Quark Mass Hierarchies and Maximal $CP$–Violation

Harald Fritzsch

Abstract
It is argued taking into account the observed mass spectra of the leptons and quarks that the phenomenon of flavor mixing is intimately related to the mass spectra. We discuss a particularly interesting way to describe the flavor mixing which is particularly suited for models of quark mass matrices based on flavor symmetries. $CP$ violated is maximal or class to being maximal in our approach.

At the end of the last century, exactly hundred years ago, physicists were confronted with the puzzles of the atomic substructure and with the perplexing structure of the atomic spectra. Finally, more than 20 years later, all these complexities were understood in terms of a few parameters like $\hbar$, $\alpha$ and the electron mass. Today we are facing similar complexities – the puzzles of the quark and lepton mass spectra and the nature of flavor mixing. After the discovery of the $t$–quark the spectrum of the masses (apart from the yet unknown neutrino masses) is known. It is a rather wild spectrum, extending over 5 orders of magnitude, from the tiny electron mass to the huge $t$–mass, but the actual dynamics behind this spectrum remains mysterious. Nature speaks to us in some kind of mysterious language. The letters of this language, i. e. the masses and flavor mixing parameters, are known, but the grammar and the content of the underlying text are unknown.

Of course, in this lecture I cannot offer a complete solution of the mass problem, but I shall describe what I would like to define as the grammar of patterns and rules, which are not only very simple, but seem to come well, if confronted with the experimental results.

The phenomenon of flavor mixing, which is intrinsically linked to $CP$–violation, is an important ingredient of the Standard Model of Basic Interactions. Yet unlike other features of the Standard Model, e. g. the mixing of the neutral electroweak gauge bosons, it is a phenomenon which can merely be described. A deeper understanding is still lacking, but it is clearly directly linked to the mass spectrum of the quarks. Furthermore there is a general consensus that a deeper dynamical understanding would require to go beyond the physics of the Standard Model. In my lectures I shall not go thus far. Instead I
shall demonstrate that the observed properties of the flavor mixing, combined with our knowledge about the quark mass spectrum, suggest specific symmetry properties which allow to fix the flavor mixing parameters with high precision, thus predicting the outcome of the experiments which will soon be performed at the B–meson factories.

Before we enter the field of fermion mass generation, flavor mixing and CP–violation, let me make some general remarks about the mass issue as it appears today. The gauge interactions of the Standard Model are relevant both for the lefthanded (L) and righthanded (R) fermion fields. Chirality is conserved by the gauge interaction – a lefthanded quark, after interacting with a gauge boson, e. g. a W–boson or a gluon, stays lefthanded. A CP–transformation turns a lefthanded quark into a righthanded antiquark, but the interaction with the gauge bosons is unaffected. Thus the gauge sector of the Standard Model can be divided into two disjoint worlds, the world of L–fermions and of R–fermions. Formally the gauge interactions do not provide a bridge between those two sectors.

In reality the situation is more complex, which can be observed in particular by looking at the strong interactions. In the limit in which the quarks are taken to be massless (limit of chiral SU(n)_L × SU(n)_R) the world of QCD can also be divided up into the world of L–quarks and of R–quarks. However nonperturbative effects generate a non–zero value for the v. e. v. of \( \bar{q}_R q_L \):

\[
<0 \mid \bar{q}_R q_L + h.c. \mid 0 > \neq 0,
\]

which is given in terms of \( \Lambda_c \) (\( \Lambda_c \): QCD scale). Thus there exists a strong correlation between the lefthanded and righthanded fields, which is responsible for the mass generation of the bound states like the proton or the \( \rho \)–meson. These masses are due to the dynamical breaking of the chiral symmetry.

A consequence of this symmetry breaking is that the matrix elements of the axial vector currents acquire a pole at \( q^2 = 0 \) (\( q \): momentum transfer), due to the massless pseudoscalar mesons which serve as the corresponding Goldstone particles.

In the Standard Model of the electroweak interaction the masses are introduced by the coupling of the gauge fields and fermions to the scalar field \( \varphi \) whose neutral component \( \varphi^0 \) acquires a non–zero v.e.v.:

\[
<0 \mid \varphi^0 \mid 0 > = \frac{1}{\sqrt{2}} v
\]

In order to reproduce the observed gauge boson masses, one needs to have \( v \approx 246 \) GeV.

The quark and lepton masses are introduced by the coupling of the fermions to \( \varphi \), which is described by a coupling constant which is a free parameter and varies for the different
fermions in proportion to the masses. These couplings of the type

$$\lambda \cdot \bar{\psi}_R \psi_L \varphi + \text{h.c.}$$

provide a correlation between the $L$–world and the $R$–world. The v.e.v. of $\varphi$, multiplied with $\lambda$ describes the corresponding fermion mass. Since the coupling constants $\lambda$ can be complex, the $CP$–symmetry will be violated, if there are more than two families of fermions, and if flavor mixing is present.

In the Standard Model the fermion masses are introduced via the spontaneous symmetry breaking in order to ensure the renormalizability of the underlying gauge theory. However, it can be seen from a more general point of view that the introduction of the fermion masses in the electroweak gauge theory is a dynamical issue, unlike the introduction of the quark masses in QCD. Let us consider a “gedankenexperiment”, the process $\bar{t}t \rightarrow W^+W^-$, in which both incoming quarks are polarized. In the center of mass frame we prepare the outgoing $W$–bosons in a $J = 1$ wave by colliding both a $t_L$–quark and a $\bar{t}_R$–quark. The tree-diagrams describing the process are either the formation of a virtual $\gamma$ or $Z$, decaying into the $W$–pair, or the exchange of a $b$–quark in the $t$–channel, leading to the production of the $W$–pair. Both diagrams, if considered in isolation, lead to a cross section which violates the unitarity bound for $J = 1$ at high energy, but the coherent sum does not. This is the famous gauge theory cancellation.

The dynamical aspect of the $t$–mass enters, if we study the $W^+W^-$–production in the $J = 0$ wave by considering the process $t_L \bar{t}_L \rightarrow W^+W^-$. Since $\bar{t}_L$–quarks do not interact with the $W$–bosons, the cross section in the $J = 0$ wave would vanish for massless $t$–quarks. However, due to the non–zero $t$–mass, a $t$–quark prepared in the center–of–mass system with its spin opposite to its momentum has a righthanded component, and the scattering amplitude in the $s$–wave is proportional to $m_t \cdot \sqrt{s}$. Thus unitarity is violated at high energy.

In the Standard Model this problem is avoided, since there is a cancellation in the $J = 0$ channel provided by the scalar “Higgs”–particle. The coupling of the latter to the $t$–quark is proportional to $m_t$. Hence the cancellation is present, no matter how large $m_t$ is.

This simple “Gedankenexperiment” shows the general condition: The cross section for the reaction $\bar{t}t \rightarrow W^+W$ in the $s$–wave must be finite at high energies. This requires a new dynamics besides the one provided by the quarks and electroweak gauge bosons. It could be either the addition of a new scalar particle, as in the Standard Model, or a string of resonances in the $J = 0$ channel, generated by new types of interactions or, perhaps, a new substructure of the leptons and quarks. At present we do not know, which possibility is realized, but in general it is implied that the lepton and quark masses are more than just kinematical quantities. They must play an essential rôle in the dynamics. For this
reason one should expect that the fermion masses, especially the $t$-mass, are linked in a specific way to the masses of the $W$-bosons, but the details of such a link are not known.

After these introductory remarks about the rôle of the lepton and quark masses in the electroweak gauge theory, let me turn to the main topic of these lectures, the connection between quark masses and the mixing of the quark flavors. According to the standard electroweak theory one is dealing with three $SU(2)_w$-doublets:

\[
\begin{pmatrix}
  u' \\
  d'
\end{pmatrix}_L \begin{pmatrix}
  c' \\
  s'
\end{pmatrix}_L \begin{pmatrix}
  t' \\
  b'
\end{pmatrix}_L
\]

where $u', d', ...$ stand for certain superpositions of the corresponding mass eigenstates. In terms of mass eigenstates the charged weak currents are given by:

\[
(u, c, t)_L \begin{pmatrix}
  V_{ud} & V_{us} & V_{ub} \\
  V_{cd} & V_{cs} & V_{cb} \\
  V_{td} & V_{ts} & V_{tb}
\end{pmatrix} \begin{pmatrix}
  d \\
  s \\
  s
\end{pmatrix}_L.
\]

This generalizes the standard Cabibbo–type rotation between the first and second family\(^1\). The matrix elements $V_{ij}$ are the elements of the CKM matrix\(^2\). In general they are complex numbers. Their absolute values are measurable quantities. For example, $|V_{cb}|$ primarily determines the lifetime of $B$ mesons. The phases of $V_{ij}$, however, are not physical, like the phases of quark fields. A phase transformation of the $u$ quark ($u \to u e^{i\alpha}$), for example, leaves the quark mass term invariant but changes the elements in the first row of $V$ (i.e., $V_{uj} \to V_{uj} e^{-i\alpha}$). Only a common phase transformation of all quark fields leaves all elements of $V$ invariant, thus there is a five-fold freedom to adjust the phases of $V_{ij}$.

In general the unitary matrix $V$ depends on nine parameters. Note that in the absence of complex phases $V$ would consist of only three independent parameters, corresponding to three (Euler) rotation angles. Hence one can describe the complex matrix $V$ by three angles and six phases. Due to the freedom in redefining the quark field phases, five of the six phases in $V$ can be absorbed and we arrive at the well-known result that the CKM matrix $V$ can be parametrized in terms of three rotation angles and one $CP$-violating phase\(^2\).

The standard parametrization of the CKM matrix is given as follows:

\[
V_{ij} = \begin{pmatrix}
  c_{12} c_{13} & s_{12} c_{13} & s_{13} e^{-i\delta_{13}} \\
  -s_{12} c_{23} - c_{12} s_{23} s_{13} e^{i\delta_{13}} & c_{12} c_{23} - s_{12} s_{23} s_{13} e^{i\delta_{13}} & s_{23} c_{13} \\
  s_{12} s_{23} - c_{12} c_{23} s_{13} e^{i\delta_{13}} & -c_{12} s_{23} - s_{12} c_{23} s_{13} e^{i\delta_{13}} & c_{23} c_{13}
\end{pmatrix}
\]

Here $s_{12}$ stands for $\sin\Theta_{12}$, $c_{12}$ for $\cos\Theta_{12}$ etc. Since the observed mixing angles are small
the three angles $\Theta_{12}, \Theta_{23}$ and $\Theta_{13}$ are related in a good approximation to the moduli of specific $V$–elements as follows:

$$|V_{us}| \cong s_{12}, \quad |V_{ub}| \cong s_{13}, \quad |V_{cb}| \cong s_{23}. \quad (7)$$

The experiments give$^3$:

$$\Theta_{12} \cong 12.7^\circ, \quad \Theta_{13} \cong 0.18^\circ, \quad \Theta_{23} \cong 2.25^\circ. \quad (8)$$

(Here we have given the central values of these angles for illustration, without indicating the errors. The phase $\delta_{13}$ angle will be discussed later).

Another way to describe the flavor mixing matrix is to follow Wolfenstein$^4$ and to use the modulus of $V_{us}$ as an expansion parameter:

$$V = \begin{pmatrix} 1 - \frac{1}{2} \lambda^2 & \lambda & A \lambda^3 (\rho - i\eta) \\ -\lambda & 1 - \frac{1}{2} \lambda^2 & A \lambda^2 \\ A \lambda^3 (1 - \rho - i\eta) & -A \lambda^2 & 1 \end{pmatrix} + O(\lambda^4) \quad (9)$$

The central values of the parameters are:

$$\lambda = 0.2205, \quad A = 0.806, \quad |\rho - i\eta| = 0.36. \quad (10)$$

When the standard parametrization of the CKM–matrix in terms of the angles $\Theta_{ij}$ was introduced years ago by a number of authors including this one$^5$, the large value of the $t$–mass was not known. Thus the striking mass hierarchy exhibited in the quark mass spectrum was not explicitly taken into account. But the flavor mixing and the mass spectrum are intimately related to each other, and the question arises whether the standard way of describing the flavor mixing is the best way in doing so. We shall discuss this issue below. The same question can be asked for the other description proposed in the literature, e.g. the original one given by Kobayashi and Maskawa$^2$ or the one given recently$^6$.

Adopting a particular parametrization of flavor mixing is arbitrary and not directly a physical issue. Nevertheless it is quite likely that the actual values of flavor mixing parameters (including the strength of $CP$–violation), once they are known with high precision, will give interesting information about the physics beyond the standard model. Probably at this point it will turn out that a particular description of the CKM matrix is more useful and transparent than the others. This is of special interest for the phase parameter describing $CP$–violation. There are many different ways to parametrize the phase parameter relevant for $CP$ violation, like there are in principle many different ways to describe the parity violation in nuclear transition amplitudes, for example by a phase
angle. But only one parametrization will be useful at the end, the one which is intrinsically linked to the physical origin of \( CP \)-violation. In the case of parity violation it is the phase angle between the vector and axialvector currents which is ninety degrees such that the weak interaction amplitude is given by lefthanded quark fields. Later I shall show that something similar might be true for \( CP \)-violation. Let me first analyze all possible parametrizations and point out their respective advantages and disadvantages.

The question about how many different ways to describe \( V \) may exist was raised some time ago\(^7\). Below we shall reconsider this problem and give a complete analysis.

If the flavor mixing matrix \( V \) is first assumed to be a real orthogonal matrix, it can in general be written as a product of three matrices \( R_{12}, R_{23} \) and \( R_{31} \), which describe simple rotations in the (1,2), (2,3) and (3,1) planes:

\[
R_{12}(\theta) = \begin{pmatrix} c_{\theta} & s_{\theta} & 0 \\ -s_{\theta} & c_{\theta} & 0 \\ 0 & 0 & 1 \end{pmatrix},
\]

\[
R_{23}(\sigma) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & c_{\sigma} & s_{\sigma} \\ 0 & -s_{\sigma} & c_{\sigma} \end{pmatrix},
\]

\[
R_{31}(\tau) = \begin{pmatrix} c_{\tau} & 0 & s_{\tau} \\ 0 & 1 & 0 \\ -s_{\tau} & 0 & c_{\tau} \end{pmatrix}, \tag{11}
\]

where \( s_{\theta} \equiv \sin \theta, c_{\theta} \equiv \cos \theta \), etc. Clearly these rotation matrices do not commute with each other. There exist twelve different ways to arrange products of these matrices such that the most general orthogonal matrix \( R \) can be obtained. Note that the matrix \( R_{ij}^{-1}(\omega) \) plays an equivalent role as \( R_{ij}(\omega) \) in constructing \( R \), because of \( R_{ij}^{-1}(\omega) = R_{ij}(-\omega) \). Note also that \( R_{ij}(\omega)R_{ij}(\omega') = R_{ij}(\omega + \omega') \) holds, thus the product \( R_{ij}(\omega)R_{ij}(\omega')R_{kl}(\omega'') \) or \( R_{kl}(\omega'')R_{ij}(\omega)R_{ij}(\omega') \) cannot cover the whole space of a \( 3 \times 3 \) orthogonal matrix and should be excluded. Explicitly the twelve different forms of \( R \) read as

\[
\begin{align*}
(1) & \quad R = R_{12}(\theta) \ R_{23}(\sigma) \ R_{12}(\theta'), \\
(2) & \quad R = R_{12}(\theta) \ R_{31}(\tau) \ R_{12}(\theta'), \\
(3) & \quad R = R_{23}(\sigma) \ R_{12}(\theta) \ R_{23}(\sigma'), \\
(4) & \quad R = R_{23}(\sigma) \ R_{31}(\tau) \ R_{23}(\sigma'), \\
(5) & \quad R = R_{31}(\tau) \ R_{12}(\theta) \ R_{31}(\tau'), \\
(6) & \quad R = R_{31}(\tau) \ R_{23}(\sigma) \ R_{31}(\tau').
\end{align*}
\]
in which a rotation in the \((i, j)\) plane occurs twice; and

1. \(R = R_{12}(\theta) R_{23}(\sigma) R_{31}(\tau)\),
2. \(R = R_{12}(\theta) R_{31}(\tau) R_{23}(\sigma)\),
3. \(R = R_{23}(\sigma) R_{12}(\theta) R_{31}(\tau)\),
4. \(R = R_{12}(\theta) R_{12}(\theta) R_{23}(\sigma)\),
5. \(R = R_{31}(\tau) R_{12}(\theta) R_{23}(\sigma)\),
6. \(R = R_{31}(\tau) R_{23}(\sigma) R_{12}(\theta)\),

where all three \(R_{ij}\) are present.

Although all the above twelve combinations represent the most general orthogonal matrices, only nine of them are structurally different. The reason is that the products \(R_{ij} R_{kl} R_{ij}\) and \(R_{ij} R_{mn} R_{ij}\) (with \(ij \neq kl \neq mn\)) are correlated with each other, leading essentially to the same form for \(R_{ij}\). Indeed it is straightforward to see the correlation between patterns (1), (3), (5) and (2), (4), (6), respectively, as follows:

1. \(R_{12}(\theta) R_{31}(\tau) R_{12}(\theta') = R_{12}(\theta + \pi/2) R_{23}(\sigma = \tau) R_{12}(\theta' - \pi/2)\),
2. \(R_{23}(\sigma) R_{31}(\tau) R_{23}(\sigma') = R_{23}(\sigma - \pi/2) R_{12}(\theta = \tau) R_{23}(\sigma' + \pi/2)\),
3. \(R_{31}(\tau) R_{23}(\sigma) R_{31}(\tau') = R_{31}(\tau + \pi/2) R_{12}(\theta = \sigma) R_{31}(\tau' - \pi/2)\).

Thus the orthogonal matrices (2), (4) and (6) need not be treated as independent choices.

We then draw the conclusion that there exist nine different forms for the orthogonal matrix \(R\), i.e., patterns (1), (3) and (5) as well as (7) – (12).

We proceed to include the \(CP\)-violating phase, denoted by \(\varphi\), in the above rotation matrices. The resultant matrices should be unitary such that a unitary flavor mixing matrix can be finally produced. There are several different ways for \(\varphi\) to enter \(R_{12}\), e.g.,

\[
R_{12}(\theta, \varphi) = \begin{pmatrix}
c_\theta & s_\theta e^{i\varphi} & 0 \\
-s_\theta e^{-i\varphi} & c_\theta & 0 \\
0 & 0 & 1
\end{pmatrix},
\]

or

\[
R_{12}(\theta, \varphi) = \begin{pmatrix}
c_\theta & s_\theta & 0 \\
-s_\theta & c_\theta & 0 \\
0 & 0 & e^{-i\varphi}
\end{pmatrix},
\]

or

\[
R_{12}(\theta, \varphi) = \begin{pmatrix}
c_\theta e^{+i\varphi} & s_\theta & 0 \\
-s_\theta & c_\theta & 0 \\
0 & 0 & 1
\end{pmatrix}.
\]

Similarly one may introduce a phase parameter into \(R_{23}\) or \(R_{31}\). Then the CKM matrix \(V\) can be constructed, as a product of three rotation matrices, by use of one complex \(R_{ij}\).
and two real ones. Note that the location of the $CP$-violating phase in $V$ can be arranged by redefining the quark field phases, thus it does not play an essential role in classifying different parametrizations. We find that it is always possible to locate the phase parameter $\varphi$ in a $2 \times 2$ submatrix of $V$, in which each element is a sum of two terms with the relative phase $\varphi$. The remaining five elements of $V$ are real in such a phase assignment. Accordingly we arrive at nine distinctive parametrizations of the CKM matrix $V$, where the complex rotation matrices $R_{12}(\theta, \varphi)$, $R_{23}(\sigma, \varphi)$ and $R_{31}(\tau, \varphi)$ are obtained directly from the real ones in Eq. (11) with the replacement $1 \rightarrow e^{-i\varphi}$. These nine possibilities have been discussed recently in $^8,^9$.

From a mathematical point of view, all nine different parametrizations are equivalent. However this is not the case if we apply our considerations to the quarks and their mass spectrum. It is well–known that both the observed quark mass spectrum and the observed values of the flavor mixing parameters exhibit a striking hierarchical structure. The latter can be understood in a natural way as the consequence of a specific pattern of chiral symmetries whose breaking causes the towers of different masses to appear step by step$^{10,11,12}$. Such a chiral evolution of the mass matrices leads to a specific way to introduce and describe the flavor mixing$^{11}$. 

In the limit $m_u = m_d = 0$, which is close to the real world, since $m_u/m_t \ll 1$ and $m_d/m_b \ll 1$, the flavor mixing is merely a rotation between the $t$–$c$ and $b$–$s$ systems, described by one rotation angle. No complex phase is present; i.e., $CP$ violation is absent. This rotation angle is expected to change very little, once $m_u$ and $m_d$ are introduced as tiny perturbations. A sensible parametrization should make use of this feature. This implies that the rotation matrix $R_{23}$ appears exactly once in the description of the CKM matrix $V$, eliminating two among the nine possibilities. This leaves us with seven parametrizations of the flavor mixing matrix.

The list can be reduced further by considering the location of the phase $\varphi$. In the limit $m_u = m_d = 0$, the phase must disappear in the weak transition elements $V_{tb}$, $V_{ts}$, $V_{cb}$ and $V_{cs}$. This eliminates four possibilities. Then we are left with three parametrizations. As expected, these are the parametrizations containing the complex rotation matrix $R_{23}(\sigma, \varphi)$. We stress that the “standard” parametrization does not obey the above constraints and should be dismissed.

Among the remaining three parametrizations, one parametrization is singled out by the fact that the $CP$-violating phase $\varphi$ appears only in the $2 \times 2$ submatrix of $V$ describing the weak transitions among the light quarks. This is precisely the phase where the phase $\varphi$ should appear, not in any of the weak transition elements involving the heavy quarks $t$ and $b$. 

In the two other parametrizations the complex phase $\phi$ appears in $V_{cb}$ or $V_{ts}$, but this phase factor is multiplied by a product of $\sin \theta$ and $\sin \tau$, i.e., it is of second order of the weak mixing angles. Hence the imaginary parts of these elements are not exactly vanishing, but very small in magnitude.

In our view the best possibility to describe the flavor mixing in the standard model is to adopt the remaining parametrization$^8). This parametrization has a number of significant advantages in addition to that mentioned above. Especially it is well suited for specific models of quark mass matrices.

In the following part I shall show that this parametrization follows automatically, if we impose the constraints from the chiral symmetries and the hierarchical structure of the mass eigenvalues. We take the point of view that the quark mass eigenvalues are dynamical entities, and one could change their values in order to study certain symmetry limits, as it is done in QCD. In the standard electroweak model, in which the quark mass matrices are given by the coupling of a scalar field to various quark fields, this can certainly be done by adjusting the related coupling constants. Whether it is possible in reality is an open question. It is well-known that the quark mass matrices can always be made hermitian by a suitable transformation of the right–handed fields. Without loss of generality, we shall suppose in this paper that the quark mass matrices are hermitian. In the limit where the masses of the $u$ and $d$ quarks are set to zero, the quark mass matrix $\tilde{M}$ (for both charge $+2/3$ and charge $-1/3$ sectors) can be arranged such that its elements $\tilde{M}_{ii}$ and $\tilde{M}_{1i}$ ($i = 1, 2, 3$) are all zero$^{10),11)$. Thus the quark mass matrices have the form

$$\tilde{M} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \tilde{C} & \tilde{B} \\ 0 & \tilde{B}^* & \tilde{A} \end{pmatrix}. \tag{14}$$

The observed mass hierarchy is incorporated into this structure by denoting the entry which is of the order of the $t$-quark or $b$-quark mass by $\tilde{A}$, with $\tilde{A} \gg \tilde{C}, |\tilde{B}|$. It can easily be seen$^9)$ that the complex phases in the mass matrices (14) can be rotated away by subjecting both $\tilde{M}_u$ and $\tilde{M}_d$ to the same unitary transformation. Thus we shall take $\tilde{B}$ to be real for both up- and down-quark sectors. As expected, $CP$ violation cannot arise at this stage. The diagonalization of the mass matrices leads to a mixing between the second and third families, described by an angle $\tilde{\theta}$. The flavor mixing matrix is then given by

$$\tilde{V} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \tilde{c} & \tilde{s} \\ 0 & -\tilde{s} & \tilde{c} \end{pmatrix}, \tag{15}$$

where $\tilde{s} \equiv \sin \tilde{\theta}$ and $\tilde{c} \equiv \cos \tilde{\theta}$. In view of the fact that the limit $m_u = m_d = 0$ is not far from reality, the angle $\tilde{\theta}$ is essentially given$^{13)$ by the observed value of $|V_{cb}|$ ($= 0.039 \pm 0.002$; i.e., $\tilde{\theta} = 2.24^\circ \pm 0.12^\circ$).
At the next and final stage of the chiral evolution of the mass matrices, the masses of the $u$ and $d$ quarks are introduced. The Hermitian mass matrices have in general the form:

$$M = \begin{pmatrix} E & D & F^* \\ D^* & C & B \\ F^* & B^* & A \end{pmatrix}$$  \hfill (16)

with $A \gg C, |B| \gg E, |D|, |F|$. By a common unitary transformation of the up- and down-type quark fields, one can always arrange the mass matrices $M_u$ and $M_d$ in such a way that $F_u = F_d = 0$; i.e.,

$$M = \begin{pmatrix} E & D & 0 \\ D^* & C & B \\ 0 & B^* & A \end{pmatrix}. \hfill (17)$$

This can easily be seen as follows. If phases are neglected, the two symmetric mass matrices $M_u$ and $M_d$ can be transformed by an orthogonal transformation matrix $O$, which can be described by three angles such that they assume the form (17). The condition $F_u = F_d = 0$ gives two constraints for the three angles of $O$. If complex phases are allowed in $M_u$ and $M_d$, the condition $F_u = F_u^* = F_d = F_d^* = 0$ imposes four constraints, which can also be fulfilled, if $M_u$ and $M_d$ are subjected to a common unitary transformation matrix $U$. The latter depends on nine parameters. Three of them are not suitable for our purpose, since they are just diagonal phases; but the remaining six can be chosen such that the vanishing of $F_u$ and $F_d$ results.

The basis in which the mass matrices take the form (17) is a basis in the space of quark flavors, which in our view is of special interest. It is a basis in which the mass matrices exhibit two texture zeros, for both up- and down-type quark sectors. These, however, do not imply special relations among mass eigenvalues and flavor mixing parameters (as pointed out above). In this basis the mixing is of the “nearest neighbour” form, since the $(1,3)$ and $(3,1)$ elements of $M_u$ and $M_d$ vanish; no direct mixing between the heavy $t$ (or $b$) quark and the light $u$ (or $d$) quark is present. In certain models\textsuperscript{14,15}, this basis is indeed of particular interest, but we shall proceed without relying on a special texture models for the mass matrices.

A mass matrix of the type (17) can in the absence of complex phases be diagonalized by a rotation matrix, described only by two angles in the hierarchy limit of quark masses\textsuperscript{8). At first the off-diagonal element $B$ is rotated away by a rotation between the second and third families (angle $\theta_{23}$); at the second step the element $D$ is rotated away by a transformation of the first and second families (angle $\theta_{12}$). No rotation between the first and third families is required to an excellent degree of accuracy. The rotation matrix for this
sequence takes the form

\[
R = R_{12} R_{23} = \begin{pmatrix}
  c_{12} & s_{12} & 0 \\
  -s_{12} & c_{12} & 0 \\
  0 & 0 & 1
\end{pmatrix} \begin{pmatrix}
  1 & 0 & 0 \\
  0 & c_{23} & s_{23} \\
  0 & -s_{23} & c_{23}
\end{pmatrix} \begin{pmatrix}
  c_{12} & s_{12} c_{23} & s_{12} s_{23} \\
  -s_{12} & c_{12} c_{23} & c_{12} s_{23} \\
  0 & -s_{23} & c_{23}
\end{pmatrix},
\]

(18)

where \( c_{12} \equiv \cos \theta_{12}, \) \( s_{12} \equiv \sin \theta_{12}, \) etc. The flavor mixing matrix \( V \) is the product of two such matrices, one describing the rotation among the up-type quarks, and the other describing the rotation among the down-type quarks:

\[
V = R_{12}^u R_{23}^u (R_{23}^d)^{-1} (R_{12}^d)^{-1}.
\]

(19)

Note that \( V \) itself is exact, since a rotation between the first and third families can always be incorporated and absorbed through redefining the relevant rotation matrices. The product \( R_{23}^u (R_{23}^d)^{-1} \) can be written as a rotation matrix described by a single angle \( \theta \). In the limit \( m_u = m_d = 0 \), this is just the angle \( \tilde{\theta} \) encountered in Eq. (15). The angle which describes the \( R_{12}^u \) rotation shall be denoted by \( \theta_u \); the corresponding angle for the \( R_{12}^d \) rotation by \( \theta_d \). Thus in the absence of \( CP \)-violating phases the flavor mixing matrix takes the following specific form:

\[
V = \begin{pmatrix}
  c_u & s_u & 0 \\
  -s_u & c_u & 0 \\
  0 & 0 & 1
\end{pmatrix} \begin{pmatrix}
  1 & 0 & 0 \\
  0 & c & s \\
  0 & -s & c
\end{pmatrix} \begin{pmatrix}
  c_d & -s_d & 0 \\
  s_d & c_d & 0 \\
  0 & 0 & 1
\end{pmatrix}
\]

(20)

\[
= \begin{pmatrix}
  c_u s_d c + c_u c_d & s_u c_d c - c_u s_d & s_u s \\
  c_u s_d c - s_u c_d & c_u c_d c + s_u s_d & c_u s \\
  -s_d s & -c_d s & c
\end{pmatrix},
\]

where \( c_u \equiv \cos \theta_u, \) \( s_u \equiv \sin \theta_u, \) etc.

We proceed by including the phase parameters of the quark mass matrices in Eq. (17). Each mass matrix has in general two complex phases. But it can easily be seen that, by suitable rephasing of the quark fields, the flavor mixing matrix can finally be written in terms of only a single phase \( \varphi \) as follows:

\[
V = \begin{pmatrix}
  c_u & s_u & 0 \\
  -s_u & c_u & 0 \\
  0 & 0 & 1
\end{pmatrix} \begin{pmatrix}
  e^{-i \varphi} & 0 & 0 \\
  0 & c & s \\
  0 & -s & c
\end{pmatrix} \begin{pmatrix}
  c_d & -s_d & 0 \\
  s_d & c_d & 0 \\
  0 & 0 & 1
\end{pmatrix}
\]

(21)

\[
= \begin{pmatrix}
  c_u s_d c e^{-i \varphi} + c_u c_d & s_u c_d c - c_u s_d e^{-i \varphi} & s_u s \\
  c_u s_d c - s_u c_d e^{-i \varphi} & c_u c_d c + s_u s_d e^{-i \varphi} & c_u s \\
  -s_d s & -c_d s & c
\end{pmatrix}.
\]
Note that the three angles $\theta_u$, $\theta_d$ and $\theta$ in Eq. (21) can all be arranged to lie in the first quadrant through a suitable redefinition of quark field phases. Consequently all $s_u$, $s_d$, $s$ and $c_u$, $c_d$, $c$ are positive. The phase $\varphi$ can in general take values from 0 to $2\pi$; and $CP$ violation is present in weak interactions if $\varphi \neq 0, \pi$ and $2\pi$. The parametrization given above is the one which is left after passing through the various steps of elimination.

This representation of the flavor mixing matrix, in comparison with all other parametrizations discussed previously, has a number of interesting features which in our view make it very attractive and provide strong arguments for its use in future discussions of flavor mixing phenomena, in particular, those in $B$-meson physics. We shall discuss them below.

a) The flavor mixing matrix $V$ in Eq. (21) follows directly from the chiral expansion of the mass matrices. Thus it naturally takes into account the hierarchical structure of the quark mass spectrum.

b) The complex phase describing $CP$ violation ($\varphi$) appears only in the $(1,1)$, $(1,2)$, $(2,1)$ and $(2,2)$ elements of $V$, i.e., in the elements involving only the quarks of the first and second families. This is a natural description of $CP$ violation since in our hierarchical approach $CP$ violation is not directly linked to the third family, but rather to the first and second ones, and in particular to the mass terms of the $u$ and $d$ quarks.

It is instructive to consider the special case $s_u = s_d = s = 0$. Then the flavor mixing matrix $V$ takes the form

$$V = \begin{pmatrix} e^{-i\varphi} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$  \hspace{1cm} (22)

This matrix describes a phase change in the weak transition between $u$ and $d$, while no phase change is present in the transitions between $c$ and $s$ as well as $t$ and $b$. Of course, this effect can be absorbed in a phase change of the $u$- and $d$-quark fields, and no $CP$ violation is present. Once the angles $\theta_u$, $\theta_d$ and $\theta$ are introduced, however, $CP$ violation arises. It is due to a phase change in the weak transition between $u'$ and $d'$, where $u'$ and $d'$ are the rotated quark fields, obtained by applying the corresponding rotation matrices given in Eq. (21) to the quark mass eigenstates ($u'$: mainly $u$, small admixture of $c$; $d'$: mainly $d$, small admixture of $s$).

Since the mixing matrix elements involving $t$ or $b$ quark are real in the representation (21), one can find that the phase parameter of $B_q^0-\bar{B_q}^0$ mixing ($q = d$ or $s$), dominated by the box-diagram contributions in the standard model\(^3\), is essentially unity:

$$\begin{pmatrix} q \\ p \end{pmatrix}_{B_q} = \frac{V_{tb}^*V_{tq}}{V_{tb}^*V_{tb}} = 1.$$  \hspace{1cm} (23)

In most of other parametrizations of the flavor mixing matrix, however, the two rephasing-variant quantities $(q/p)_{B_d}$ and $(q/p)_{B_s}$ take different (maybe complex) values.
c) The dynamics of flavor mixing can easily be interpreted by considering certain limiting cases in Eq. (21). In the limit $\theta \to 0$ (i.e., $s \to 0$ and $c \to 1$), the flavor mixing is, of course, just a mixing between the first and second families, described by only one mixing angle (the Cabibbo angle $\theta_C$). It is a special and essential feature of the representation (21) that the Cabibbo angle is not a basic angle, used in the parametrization. The matrix element $V_{us}$ (or $V_{cd}$) is indeed a superposition of two terms including a phase. This feature arises naturally in our hierarchical approach, but it is not new. In many models of specific textures of mass matrices, it is indeed the case that the Cabibbo-type transition $V_{us}$ (or $V_{cd}$) is a superposition of several terms. At first, it was obtained by in the discussion of the two-family mixing\(^\text{16}\).

In the limit $\theta = 0$ considered here, one has $|V_{us}| = |V_{cd}| = \sin \theta_C \equiv s_C$ and

$$s_C = |s_u c_d - c_u s_d e^{-i\varphi}|.$$  \hspace{1cm} (24)

This relation describes a triangle in the complex plane, as illustrated in Fig. 1, which we shall denote as the “LQ–triangle” (“light quark triangle”). This triangle is a feature of the mixing of the first two families. Explicitly one has (for $s = 0$):

$$\tan \theta_C = \sqrt{\frac{\tan^2 \theta_u + \tan^2 \theta_d - 2 \tan \theta_u \tan \theta_d \cos \varphi}{1 + \tan^2 \theta_u \tan^2 \theta_d + 2 \tan \theta_u \tan \theta_d \cos \varphi}}.$$  \hspace{1cm} (25)

Certainly the flavor mixing matrix $V$ cannot accommodate $CP$ violation in this limit. However, the existence of $\varphi$ seems necessary in order to make Eq. (25) compatible with current data, as one can see below.

d) The three mixing angles $\theta$, $\theta_u$ and $\theta_d$ have a precise physical meaning. The angle $\theta$ describes the mixing between the second and third families, which is generated by the off-diagonal terms $B_u$ and $B_d$ in the up and down mass matrices of Eq. (17). We shall refer to this mixing involving $t$ and $b$ as the “heavy quark mixing”. The angle $\theta_u$, however, solely describes the $u$-$c$ mixing, corresponding to the $D_u$ term in $M_u$. We shall denote this as the “$u$-channel mixing”. The angle $\theta_d$ solely describes the $d$-$s$ mixing, corresponding to the $D_d$ term in $M_d$; this will be denoted as the “$d$-channel mixing”. Thus there exists an asymmetry between the mixing of the first and second families and that of the second and
third families, which in our view reflects interesting details of the underlying dynamics of flavor mixing. The heavy quark mixing is a combined effect, involving both charge $+2/3$ and charge $-1/3$ quarks, while the u- or d-channel mixing (described by the angle $\theta_u$ or $\theta_d$) proceeds solely in the charge $+2/3$ or charge $-1/3$ sector. Therefore an experimental determination of these two angles would allow to draw interesting conclusions about the amount and perhaps the underlying pattern of the u- or d-channel mixing.

e) The three angles $\theta$, $\theta_u$ and $\theta_d$ are related in a very simple way to observable quantities of $B$-meson physics. For example, $\theta$ is related to the rate of the semileptonic decay $B \to D^* l \nu_l$; $\theta_u$ is associated with the ratio of the decay rate of $B \to (\pi, \rho) l \nu_l$ to that of $B \to D^* l \nu_l$; and $\theta_d$ can be determined from the ratio of the mass difference between two $B_d$ mass eigenstates to that between two $B_s$ mass eigenstates. We find the following exact relations:

$$
\sin \theta = |V_{cb}| \sqrt{1 + \frac{|V_{ub}|^2}{|V_{cb}|^2}},
$$

and

$$
\tan \theta_u = \frac{|V_{ub}|}{|V_{cb}|},
\tan \theta_d = \frac{|V_{td}|}{|V_{ts}|}.
$$

These simple results make the parametrization (21) uniquely favorable for the study of $B$-meson physics.

By use of current data on $|V_{ub}|$ and $|V_{cb}|$, i.e., $|V_{cb}| = 0.039 \pm 0.002$ and $|V_{ub}/V_{cb}| = 0.08 \pm 0.02$ 3), we obtain $\theta_u = 4.57^\circ \pm 1.14^\circ$ and $\theta = 2.25^\circ \pm 0.12^\circ$. Taking $|V_{td}| = (8.6 \pm 2.1) \times 10^{-3}$, which was obtained from the analysis of current data on $B^0_d$-$\bar{B}^0_d$ mixing, we get $|V_{td}/V_{ts}| = 0.22 \pm 0.07$, i.e., $\theta_d = 12.7^\circ \pm 3.8^\circ$. Both the heavy quark mixing angle $\theta$ and the u-channel mixing angle $\theta_u$ are relatively small. The smallness of $\theta$ implies that Eqs. (24) and (25) are valid to a high degree of precision (of order $1 - c \approx 0.001$).

Recently a global fit of these angles was made17), with rather small uncertainties for the angles and the phase $\varphi$. One finds:

$$
\theta = (2.30 \pm 0.09)^\circ, \quad \theta_u = (4.87 \pm 0.86)^\circ, \quad \theta_d = (11.71 \pm 1.09)^\circ, \quad \varphi = (91.1 \pm 11.8)^\circ,
$$

These values are consistent with the ones given above, however, the errors are smaller.

f) According to Eq. (22), as well as Eq. (21), the phase $\varphi$ is a phase difference between the contributions to $V_{us}$ (or $V_{cd}$) from the u-channel mixing and the d-channel mixing. Therefore $\varphi$ is given by the relative phase of $D_d$ and $D_u$ in the quark mass matrices (17), if the phases of $B_u$ and $B_d$ are absent or negligible.

The phase $\varphi$ is not likely to be $0^\circ$ or $180^\circ$, according to the experimental values given above, even though the measurement of CP violation in $K^0$-$\bar{K}^0$ mixing is not taken
into account. For $\varphi = 0^\circ$, one finds $\tan \theta_C = 0.14 \pm 0.08$; and for $\varphi = 180^\circ$, one gets $\tan \theta_C = 0.30 \pm 0.08$. Both cases are barely consistent with the value of $\tan \theta_C$ obtained from experiments ($\tan \theta_C \approx |V_{us}/V_{ud}| \approx 0.226$).

g) The CP-violating phase $\varphi$ in the flavor mixing matrix $V$ can be determined from $|V_{us}| (= 0.2205 \pm 0.0018)$ through the following formula, obtained easily from Eq. (21):

$$\varphi = \arccos \left( \frac{s_u^2 c_d^2 c^2 + c_u^2 s_d^2 - |V_{us}|^2}{2 s_u c_u s_d c_d c} \right).$$  \hspace{1cm} (29)

The two-fold ambiguity associated with the value of $\varphi$, coming from $\cos \varphi = \cos(2\pi - \varphi)$, is removed if one takes $\sin \varphi > 0$ into account (this is required by current data on CP violation in $K^0$-$\bar{K}^0$ mixing (i.e., $\epsilon_K$)). More precise measurements of the angles $\theta_u$ and $\theta_d$ in the forthcoming experiments of $B$ physics will remarkably reduce the uncertainty of $\varphi$ to be determined from Eq. (29). This approach is of course complementary to the direct determination of $\varphi$ from CP asymmetries in some weak $B$-meson decays into hadronic CP eigenstates. As mentioned above, the phase $\varphi$ appears to be very close to $90^\circ$.

h) It is well-known that CP violation in the flavor mixing matrix $V$ can be described in a way which is invariant with respect to phase changes by a universal quantity $J^{18})$:

$$\text{Im} \left( V_{l\alpha} V_{l\beta}^* \right) = J \sum_{k,n=1}^{3} (\epsilon_{ijk} \epsilon_{lmn}) \, .$$  \hspace{1cm} (30)

In the parametrisation (21), $J$ reads

$$J = s_u c_u s_d c_d s^2 c \sin \varphi \, .$$  \hspace{1cm} (31)

Obviously $\varphi = 90^\circ$ leads to the maximal value of $J$. Indeed $\varphi = 90^\circ$, a particularly interesting case for CP violation, is quite consistent with current data. This possibility exists if $0.202 \leq \tan \theta_d \leq 0.222$, or $11.4^\circ \leq \theta_d \leq 12.5^\circ$. In this case the mixing term $D_d$ in Eq. (17) can be taken to be real, and the term $D_u$ to be imaginary, if $\text{Im}(B_u) = \text{Im}(B_d) = 0$ is assumed. Since in our description of the flavor mixing the complex phase $\varphi$ is related in a simple way to the phases of the quark mass terms, the case $\varphi = 90^\circ$ is especially interesting. It can hardly be an accident, and this case should be studied further. The possibility that the phase $\varphi$ describing CP violation in the standard model is given by the algebraic number $\pi/2$ should be taken seriously. It may provide a useful clue towards a deeper understanding of the origin of CP violation and of the dynamical origin of the fermion masses.

The case $\varphi = 90^\circ$ has been denoted as “maximal” CP violation$^{19})$. It implies in our framework that in the complex plane the u-channel and d-channel mixings are perpendicular to each other. In this special case (as well as $\theta \to 0$), we have

$$\tan^2 \theta_C = \frac{\tan^2 \theta_u + \tan^2 \theta_d}{1 + \tan^2 \theta_u \tan^2 \theta_d} \, .$$  \hspace{1cm} (32)
\[ S_u + S_c + S_t = 0, \tag{33} \]

where \( S_i \equiv V_{id}V_{ib}^* \) in the complex plane (see Fig. 2(a)). The inner angles of this triangle are denoted as usual:

\[
\begin{align*}
\alpha & \equiv \arg(-S_t S_u^*), \\
\beta & \equiv \arg(-S_c S_t^*), \\
\gamma & \equiv \arg(-S_u S_c^*). \tag{34}
\end{align*}
\]

In terms of the parameters \( \theta, \theta_u, \theta_d \) and \( \varphi \), we obtain

\[
\begin{align*}
\sin(2\alpha) &= \frac{2c_u c_d \sin \varphi (s_u s_d c + c_u c_d \cos \varphi)}{s_u^2 s_d^2 c^2 + c_u^2 c_d^2 + 2s_u s_d c_u c_d \cos \varphi}, \\
\sin(2\beta) &= \frac{2s_u c_d \sin \varphi (c_u s_d c - s_u c_d \cos \varphi)}{c_u^2 s_d^2 c^2 + s_u^2 c_d^2 - 2s_u c_u s_d c_d \cos \varphi}. \tag{35}
\end{align*}
\]

To an excellent degree of accuracy, one finds \( \alpha \approx \varphi \). In order to illustrate how accurate this relation is, let us input the central values of \( \theta, \theta_u \) and \( \theta_d \) (i.e., \( \theta = 2.25^\circ, \theta_u = 4.57^\circ \) and \( \theta_d = 12.7^\circ \)) to Eq. (35). Then one arrives at \( \varphi - \alpha \approx 1^\circ \) as well as \( \sin(2\alpha) \approx 0.34 \) and \( \sin(2\beta) \approx 0.65 \). It is expected that \( \sin(2\alpha) \) and \( \sin(2\beta) \) will be directly measured from the \( CP \) asymmetries in \( B_d \to \pi^+ \pi^- \) and \( B_d \to \jpsi K_S \) modes at a \( B \)-meson factory.

Note that the three sides of the unitarity triangle can be rescaled by \( |V_{cb}| \). In a very good approximation (with the relative error \( \sim 2\% \)), one arrives at

\[
|S_u| : |S_c| : |S_t| \approx s_u c_d : s_C : s_d. \tag{36}
\]

Equivalently, one can obtain

\[
s_\alpha : s_\beta : s_\gamma \approx s_C : s_u c_d : s_d, \tag{37}
\]
where \( s_\alpha \equiv \sin \alpha \), etc. The rescaled unitarity triangle is shown in Fig. 2(b). Comparing this triangle with the LQ–triangle in Fig. 1, we find that they are indeed congruent with each other to a high degree of accuracy. The congruent relation between these two triangles is particularly interesting, since the LQ–triangle is essentially a feature of the physics of the first two quark families, while the unitarity triangle is linked to all three families. In this connection it is of special interest to note that in models which specify the textures of the mass matrices the Cabibbo triangle and hence three inner angles of the unitarity triangle can be fixed by the spectrum of the light quark masses and the \( CP \)-violating phase \( \varphi \)^{19}.

j) It is worth pointing out that the u-channel and d-channel mixing angles are related to the Wolfenstein parameters\(^4\) in a simple way:

\[
\tan \theta_u = \left| \frac{V_{ub}}{V_{cb}} \right| \approx \lambda \sqrt{\rho^2 + \eta^2}
\]

\[
\tan \theta_d = \left| \frac{V_{td}}{V_{ts}} \right| \approx \lambda \sqrt{(1 - \rho)^2 + \eta^2},
\]

(38)

where \( \lambda \approx s_C \) measures the magnitude of \( V_{us} \). Note that the \( CP \)-violating parameter \( \eta \) is linked to \( \varphi \) through

\[
\sin \varphi \approx \frac{\eta}{\sqrt{\rho^2 + \eta^2}} \sqrt{(1 - \rho)^2 + \eta^2}
\]

in the lowest-order approximation. Then \( \varphi = 90^\circ \) implies \( \eta^2 \approx \rho(1 - \rho) \), on the condition \( 0 < \rho < 1 \). In this interesting case, of course, the flavor mixing matrix can fully be described in terms of only three independent parameters.

k) Compared with the standard parametrization of the flavor mixing matrix \( V \) our parametrization has an additional advantage: the renormalization-group evolution of \( V \), from the weak scale to an arbitrary high energy scale, is to a very good approximation associated only with the angle \( \theta \). This can easily be seen if one keeps the \( t \) and \( b \) Yukawa couplings only and neglects possible threshold effect in the one-loop renormalization-group equations of the Yukawa matrices\(^20\). Thus the parameters \( \theta_u, \theta_d \) and \( \varphi \) are essentially independent of the energy scale, while \( \theta \) does depend on it and will change if the underlying scale is shifted, say from the weak scale (\( \sim 10^2 \) GeV) to the grand unified theory scale (of order \( 10^{16} \) GeV). In short, the heavy quark mixing is subject to renormalization-group effects; but the u- and d-channel mixings are not, likewise the phase \( \varphi \) describing \( CP \) violation and the LQ–triangle as a whole.

We have presented a new description of the flavor mixing phenomenon, which is based on the phenomenological fact that the quark mass spectrum exhibits a clear hierarchy pattern. This leads uniquely to the interpretation of the flavor mixing in terms of a heavy quark mixing, followed by the u-channel and d-channel mixings. The complex phase \( \varphi \), describing the relative orientation of the u-channel mixing and the d-channel mixing in the complex plane, signifies \( CP \) violation, which is a phenomenon primarily linked to the
physics of the first two families. The Cabibbo angle is not a basic mixing parameter, but
given by a superposition of two terms involving the complex phase $\phi$. The experimental
data suggest that the phase $\phi$, which is directly linked to the phases of the quark mass
terms, is close to 90°. This opens the possibility to interpret $CP$ violation as a maximal
effect, in a similar way as parity violation.

Our description of flavor mixing has many clear advantages compared with other de-
scriptions. We propose that it should be used in the future description of flavor mixing
and $CP$ violation, in particular, for the studies of quark mass matrices and $B$-meson
physics.

The description of the flavor mixing phenomenon given above is of special interest if
for the u- and d-channel mixings specific quark mass textures are used.
In that case one often finds\textsuperscript{14,19} apart from small corrections

$$
\tan \theta_d = \sqrt{\frac{m_d}{m_s}},
\tan \theta_u = \sqrt{\frac{m_u}{m_c}}.
\tag{40}
$$

The experimental value for $\tan \theta_u$ given by the ratio $|V_{ub}/V_{cb}|$ is in agreement with the ob-
served value for $(m_u/m_c)^{1/2} \approx 0.07$, but the errors for both $(m_u/m_c)^{1/2}$ and $|V_{ub}/V_{cb}|$ are
the same (about 25%). Thus from the underlying texture no new information is obtained.

This is not true for the angle $\theta_d$, whose experimental value is due to a large uncertainty: $\theta_d = 12.7° \pm 3.8°$. (The analysis given in\textsuperscript{12} indicates, however, that the uncertainty for $\theta_d$
may be less). If $\theta_d$ is given indeed by $(m_d/m_s)^{1/2}$, which is known to a high accuracy, we
would know $\theta_d$ and therefore all four parameters of the CKM matrix with high precision.

The phase angle $\phi$ is very close to 90°, implying that the LQ–triangle and the unitarity
triangle are essentially rectangular triangles\textsuperscript{19}. In particular the angle $\beta$ which is likely to
be measured soon in the study of the reaction $B^0 \rightarrow J/\psi K_S^0$ is expected to be close to 20°.

Finally we should like to indicate the structure of the quark mass matrices which fol-
low if the two relations given above are fulfilled. Both for the charge 2/3 and charge
(−1/3) quarks they have the structure:

$$
M = \begin{pmatrix}
0 & A & 0 \\
A^* & B & C \\
0 & C^* & D
\end{pmatrix}
\tag{41}
$$

where $|A| \ll |B|, K \ll |D|$. As discussed previously, the texture zeros at the (1, 3) and
(3, 1)–positions can always be arranged by a suitable unitary transformation of the
quark fields. Ones this is carried out, a specific basis in flavor space is adopted. The
relations (40) follow if the (1, 1)–element vanishes in this basis. It remains to be seen
what constitutes the deeper reason for this zero, perhaps a specific reflection symmetry\textsuperscript{14})
or simple irreducible term to break the democratic symmetry among the quark flavors\textsuperscript{21}).
\(CP\)–violation results if there is a relative phase between \(A_d\) and \(A_u\). It is maximal if this
phase is 90\(^\circ\), as suggested by the preliminary experimental data\textsuperscript{22}).

It will be very interesting to see whether the angles \(\theta_d\) and \(\theta_u\) are indeed given by the
square roots of the light quark mass ration \(m_d/m_s\) and \(m_u/m_c\), which imply that the
phase \(\varphi\) is close to or exactly 90\(^\circ\). This would mean that the light quarks play the most
important rôle in the dynamics of flavor mixing and \(CP\) violation and that a small win-
dow has been opened allowing the first view across the physics landscape beyond the
mountain chain of the Standard Model.

Acknowledgements: It is my pleasure to thank Prof. A. Zichichi for the invitation to
come to Erice and for his continuous and fruitful efforts to generate a lively and creative
atmosphere at the Erice School on Subnuclear Physics.
