K,\omega_{n}) - \Sigma_{\text{dc}},
\]

where \(\Sigma_{m,m'}^{\text{imp}}(K,\omega_{n})\) is calculated by the continuous time Quantum Monte Carlo (CT-QMC) cluster solver and the Dyson’s equation. Calculating the DC correction is not possible exactly, but some approximate expressions have been introduced. Here, we use as double counting correction

\[
\Sigma_{m,m'}^{\sigma,\text{dc}} = \delta_{m,m'} \left[ U'\left( N_{c} - \frac{1}{2} \right) - J \left( N_{\sigma} - \frac{1}{2} \right) \right],
\]

where \(U' = U - 2J\), \(U\) is the onsite Coulomb interaction, \(J\) is the Hund’s coupling and \(N_{c}\) and \(N_{\sigma}\) denote the number of total occupied states and spin-resolved occupied states in the correlated orbitals, respectively\(^{33}\). The local cluster Green’s functions are given as

\[
G_{m,m'}^{\sigma,\text{loc}}(k,\omega_{n}) = \sum_{k,\nu,\nu'} P_{m,\nu}^{\alpha,\sigma}(K + \tilde{k}) G_{\nu,\nu'}^{\sigma}(K + \tilde{k},\omega_{n}) P_{\nu',m'}^{\alpha,\sigma'}(K + \tilde{k}),
\]

where the summation over \(\tilde{k}\) is calculated in each Brillouin zone sector. The LDA+DCA self-consistency condition states that this local cluster Green’s functions, Eq. (5), have to be equal to the impurity Green’s functions as calculated by CT-QMC. The DMFT update of the Weiss field is given by the Dyson’s equation as

\[
[G_{m,m'}^{\sigma}(K,\omega_{n})]^{-1} = \Sigma_{m,m'}^{\sigma,\text{imp}}(K,\omega_{n}) + \left[G_{m,m'}^{\sigma,\text{loc}}(K,\omega_{n})\right]^{-1}.
\]

B. Many-body interactions and CT-QMC algorithm

In order to describe the electronic behavior of SrVO\(_3\) one has to consider the multiorbital Hubbard Hamiltonian where the interaction term is given by:

\[
H_{I} = U \sum_{m} n_{m}^{\uparrow} n_{m}^{\downarrow} + \sum_{m<n,\sigma} \left[ (U' - J) n_{m}^{\sigma} n_{n}^{\bar{\sigma}} - J' c_{n}^{\sigma} c_{\bar{m}}^{\bar{\sigma}} c_{m}^{\bar{\sigma}} c_{n}^{\sigma} ight],
\]

and \(m, n\) denote the \(t_{2g}\) orbitals. In order to solve this model we employ a weak-coupling CT-QMC algorithm. While the weak-coupling CT-QMC algorithm can easily treat a multiple number of sites in the cluster, it is difficult to deal with the full rotationally invariant form of the interaction Hamiltonian due to the fermionic sign problem, in contrast to the strong-coupling CT-QMC algorithm\(^{49,50}\). Therefore, in what follows we shall consider a simplified Hubbard model where the spin-flip and pairing terms in Eq. (10) are neglected (\(J' = 0\)).

The main idea of the weak-coupling CT-QMC method is to divide the total action \(S\) into an unperturbed term
and the interaction term $I$ which is expanded in a Taylor series. The partition function is rewritten as

$$Z = \sum_k Z_0 \frac{(-I)^k}{k!} \int d\tau_1 \cdots d\tau_k \int D[c, \bar{c}]$$

$$\langle u_{\tau_1} n_{\tau_1} \cdots u_{\tau_k} n_{\tau_k} \rangle,$$

where $\langle u_{\tau_1} n_{\tau_1} \cdots u_{\tau_k} n_{\tau_k} \rangle$ is determined by the non-interacting Green’s function and Wick’s theorem, $k$ is the perturbation order, $Z_0 = \text{Tr}(e^{-S})$ corresponds to the unperturbed term and $l$, $l'$ and $\tau_k$ are randomly sampled. $I$ is given as

$$I = \bar{U} \beta N M(2M - 1),$$

where $\beta$ is the inverse temperature, $N$ and $M$ are the number of sites and the number of orbitals in the cluster, respectively, and $U$ is one of $U$, $U'$ or $U' - J$ depending on the operators considered in the random walk in the average $\langle \cdots \rangle$ in Eq. (11). The impurity Green’s functions are calculated by numerically averaging Eq. (11).

### III. RESULTS

SrVO$_3$, which is thought to be a prototypical paramagnetic correlated metal with intermediate electron-electron interactions, has served in the past as a testing ground for numerous newly developed LDA+DMFT approaches.$^{2,31–35,38}$ In SrVO$_3$, the V 3d-orbitals are split by the crystal field into triply degenerate $t_{2g}$ and doubly degenerate $e_g$ states. The LDA calculations show that the degenerate $t_{2g}$ states of V form bands crossing the Fermi level which are well separated from the $e_g$ bands.

For our calculations on SrVO$_3$, we chose the energy window $W$ from -1.35 eV to 2.0 eV for the $t_{2g}$ orbitals which can then be effectively described by the degenerate three-orbital Hubbard model in Eq. (10). We first reproduced the results of LDA+DMFT from Ref. $^{31}$ considering a temperature $T = 0.1$ eV and the same Coulomb interaction $U = 4.0$ eV, and Hund’s rule coupling $J = 0.65$ eV. In a next step, we extend the LDA+DMFT solution to LDA+DCA with two sites in the cluster $N = 2$. Within the DCA method, $N = 2$ implies that we have two BZ sectors and the self-energies in the BZ sectors are constant.

The BZ of SrVO$_3$ has cubic symmetry and the self-energies in the cluster momenta $K_0 = (0,0,0)$ and $K_1 = (\pi,\pi,\pi)$ are calculated in the BZ sectors shown in Figs. 1(a) and (b). In real space, the on-site and nearest neighbor-site Green’s functions are $G_{R=0}(i\omega_n) = \frac{1}{2}(G_{K_0}(i\omega_n) + G_{K_1}(i\omega_n))$ and $G_{R=1}(i\omega_n) = \frac{1}{2}(G_{K_0}(i\omega_n) - G_{K_1}(i\omega_n))$, respectively. Here, the DCA formalism with $N = 2$ for cubic lattice has been clearly presented in Ref. $^{31}$. Both on-site and nearest neighbor-site Green’s functions are inserted into the CT-QMC impurity solver, and the LDA+DCA self-consistency is satisfied by Eqs. (5) and (6).

**FIG. 1.** (Color online) One quadrant of the Brillouin zone of SrVO$_3$. (a) and (b) represent the $K_0 = (0,0,0)$ and $K_1 = (\pi,\pi,\pi)$ Brillouin zone sectors, respectively. Other quadrants follow from symmetry.

**FIG. 2.** (Color online) (a) The density of states $\rho(\omega)$ of SrVO$_3$ calculated within the LDA+DMFT and LDA+DCA approaches, with $U = 4.0$ eV, $J = 0.65$ eV and $T = 0.1$ eV. The density of states $\rho(\omega)$ for LDA+DCA is calculated by $\rho(\omega) = \frac{1}{2}(A(K_0,\omega) + A(K_1,\omega))$, with $K_0 = (0,0,0)$ and $K_1 = (\pi,\pi,\pi)$ sectors. (b) and (c) The spectral functions $A(K,\omega)$ obtained from LDA and LDA+DCA for the $K_0$ and $K_1$ sectors by Eq. (8), respectively. All the density of states and spectral functions are normalized to one.
Fig. 2(a) shows the density of states $\rho(\omega)$ of the vanadium $t_{2g}$ orbitals obtained within the LDA+DMFT, $\rho(\omega)= A(\omega)$ and LDA+DCA, $\rho(\omega) = \frac{1}{\pi} A(K_0, \omega) + A(K_1, \omega)$). Here, the spectral function $A(K, \omega)$ is given as
\begin{equation}
A(K, \omega) = -\frac{1}{\pi} \text{Im} G_K(\omega),
\end{equation}
and an analytical continuation of the impurity Green’s functions is performed through a maximum entropy method. Our LDA+DMFT results obtained by both the weak-coupling CT-QMC54,55 as well as the strong-coupling CT-QMC algorithms from the ALPS code56 agree with former LDA+DMFT calculations2,31,33,35. In Figs. 2(b) and (c) we present the spectral functions for the $K_0 = (0,0,0)$ and $K_1 = (\pi, \pi, \pi)$ sectors within LDA and LDA+DCA. The new features obtained in LDA+DCA are a broad peak around 1.5 eV and a coherent peak around 0.2 eV below $E_F$. LDA results (see Fig. 2(b)) as well as most former LDA+DMFT results (see also Fig. 2(a)) don’t exhibit neither a broad peak nor a clear coherent peak below $E_F$. Recent angle resolved photoemission (ARPES) experiments57, have observed, in fact, a broad peak around 1.5 eV and a coherent peak around 0.4 eV below $E_F$ (Fig. 3(b) in Ref. 53). We suggest that the better agreement of the LDA+DCA with ARPES observations is a consequence of the inclusion of short-range spatial correlations. Fig. 2(c) shows that the coherent and broad peaks below the Fermi level are caused by the distinct spectral weights in the $K_0 = (0,0,0)$ and $K_1 = (\pi, \pi, \pi)$ sectors. These two sectors also show respectively metallic and band insulating behavior reminiscent of the LDA results in these sectors (Fig 2(b) and Ref. 54).

In Figs. 3(a) and 3(b), we show the momentum resolved spectral functions calculated from Eq. 6 and Eq. 8. The analytical continuation of the self-energy $\Sigma(K, i\omega_n)$ is performed by the maximum entropy approach with subtraction of the Hartree-Fock term55. In view of the ill-posed problem of the analytical continuation of the self-energy56, we also compared the DOS obtained from integration of the spectral functions with those in Fig. 2(a) and found a reasonable agreement. We also compare LDA+DMFT to LDA+DCA results. One can observe some redistribution of momentum resolved spectral weight between the LDA+DMFT and LDA+DCA results. In Figs. 3(c) and 3(d) we plot the LDA+DMFT and LDA+DCA spectral functions respectively, in the region where $k_y = -0.6\pi$ and $0.4\pi$ at $k_z = 0.0$ and $k_z = 0.32\pi$ (a is the lattice constant) in order to directly compare our calculations to the ARPES results (Fig. 1 (a) of Ref. 54). In agreement with ARPES experiments, both LDA+DMFT and LDA+DCA show dispersive features around -0.7 though they are more pronounced in the LDA+DCA calculations. Also, the LDA+DCA calculations reproduce the small peak observed around -0.2eV. These results account for the renormalization of the bands due to electronic correlations.

Finally, our estimation of the mass enhancement is $m^*/m \approx 1.7 \pm 0.3$ within LDA+DMFT and $1.6 \pm 0.5$ within LDA+DCA at $K_0 = (0,0,0)$. These values are obtained from
\begin{equation}
m^*/m \approx 1 - \frac{\partial \text{Im} \Sigma(i\omega_n)}{\partial \omega} \bigg|_{\omega \rightarrow 0^+},
\end{equation}
where the derivative is extracted by fitting a third-order polynomial to the lowest four Matsubara frequencies55. Note that our LDA+DCA estimates give a slightly smaller mass enhancement than LDA+DMFT estimates with a larger error bar. Both sets of results are in accordance with ARPES estimates of $m^*/m \approx 1.8 \pm 0.258$.

IV. CONCLUSIONS

In conclusion, we have presented an implementation of the LDA+DCA method within the linear augmented plane-wave framework. We have compared our benchmark results on SrVO$_3$, which is modeled in terms of a three-band Hubbard Hamiltonian, with earlier LDA+DMFT calculations as well as experimental data. Since the LDA+DCA approach considers both local quantum as well as short-range spatial fluctuations, it offers a more complete description of correlated materials compared to the LDA+DMFT approach, where only local quantum fluctuations are taken into account.

Unlike the LDA+DMFT, the LDA+DCA approach reproduces both coherent and broad peaks for SrVO$_3$ be-
low the Fermi level, observed in angle integrated photoemission experiments. The analysis of the spectral functions at $K_0 = (0,0,0)$ and $K_1 = (\pi, \pi, \pi)$ reveals the source of these peaks. While the broad peak is due to the spectral function in the $K_0 = (0,0,0)$ sector, the coherent peak has its origin in the spectral function at the $K_1 = (\pi, \pi, \pi)$ sector. We also observe a metallic and a band insulating state at the $K_0 = (0,0,0)$ and $K_1 = (\pi, \pi, \pi)$ sectors, also present in the LDA results.

In summary, we believe that the presented LDA+DCA approach is very promising and can be applied to a large variety of multiorbital correlated compounds at different fillings.

V. ACKNOWLEDGEMENTS

We would like to thank Y.-Z. Zhang and C. Gros for useful discussions and we gratefully acknowledge financial support from the Deutsche Forschungsgemeinschaft through grants FOR 1346 (H.L.) and SPP 1458 (J.F.) and from the Helmholtz Association through grant HA216/EMMI. M.A. acknowledges support from the Austrian Science Fund, project F4103, and hospitality at Goethe-Universität Frankfurt.
