Abstract

Background: This study aimed to determine the effectiveness of 36 hospital learning centers for the continued education of sick children using electronic distance learning television (eDLTV), parents’ attitudes toward their child’s illnesses and education, and service satisfaction of the centers.

Methods: The sample included 4,430 children aged 4-18 years old with common illnesses, chronic illnesses and developmental disorders, as well as 4,430 parents who had taken care of the child for at least 6 months. The methods included attitude surveys, which were analyzed using chi-square tests and t-tests.

Results: The factors associated with education continuation of the children were illness types (parents were less worried about children with common illness and more concerned about education of children with chronic diseases and children with disabilities), distance from home to school, transportation type, parents' education level, marital status, and family income. About 99.8% of patients with common illnesses continued their education, followed by 99.3% of disabled children, and 95.9% of chronic patients. Satisfaction score towards the services at the learning centers were high (mean scores: 4.28 and 4.43 respectively, out of 5 = strongly satisfied).

Conclusion: After completing an education program through eDLTV at a center, a total of 97.7% of children continued their education and were highly satisfied with the service at the center. Parents had positive attitudes towards their child's illnesses and education.
Introduction

As a crucial foundation for development, education should be equally accessible to all children, regardless of differences in social or physical status. Today medical advancements have increased the survival rate of children with chronic diseases to 90%, reducing mortality rates and complications, and increasing life expectancy by as much as 20 years longer. The prevalence of children with chronic diseases differs depending on definition. A survey in the United States indicated that approximately 20% of children had chronic illnesses. In Thailand, the number is still unclear because chronic illness is defined as a long-term illness involving treatments that might affect the lifestyles of children and families. Such changes can include absence from school, which could affect learning and social activities.

The UN Convention of the Rights of the Child states that every child has the right to be protected and receive equal education. As a member of the UN, Thailand implemented a law stipulating that “education is not only limited to the classroom”. Therefore, medical institutes have merged with special education centers to establish “learning centers in the hospital” so that pediatric patients can continue to have equal access to education. Making use of information technology to support education, the project is called “The Information Technology Project under the Initiative of Her Royal Highness Princess Maha Chakri Sirindhorn”. Similar learning centers in other countries involve the coordination of multidisciplinary teams to enhance social and learning activities or sick children.

The Queen Sirikit National Institute of Child Health (QSNICH) Learning Center in Thailand has been operating for 20 years. In the past, education for sick children supported academic knowledge and daily living skills which made them feel included in society, and reflected educational and social perceptions of the related life adjustments and psychological conditions. QSNICH has previously conducted research on education for sick children, aiming to determine the effectiveness of learning centers in 36 provinces in Thailand. Hospital Learning Centers for sick children uses standardized curriculum established by Ministry of Education applicable for children at all education levels: pre-kindergarten, primary, secondary, tertiary levels, as well as vocational education. This curriculum is a collaboration between MOU partners: Ministry of Education, Ministry of Public Health and Ministry of Science and Technology.

All of the operational process needs to follow Clinical Practice Guideline (CPG) and pass an external audit from the third party to ensure that the education that is delivered to sick patients in every hospital learning center meet the standard.

With official ministry-level collaboration among various parties to obtain operational results regarding continued learning for sick children and the associated factors, QSNICH has provided a model for other hospitals across Thailand to ensure that all sick children have equal access to education.

Objectives

This study has been extended from previous research on the effectiveness of the learning center at QSNICH, which investigated the associated factors affecting further education of children with special needs. The aims of this study were to determine the effectiveness of 36 other network learning centers across Thailand for the continued education of pediatric patients, as well as the factors associated with the patients’ further education. It also evaluated parents’ attitudes toward their children’s illness and education, as well as service satisfaction of the center.

Methods

Study design

This research was conducted in a form of natural experimental study which variables are influenced by nature or factors outside of the researchers’ control. Cross-sectional design has been implemented in this study where a group of population from all the 36 learning centers in the hospitals across Thailand was selected based on the inclusion criteria set for the study: types of illnesses, patient’s and parent’s demographic information in order to measure the effectiveness of the project and to examine the factors correlating with continuing education of children under HSH project, patient’s attitudes and patient’s satisfaction towards HSH project. The study used a survey to collect information (Extended data) from January 1, 2018, to December 31, 2018.

Participants

The target population included 4,430 child patients aged 4–18 years as well as 4,430 parents who had taken care of the child for at least six months, meaning that the total study population included 8,860 individuals. The sample size calculation was based on Wayne. The total number of pediatric patients from 36 learning centers at the hospitals was 30,000 (n=30,000), and the incidence of children who went back to school was 80% (p=0.8)). The selection of a sample in this study was a voluntary response sample from all 36 learning centers in Hospitals across Thailand. That is, after the instruction was given to the participants, they were able to participate in the study voluntarily. If the number of participants were more than expected population, a random sample selection would be implemented.

The survey was conducted by the researchers after the parents gave written informed consent for their child to participate.
For children aged 4–7 years, parents were asked to participate in the survey on behalf of the child. The session was audio recorded for data analysis. In order to access the data, a permission from the Human Ethics Committee of the Ministry of Public Health that oversees all 36 network hospitals must be approved.

Eligibility criteria
Inclusion criteria: 1) Pediatric patients age between 4–18 years who are attending learning centers at the hospital; 2) Pediatric patients who have attended learning centers more than 2 times; 3) pediatric patients with chronic illnesses who are admitted at the hospital or needed consecutive follow-up.

Exclusion criteria: pediatric patients with serious illness and life-threatening conditions.

Data collection
The survey was divided into four parts: (1) demographic information of the children and parents (gender, age, cause of admission and length of stay (Table 1)), (2) information about the patient-parent relationship, and (3) satisfaction with service at the learning centers (measured using Likert scales of 1=unsatisfied, 2=poor, 3=fair, 4=satisfied, 5=very satisfied).

Statistical analysis
SAS 9.4 software was used for data management. Descriptive statistics, including percentages, means, and standard deviations, were used to analyze the population data and SAS 9.4 software was used to calculate frequency, percentage, mean, and standard deviation to measure the attitudes and satisfaction of the parents and children. Satisfaction data were divided into five levels, from strongly agree to strongly disagree, based on the statistical test results. Chi-square tests and t-tests were used to assess the variables associated with education continuance at the learning center.

Ethics statement
This study and the selection of the participating hospitals were approved by the Office for Ethics in Human Research, Ministry of Public Health, Thailand in 2018 (ref. REC.024/2561), and was conducted in accordance with the Declaration of Helsinki.

Results
Caregiver information
The patient population was classified into three groups: those with common illnesses, chronic illnesses, and developmental disorders (n=4,430). There were a total of 4,430 caregivers:

| Table 1. Demographic information about the child patients. |

CAUSES OF ADMISSION

Common diseases, n (%) 

| Respiratory system e.g. pneumonia bronchitis | 284 (16.10) | 284 (6.41) |
| Neurological disorder e.g. seizure         | 53 (3.00)   | 53 (1.20)  |
| Gastrointestinal disorders (e.g. enteritis, stomachache, vomiting) | 487 (27.61) | 487 (10.99) |
| Accident                                  | 213 (12.07) | 213 (4.81) |
82.94% were caregivers for patients with common illnesses, 82.68% chronic illnesses, and 72.34% developmental disorders. Biological parents or relatives comprised 17.07% of the common illnesses group, 17.28% chronic illnesses, and 26.95% developmental disorders; foster parents or teachers accounted for 0.06%, 0.04%, and 0.71%, respectively. Most caregivers were women (75.74%, 80.83%, and 82.62%, respectively), of Thai nationality (99.26%, 99.33%, and 99.65%, respectively), and Thai ethnicity (97%, 98.83%, and 99.65%, respectively). Other ethnicities included Akha, Lahu, and Burmese. The main religion was Buddhism (92.01%, 94.51%, and 97.87%, respectively), followed by Islam and Christianity. Most caregivers were aged 31–40 years (43.71%, 39.89%, and 34.40%, respectively), followed by those aged 41–50 years (23%, 39%, and 40%, respectively) and 21–30 (17.29%, 13.7%, and 18.86%, respectively). Most parents had completed vocational level, or high-school level education, followed by those with a primary or secondary educational level. Most parents were employed in labor (41.5%), agriculture (23.09%), and sales (11.22%). Most parents were married, separated, or divorced and had monthly household incomes of 10,000–30,000 baht, followed by 5,000–10,000 baht; only a small number had incomes of >30,000 baht or <5,000 baht.

| Table | Common illnesses | Chronic illnesses | Developmental disorders | All |
|-------|------------------|-------------------|-------------------------|-----|
| **Urinary system** (e.g. Urinary Tract Infection, acute pyelonephritis) | 128 (7.26) | 128 (2.89) | | |
| **Infection** (e.g. dengue fever, Influenza, encephalitis) | 328 (18.59) | 328 (7.40) | | |
| **Other types of illness** (e.g. fever, operation, appendicitis) | 294 (16.67) | 294 (6.64) | | |

**Chronic diseases**

- **Heart disease**: 119 (4.99), 119 (2.69)
- **Cancer**: 526 (22.06), 526 (11.87)
- **Kidney disease**: 153 (6.42), 153 (3.45)
- **Blood disorders**: 1055 (44.25), 1055 (23.81)
- **Chronic lung diseases/ pneumonitis /asthma**: 265 (11.12), 265 (5.98)
- **Ulcerative colitis/gastritis**: 29 (1.22), 29 (0.65)
- **Neurological disorder/ epilepsy / tumors**: 106 (4.45), 106 (2.39)
- **Diabetes**: 61 (2.56), 61 (1.38)
- **High blood pressure**: 7 (0.29), 7 (0.16)
- **Other, e.g. lupus, allergies, bone diseases**: 90 (3.78), 90 (2.03)

**Developmental disorders, n (%)**

- **Learning disability**: 56 (19.86), 56 (1.26)
- **Attention deficit hyperactivity disorder**: 92 (32.62), 92 (2.08)
- **Autism**: 33 (11.70), 33 (0.74)
- **Intellectual disability**: 90 (31.91), 90 (2.03)
- **Other types of developmental disorder, e.g. cerebral palsy, literacy, motion disorders**: 30 (10.64), 30 (0.68)

**Length of stay, n (%)**

- **1–5 days**: 1222 (69.27), 1225 (51.38), 235 (83.33), 2682 (60.54)
- **6–10 days**: 448 (25.40), 514 (21.56), 33 (11.70), 995 (22.46)
- **11–15 days**: 51 (2.89), 223 (9.35), 3 (1.06), 277 (6.25)
- **> 15 days**: 43 (2.44), 422 (17.70), 11 (3.90), 476 (10.74)
- **Missing data**: 0 (0.00), 0 (0.00), 0 (0.00), 0(0.00)
bath. Most families owned a house, while some rented a house or room. Only a small number lived with a relative. Most respondents lived in the northeastern part of Thailand.

Parent-child relationship
Of the 4,430 patients, 1,764 patients had common illnesses, 2,384 chronic illnesses, and 282 developmental disorders. In general, the caregivers of all three types of patients rated the following issues similarly. Regarding illness severity, 29.9% rated it at the minimum level, 33.6% moderate, and 20% somewhat high. Regarding when the child became ill, 43.8% of caregivers always informed teachers while 24.0% often did so. Approximately 35.7% were somewhat highly confident that their child could get along with their peers, while 24.0% were somewhat confident and 24% were highly confident. Likewise, 37.8% of caregivers put somewhat high effort to into helping their child, while 25.0% made a high-level effort. Approximately, 37.6% frequently explained the assignments to their child, and 27.5% always did so. About 37.6% had high confidence that the school provided appropriate study plans for their child, 25.5% were moderately confident, and 26.1% were extremely confident. About 34.6% of patients discussed what happened in school with their child, and 23.3% did so all the time. Regarding caregivers’ confidence in encouraging their child to control their emotions, 37.6% were somewhat highly confident, 23.5% moderately confident, and 19.6% extremely confident. About 84% of caregivers sent their child to school every day.

During hospitalization, 25.1% of the patients were in kindergarten, 58.7% in primary school, and 13.8% in secondary school. After discharge, 22.3% in kindergarten, 57.5% in primary school, and 15.6% in secondary school. About 20.9% of the patients lived <1 km from school, 53.4% lived 1–5 km away, and 25.3% lived the same distance as before joining the learning center. About 57.0% traveled to school by bicycle/motorcycle, 17.5% by private car, and 20.0% by public transportation; the means of transportation were mostly the same before and after being treatment at the center.

Children with common illnesses
As shown in Table 2, 28.5% of common illness patients were in kindergarten, 57.1% in primary school, and 13.2% in secondary school. After discharge, 28.0% were in kindergarten, 57.3% in primary school, and 15.6% in secondary school. About 20.9% of the patients lived <1 km from school, 53.4% lived 1–5 km away, and 25.3% lived the same distance as before joining the learning center. About 57.0% traveled to school by bicycle/motorcycle, 17.3% by private car, and 20.0% by public transportation; the means of transportation remained almost the same before and after being treatment at the center.

Children with chronic illnesses
Before entering the center, 23.3% were in kindergarten, 59.6% in primary school, and 14.9% in secondary school. After discharge, 18.5% were in kindergarten, 57.1% in primary school, and 18.0% in secondary school. About 24.3% of patients lived less than 1 km from school, 51.3% 1–5 km, and 23.7% the same distance as before entering the center. About 58.3% traveled to school by bicycle/motorcycle, 17.5% by personal car vehicle, and 18.4% by public transportation. Means of transportation were mostly the same before and after treatment.

Children with developmental disorders
Before entering the center, 19.5% of patients were in kindergarten, 61.4% in primary school, and 9.6% in secondary school. After discharge, 18.4% were in kindergarten, 62.4% in primary school, and 9.6% in secondary school. About 24.1% of the patients lived less than 1 km from school, 50.4% 1–5 km away, and 24.8 the same distance as before. About 50.4% traveled to school by bicycle/motorcycle, 18.4% by private vehicle, and 23.1% by public transportation. The means of transportation were slightly different before and after entering the center.

As shown in Table 3, satisfaction surveys were distributed to two groups of patients: those who continued their education and those who did not. Scores were classified into five ranges (1.00-1.80 = strongly disagree, 1.81-2.60 = disagree, 2.61-3.40 = uncertain, 3.41-4.20 = agree, and 4.21-5.00 = strongly agree). The average satisfaction score of the two groups was 4.21-5.00. Patients who continued their education thought that the lessons in the classroom were interesting; they scored this item higher than the other group did. Entertainment had been used to provide amusing and relaxed learning for these children. The patients who did not continue their education were those in final stage of life.

Table 4 shows the variables related to the continuation of education of children in each type of illnesses. Since gender is an uncontrolled variation, the researcher has selected the factors that are more likely to affect the continuation of children which are number of siblings and family income. After analyzed separately, the study found that, parents with more than 2 children are likely to discontinue education of the child with chronic diseases or with developmental problems. At the same time, family with monthly income lower than 5,000 baht considered to stop further education of the sick child. With economic constraints, parents may need to think about the cost-effectiveness of sending their child to school. It must be decided that delivering a normal developmental child may be more cost-effective than children with chronic illnesses or developmental delay since education cost is not the only expense under parents’ responsibility, but also healthcare cost or medication cost for the sick child. In contrast, the study found that number of siblings and hospital length of stay do not correlate with normal children to further education because normal school system allows them to go back to school after they recover.

Discussion
The 36 learning centers in this study were located in primary or secondary hospitals that had accepted patients from local hospitals in the area. Most patients had chronic illnesses, mostly related to hematology, cancer, and heart disease. This study’s results align with those of previous studies.

*Did not study = 34 cases, Study drop = 70 cases*
associated with gastroenterology, respiratory disorders, and accidents. The 282 children in the developmental disorder group had attention deficit hyperactivity disorder, intellectual disability, autism, and learning difficulties.

Compared to research conducted in 2000, the number of children with developmental disorders at the learning centers had increased. This is perhaps attributable to patients with physical and developmental disabilities now having better access to education. The average ages of patients with chronic and common illnesses, and developmental disorders were 9.65 years (7.10–12.44), 8.69 years (6.17–11.19), and 8.85 years (6.90–11.11), respectively. Children with chronic illnesses were more likely to discontinue education because of limitations imposed by their health conditions, namely, a high risk of becoming infected or receiving treatment during the academic year. In such cases, modified education plans were introduced. Distance learning, facilitated by technology, is recommended to help patients to keep up with classes, and stay in touch with friends, which would reduce awkwardness when they returned to school. Mobile education can overcome teacher-related limitations, and it has the advantage of allowing children to select lessons for themselves. Other factors that deprived children to attend school in this study were distance from home to school, type of transportation, education level of parents, marital status, and income. However, other factors such as nationality, ethnicity or religion had no relationship with the continuation of education statistically. The results of this study were different from the a previous study, travel distance and types of transportation in the city did not affect education as much transportation in the country.

Teachers’ roles must be adjusted in the assessment guidelines and they must be able to work with patients who have different physical and psychological conditions and education. Teachers should facilitate extra lessons for patients through special classes or e-learning, and help them pass their exams. International research studies have found that “bibliotherapy” is an effective method to for reducing anxiety, and developing skills related to learning, emotion regulation, and social interaction.

We found that parents perceived their child’s chronic illnesses as moderately severe to seriously severe. For children with common illnesses, parents found that these illnesses were not moderately severe. Most parents of children with chronic and common illness highly recognized the importance of social modification, they always kept the school updated and were highly confident that the school could provide an appropriate plan for their children. Parents of children with developmental disorders were moderately to highly confident that their child was able to build relationship with friends. Teaching and psychological skills of the teachers were needed because each patient had a different physical condition, education level and psychological condition. They must be able to help the patients reduce anxiety, adjust to their health condition and give appropriate advice. Learning activities could be given anywhere outside the classroom to encourage a learning atmosphere.

In this study, the satisfaction survey of children at the learning center gave a high score of 4.21-5.00 (mean = 4.26, SD = 0.65) for every dimension. The item that was rated the highest score was that the children enjoyed participating in the activities. The item with the second highest score was that there was interesting and up-to-date content (for example, EDLTV is used in teaching according to international standard of the Ministry of Education). The third highest scoring item was that the activities were appropriate for learning (mean = 4.18, SD =0.79). Satisfaction in being part of fun and appropriate activities was rated the fourth highest item, while the item with the lowest score was that there was a variety of material and adequate facilities used in the activities (mean = 4.11, SD = 0.74).

### Table 3. Mean scores and standard deviations for service satisfaction at the center from the patient satisfaction survey.

| Satisfaction                                           | Continued education | Did not continue education |
|--------------------------------------------------------|---------------------|---------------------------|
|                                                        | Mean    | SD  | Mean    | SD   |
| I am learning interesting lessons at the center        | 4.31    | 0.52| 4.48    | 0.64 |
| I enjoy learning new things at the center              | 4.32    | 0.52| 4.45    | 0.54 |
| I look forward to receiving services at the center     | 4.27    | 0.55| 4.38    | 0.61 |

The collaboration between learning centers and schools to monitor and refer patients, establishes a long-term plan and provide appropriate support help the patients a lot. The Cochrane library\(^1\) suggests promoting a law that would foster combined work by multidisciplinary teams from hospitals, families, schools, and communities. This way, services could be developed holistically\(^2\), and children would be encouraged to continue their education. Social and society family burdens would be reduced, which could achieve the objective of children growing up to be valuable assets of the country.

Socioeconomy factors were related to health and quality of life. After analyzed each group separately, the data showed significant correlations to further education: family income, number of siblings, parent's education. For example, children with developmental problems whose mothers work as housewives would go to school with them and learn child care guidelines from the teachers by helping their own child at school, and the mothers could implement this knowledge with their child at home; enabling their children to receive appropriate continuing education. In the future, there should be a public policy that supports caregivers and increases opportunities to access further education. Ministry of Education has training for mentors to take care of these children if the parents have full-time jobs.

Factors that were statistically significant were students' attendance and length of hospital stay, transportation and distance to school. For example, children with cancer who traveling by public transportation have higher risk of infection. Appropriate public transportation should be provided for sick children or special children. Children with disabilities have difficulties in transportation, public sectors should facilitate convenient commute to school, which will encourage children to return to school.

Relationships with friends and teachers were also essential to children with chronic diseases and children with common diseases more than children with developmental problems because the characteristics of children with developmental problems were taught in an individual manner. However, social skills are important to children with special needs because it will help improve life quality of these children. Therefore, this project allows these children to keep in touch with teacher and friends during hospital admissions, this encourages them to go back to school.

**Conclusion**

Even though the learning centers in hospitals has raised awareness among parents and children about the importance of education, and making parents and their child have better attitude towards education and satisfied with the services at the learning centers, the continuation of education still based on socioeconomic factors. The involvement of responsible organizations is essential in order to improve quality of life of these children. Therefore, appropriate educational management plans, youth care and education programs should be enforced in order to provide appropriate education that enables these children to achieve their full potential.

**Key messages**

- A good education system should allow all children to have equal access to education, including vulnerable children.
- Improvement in technology supports distance learning, which combines patient ‘healthcare, education, and social life’, thus enhancing learning equity, and helping them to return to a normal life after reentering society.
- The factors affecting education continuation should be recognized and considered in education planning for sick children.
- Satisfaction should include every dimension of services for quality improvement.
- The support from Special Education Act and multidisciplinary team will lead to successful hospital learning centers

**Limitations**

The study population was limited to children at 36 hospital learning centers in Thailand. Respondents from various institutes in other contexts should be included to increase diversity. Since different hospitals provide different types and level of services for patients with different needs, future studies should include learning centers in different types of hospitals throughout Thailand such as primary, secondary and tertiary care facilities.

Reviewer comment

Abstract
1. A Correct subject-verb agreement throughout the manuscript. For example, "Satisfaction score towards the services at the learning centers were high" should be "Satisfaction scores towards the services at the learning centers were high."
2. Improve clarity and conciseness. For example, "Parents were less worried about children with common illness and more concerned about education of children with chronic diseases and children with disabilities" can be revised to "Parents were less worried about children with common illnesses and more concerned about the education of children with chronic diseases and disabilities."
3. Use correct terminology consistently. For example, "About 99.8% of patients with common illnesses continued their education, followed by 99.3% of disabled children, and 95.9% of chronic patients." Consider revising to "About 99.8% of children with common illnesses continued their education, followed by 99.3% of children with disabilities, and 95.9% of children with chronic illnesses."

Introduction
1. There is inconsistency in the use of terms, such as "chronic diseases" and "chronic illnesses." Choose one term and use it consistently throughout the manuscript to avoid confusion.
2. The background lacks detailed information on how the QSNICH and other learning centers operate and the specific roles of different ministries. Provide more details about the operation of these centers, including the roles of the Ministry of Education, Ministry of Public Health, and Ministry of Science and Technology. Explain how the collaboration works and the specific contributions of each ministry.
3. There are several grammatical issues that need attention, such as subject-verb agreement and punctuation. Revise sentences for grammatical correctness.
   - "All of the operational process needs to follow Clinical Practice Guideline (CPG) and pass an external audit from the third party" should be "All operational processes need to follow Clinical
Practice Guidelines (CPG) and pass an external audit by a third party."
- Original: "Today medical advancements have increased the survival rate of children with chronic
diseases to 90%, reducing mortality rates and complications1, and increasing life expectancy by as
much as 20 years longer2."
Issue: Comma needed after "Today"; "as much as 20 years longer" is redundant.
Revision: "Today, medical advancements have increased the survival rate of children with chronic
diseases to 90%, reducing mortality rates and complications, and increasing life expectancy by up
to 20 years."
- Original: "The UN Convention of the Rights of the Child states that every child has the right to be
protected and receive equal education9."
Issue: "of" should be "on."
Revision: "The UN Convention on the Rights of the Child states that every child has the right to be
protected and receive equal education."
- Original: "Similar learning centers in other countries involve the coordination of multidisciplinary
teams to enhance social and learning activities or sick children."
Issue: "or" should be "for."
Revision: "Similar learning centers in other countries involve the coordination of multidisciplinary
teams to enhance social and learning activities for sick children."
- Original: "Hospital Learning Centers for sick children uses standardized curriculum established
by Ministry of Education applicable for children at all education levels: pre-kindergarten, primary,
secondary, tertiary levels, as well as vocational education."
Issue: "uses" should be "use"; "established by Ministry of Education" needs an article.
Revision: "Hospital Learning Centers for sick children use a standardized curriculum established by
the Ministry of Education, applicable for children at all education levels: pre-kindergarten, primary,
secondary, tertiary, and vocational education."
- Original: "This curriculum is a collaboration between MOU partners: Ministry of Education,
Ministry of Public Health and Ministry of Science and Technology."
Issue: Comma needed before "and."
Revision: "This curriculum is a collaboration between MOU partners: the Ministry of Education, the
Ministry of Public Health, and the Ministry of Science and Technology."
4. The objectives section can be made clearer and more precise. Clearly state the specific
objectives of the study in bullet points or a numbered list for better readability. For example: This
study extends previous research on the QSNICH learning center's effectiveness, focusing on
factors affecting further education for children with special needs. The aims are To determine the
effectiveness of 36 network learning centers across Thailand in providing continued education for
pediatric patients.
1. To identify factors associated with the continuation of education for pediatric patients.
2. To evaluate parents' attitudes toward their children's illnesses and education.
3. To assess service satisfaction at the learning centers.

Methods
1. Lack of clarity in the description of statistical methods. Clearly describe the statistical
methods used, including the rationale for choosing chi-square tests and t-tests. Explain how
data were managed.
2. Several grammatical errors, including subject-verb agreement and punctuation issues.
Revise sentences for grammatical correctness. Ensure subject-verb agreement, proper
punctuation, and correct use of articles as the followings:
This research was conducted as a natural experimental study where variables are influenced by nature or factors outside of the researchers' control.

Cross-sectional design was implemented in this study, selecting a group of participants from all 36 learning centers across Thailand based on the inclusion criteria set for the study: types of illnesses, patients' and parents' demographic information. The study aimed to measure the effectiveness of the project and examine factors correlating with the continuation of education for children under the HSH project, as well as patients' attitudes and satisfaction with the HSH project.

The total number of pediatric patients from the 36 learning centers was 30,000 (n=30,000), with an incidence of 80% (p=0.8) for children returning to school.

The sample selection in this study was a voluntary response sample from all 36 learning centers across hospitals in Thailand.

That is, after the instruction was given to the participants, they were able to voluntarily participate in the study.

If the number of participants exceeded expectations, a random sample selection would be implemented.

The session was audio-recorded for data analysis.

To access the data, permission from the Human Ethics Committee of the Ministry of Public Health overseeing all 36 network hospitals was required.

Pediatric patients age between 4-18 years who are attending learning centers at the
Pediatric patients aged between 4-18 years who are attending learning centers at the hospital;
Issue: "age" should be "aged."
Revision: "Pediatric patients aged between 4-18 years who are attending learning centers at the hospital;
- Original: "Pediatric patients who have attended learning centers more than 2 times;"
Issue: "more than 2 times" should be "more than twice."
Revision: "Pediatric patients who have attended learning centers more than twice;"
- Original: "pediatric patients with chronic illnesses who are admitted at the hospital or needed consecutive follow-up."
Issue: "admitted at the hospital" should be "admitted to the hospital"; "needed" should be "need."
Revision: "Pediatric patients with chronic illnesses who are admitted to the hospital or need consecutive follow-up."
- Original: "pediatric patients with serious illness and life-threatening conditions."
Issue: "serious illness" should be "serious illnesses."
Revision: "Pediatric patients with serious illnesses and life-threatening conditions."
- Original: "The survey was divided into four parts: (1) demographic information of the children and parents (gender, age, cause of admission and length of stay (Table 1)), (2) information about the patient-parent relationship, and (3) satisfaction with service at the learning centers (measured using Likert scales of 1=unsatisfied, 2=poor, 3=fair, 4=satisfied, 5=very satisfied)."
Issue: "four parts" but only lists three; misplaced parentheses.
Revision: "The survey was divided into four parts: (1) demographic information of the children and parents (gender, age, cause of admission, and length of stay; see Table 1), (2) information about the patient-parent relationship, (3) satisfaction with service at the learning centers (measured using Likert scales of 1=unsatisfied, 2=poor, 3=fair, 4=satisfied, 5=very satisfied), and (4) attitudes toward the HSH project."
- Original: "Chi-square tests and t-tests were used to assess the variables associated with education continuance at the learning center."
Issue: "education continuance" should be "continuation of education."
Revision: "Chi-square tests and t-tests were used to assess the variables associated with the continuation of education at the learning centers."

**Results**

1. The presentation of statistical data is inconsistent and sometimes unclear. Percentages are used in some places without clear context or comparison. Present statistical data in a more structured format, such as tables or bullet points, to clearly show the comparison between different groups. Ensure that all percentages are accompanied by the relevant sample size or context as the followings:
- Original: "There were a total of 4,430 caregivers: 82.94% were caregivers for patients with common illnesses, 82.68% chronic illnesses, and 72.34% developmental disorders."
Suggestion: "There were a total of 4,430 caregivers: 3,673 (82.94%) for patients with common illnesses, 3,660 (82.68%) for patients with chronic illnesses, and 3,206 (72.34%) for patients with developmental disorders."
- Inconsistent and unclear presentation of caregiver demographics. Original: "Most caregivers were women (75.74%, 80.83%, and 82.62%, respectively), of Thai nationality (99.26%, 99.33%, and 99.65%, respectively), and Thai ethnicity (97%, 98.83%, and 99.65%, respectively)."
Suggestion: "Most caregivers were women: 3,356 (75.74%) for patients with common illnesses, 3,636 (82.68%) for patients with chronic illnesses, and 3,656 (82.62%) for patients with developmental disorders. The majority were of Thai nationality: 4,396 (99.26%), 4,410 (99.33%),
and 4,414 (99.65%), respectively, of Thai ethnicity: 4,293 (97%), 4,379 (98.83%), and 4,414 (99.65%), respectively."

- Original: "About 57.0% traveled to school by bicycle/motorcycle, 17.3% by private car, and 20.0% by public transportation; the means of transportation remained almost the same before and after being treatment at the center."
Suggestion: "Approximately 2,525 (57.0%) traveled to school by bicycle/motorcycle, 766 (17.3%) by private car, and 886 (20.0%) by public transportation; the means of transportation remained almost the same before and after treatment at the center."

1. Several sentences contain grammatical errors, awkward phrasing, and inconsistencies in verb tenses. Revise sentences for grammatical correctness. Ensure subject-verb agreement, proper punctuation, and consistent use of verb tenses. For example:

Original: "Most caregivers were women (75.74%, 80.83%, and 82.62%, respectively), of Thai nationality (99.26%, 99.33%, and 99.65%, respectively), and Thai ethnicity (97%, 98.83%, and 99.65%, respectively)."

Revision: "Most caregivers were women (75.74%, 80.83%, and 82.62%, respectively), of Thai nationality (99.26%, 99.33%, and 99.65%), and of Thai ethnicity (97%, 98.83%, and 99.65%)."

Discussion

1. Several sentences contain grammatical errors, awkward phrasing, and inconsistencies in verb tenses. Revise sentences for grammatical correctness. Ensure subject-verb agreement, proper punctuation, and consistent use of verb tenses. For example:

Original: "Mobile education can overcome teacher-related limitations, and it has the advantage of allowing children to select lessons for themselves."

Revision: "Mobile education can overcome teacher-related limitations and has the advantage of allowing children to select lessons for themselves."

1. Inconsistent presentation of statistical data and lack of context for percentages. Present statistical data in a more structured format, such as tables or bullet points, to clearly show comparisons between different groups. Ensure that all percentages are accompanied by the relevant sample size or context. For example:

Original: "In this study, the satisfaction survey of children at the learning center gave a high score of 4.21-5.00 (mean = 4.26, SD = 0.65) for every dimension."

Revision: "In this study, the satisfaction survey of children at the learning center showed high scores in all dimensions, with an overall mean score of 4.26 (SD = 0.65). The highest-rated item was enjoyment of activities (mean = 4.31), followed by interest in content (mean = 4.27)."

1. Limited discussion of how the study's findings compare with existing literature, and lack of integration of previous studies' findings. More thoroughly compare and contrast the study's findings with those of previous studies. Discuss how this study supports, contradicts, or expands upon existing knowledge. For example:

Original: "This study's results align with those of previous studies 10, 11, 13, 16, 17 of tertiary hospitals."

Revision: "This study's results align with those of previous studies conducted in tertiary hospitals 10, 11, 13, 16, 17, which also found high rates of chronic illnesses related to hematology, cancer, and heart disease. However, unlike previous studies, our findings highlight an increase in developmental disorder diagnoses, suggesting improved access to education for these patients."

Is the work clearly and accurately presented and does it cite the current literature?

Yes
Is the study design appropriate and is the work technically sound?
Yes

Are sufficient details of methods and analysis provided to allow replication by others?
Yes

If applicable, is the statistical analysis and its interpretation appropriate?
Yes

Are all the source data underlying the results available to ensure full reproducibility?
Partly

Are the conclusions drawn adequately supported by the results?
Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Implementation science of maternal and child health

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

The article is about hospital learning center in Thailand. The strength of the article is the number of hospital learning centers and participants. However, there are some suggestions.

Objectives
The effectiveness of hospital learning center which the researcher would like to evaluate is not clear. What are the primary and secondary outcomes?

Methods
1. What were criteria to include the hospital learning center to the research? The author should give information of the learning center.
2. As the participant in the study was voluntary, how many children were refuse to be in the research? Did the participants represent actual population? It might be research bias if
there were a lot of children refuse to participate.

Results

1. Under the heading of parent-child relationship, the table of the content should be provided.

2. About table 3, the author mentions that patients who continued their education thought that the lessons in the classroom were interesting, they scored this item higher than the other group did. However, table 3 shows that scoring of "I am learning interesting lessons at the center" for the group of continued education was 4.31 and the group of did not continued education was 4.48. Is this corrected??

3. Table 4 is about the variables to continuation of education which is interesting part of the article. The author should mention more about the variables that were significant different between the children who continue the education and who did not rather than select a few variables. It is a good idea to separate participants into 3 groups and evaluate the variables associate with continuation of education. However, the author can provide more information about the variables which were different between children who continued to educate and who did not and then separate them into 3 groups as previously done.

Discussion

1. The last paragraph of page 9, "In this study, the satisfaction survey" should be mentioned in the result section rather than discussion section.

2. Should discuss more about the effectiveness for the learning center.

Is the work clearly and accurately presented and does it cite the current literature?

Partly

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Developmental Behavioral pediatrics

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.
This is a single-group interventional study. Here are areas for improvement:

1. The abstract and also the paper should make the design much more clear. Is this a longitudinal one-arm intervention (designed by authors) or is this a natural experiment designed by a system and the authors just conducted the evaluation?

2. The result is not just about attitudes. Many other factors such as socioeconomic status predict child educational success, but the title only mentions attitude.

3. One major problem is that all samples are analyzed together. However, some of these children have physical health problems and some have disabling developmental challenges. These two groups are qualitatively different and cannot be combined. Just controlling for this type as a nominal variable (0/1) does not solve the problem. I think at least for sensitivity analysis, all results should be replicated in a stratified fashion, separately for each of the groups mentioned.

4. SES and social determinants of health are root causes of health and well-being. The paper, however, does not mention these concepts despite that it measures them.

5. Overall, I think the data are much stronger than the discussion section. Many more areas could be discussed which are left untouched.

6. These children are educationally heterogeneous. This includes children at kindergarten to much higher levels. Progress in educational programs is highly dependable on the workload required. So, simply controlling for the educational level does not solve this problem. Overall, the high heterogeneity of the sample is a major problem here.

7. Sex/gender is beyond a control variable. Parents may differently invest in their boys and girls (gender norms). Similarly, a child may get different attention and investment depending on the number of siblings. Thus, more attention is needed on the composition of the household beyond marital status.
8. Another important area in this paper is poor eligibility. These poor selection criteria have made it very difficult to know who was in the study. I think the authors need to replicate their findings in groups of patients with more homogenous conditions.

9. More information is needed on the variation of the adherence to the curriculum across learning centers. How do various centers do their job? Was there any effect on centers?

10. Participants were nested to centers so they are not independent samples. Please discuss your solution to address this data challenge. Overall, despite the paper having great potential and focusing on a novel topic that is rarely done by others, authors could do a much better job with inclusion, statistics, and discussion.

Is the work clearly and accurately presented and does it cite the current literature?
Partly

Is the study design appropriate and is the work technically sound?
Partly

Are sufficient details of methods and analysis provided to allow replication by others?
No

If applicable, is the statistical analysis and its interpretation appropriate?
No

Are all the source data underlying the results available to ensure full reproducibility?
Partly

Are the conclusions drawn adequately supported by the results?
Partly

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: I am an expert of child development, social inequalities, and longitudinal data analysis. I also work related to chronic disease and mental health problems.

We confirm that we have read this submission and believe that we have an appropriate level of expertise to state that we do not consider it to be of an acceptable scientific standard, for reasons outlined above.

Author Response 29 Mar 2022
adisuda fuengfoo

1. This is a single-group interventional study. Here are areas for improvement: The abstract and also the paper should make the design much more clear. Is this a longitudinal one-arm intervention (designed by authors) or is this a natural experiment designed by a system and the authors just conducted the evaluation?
This research was conducted in a form of natural experimental study in which variables are influenced by nature or factors outside of the researchers’ control. A cross-sectional design has been implemented in this study where a group of the population is selected based on the inclusion criteria set for the study: types of illnesses, patient's and parent's demographic information in order to measure the effectiveness of the project and to examine the factors correlating with continuing education of children under HSH project, patient's attitudes and patient's satisfaction towards HSH project. However, a limitation of a cross-sectional study is that it is difficult to identify causal effects and only describe associations between variables.

2. The result is not just about attitudes. Many other factors such as socioeconomic status predict child educational success, but the title only mentions attitude.

Assessment of the Learning Center in Hospital Program was assessed on the function and effectiveness of children with health problems participating in the Learning Center in Hospital Program. Another angle, besides taking into account accuracy, should also consider preferences along the way. Therefore, it is assessed in various dimensions, such as assessing the perspectives of service users in terms of parental attitudes and the satisfaction of sick children participating in the Hospital Learning Center project, which is a secondary objective of this research and is discussed in the information found for the purpose.

3. One major problem is that all samples are analyzed together. However, some of these children have physical health problems and some have disabling developmental challenges. These two groups are qualitatively different and cannot be combined. Just controlling for this type as a nominal variable (0/1) does not solve the problem. I think at least for sensitivity analysis, all results should be replicated in a stratified fashion, separately for each of the groups mentioned.

The research team would like to accept and appreciate the advice that is very helpful. In the issue of data analysis should be separated into groups, diseases because each group of diseases has a different nature and affects learning. The researcher, therefore, brought this issue to further improve in the analysis of the data to separate the groups into three groups: common disease children, chronic disease children, and children with developmental problems, as shown in the table.

4. SES and social determinants of health are root causes of health and well-being. The paper, however, does not mention these concepts despite that it measures them.

Socioeconomic status is a very important part of healthcare and is the foundation for proper health management and lifestyle. It is a valuable recommendation when further analyzed separately. The disease group found that social socioeconomic status affecting admission to continuing education after discharge from the hospital was associated with all disease groups. When analyzed, it was found that there was still a relationship between chronic disease and chronic disease groups with developmental problems because it is a long continuous treatment, and with costs that depend on severity, complexity, and advances in technology, children with chronic and developmental diseases have a better
chance of living longer.

5. Overall, I think the data are much stronger than the discussion section. Many more areas could be discussed which are left untouched.

The researcher agreed and used the data for further analysis, separating the disease groups. We have added more discussion on factors that remained related to children's continued return to school when analyzing disease groups: parents' education, socioeconomic status, family income, number of siblings, etc.

6. These children are educationally heterogeneous. This includes children at kindergarten to much higher levels. Progress in educational programs is highly dependable on the workload required. So, simply controlling for the educational level does not solve this problem. Overall, the high heterogeneity of the sample is a major problem here.

We agree on the issue of diversity in the classroom as one of the limitations of education in nature experimental study. In a future study, we will include prospective follow-up studies and segmented samples for cross-sectional study to reduce such limitations.

7. Sex/gender is beyond a control variable. Parents may differently invest in their boys and girls (gender norms). Similarly, a child may get different attention and investment depending on the number of siblings. Thus, more attention is needed on the composition of the household beyond marital status.

Since gender is an uncontrolled variation, the researcher has selected the factors that are more likely to affect the continuation of children which are the number of siblings and family income. After analyzing separately, the study found that parents with more than 2 children are likely to discontinue education of the child with chronic diseases or with developmental problems. At the same time, families with a monthly income lower than 5,000 baht considered stopping further education of the sick child. With economic constraints, parents may need to think about the cost-effectiveness of sending their child to school. It must be decided that delivering a child without chronic illnesses or developmental delay may be more cost-effective than children with chronic illnesses or developmental delay since education cost is not the only expense under parents’ responsibility, but also healthcare costs or medication costs for the sick child. In contrast, the study found that the number of siblings and hospital length of stay do not correlate with children without chronic illnesses or developmental delay to further education because the normal school system allows them to go back to school after they recover.

8. Another important area in this paper is poor eligibility. These poor selection criteria have made it very difficult to know who was in the study. I think the authors need to replicate their findings in groups of patients with more homogenous conditions.

It is a valuable suggestion that gives the researcher a clearer perspective. Therefore, the researcher has divided the groups to select the pediatric patients by separate disease groups and analyze the factors affecting admission to further education in order to create
more homogeneous conditions as shown in the table.

9. More information is needed on the variation of the adherence to the curriculum across learning centers. How do various centers do their job? Was there any effect on centers?

Hospital Learning Centers for sick children use a standardized curriculum established by the Ministry of Education applicable for children at all education levels: pre-kindergarten, primary, secondary, tertiary levels, as well as vocational education. This curriculum is a collaboration between MOU partners: the Ministry of Education, Ministry of Public Health, and Ministry of Science and Technology.

All of the operational processes need to follow the Clinical Practice Guideline (CPG) and pass an external audit from a third party to ensure that the education that is delivered to sick patients in every hospital learning center meets the standard.

10. Participants were nested to centers so they are not independent samples. Please discuss your solution to address this data challenge.

The selection of a sample in this study was a voluntary response sample from all 36 learning centers in Hospitals across Thailand. That is, after the instruction was given to the participants, they were able to participate in the study voluntarily. If the number of participants was more than the expected population, a random sample selection would be implemented. In order to access the data, permission from the Human Ethics Committee of the Ministry of Public Health that oversees all 36 network hospitals must be approved.

**Competing Interests:** No competing interests were disclosed.
**Introduction part**

- For a clearer understanding, the Authors should give more information about the 36 learning centers, such as how they are settled in hospitals (place, operational time), who are teachers in the centers, how they select pediatric patients to attend the centers (by doctor referral or who else) and how they provide educational service (curriculum, activity)? And also, more information about eDLTV may help readers who are not in Thailand understand it. The Authors may add information about how the QSNICH learning center supervises the other 36 learning centers.

**Methodology**

- A flow chart that shows how 4430 participants in this study were recruited from 30,000 pediatric patients of the 36 centers could be helpful to show a clear overview of the recruitment process.

- There are 4430 data in the research rather than 8860. The author can explain that 4430 children included in the research and 4430 parents were interviewed.

- Definition for classifying common illness from chronic illness should be mentioned (depend on the type of disease or hospital day)

- The questionnaires used in the study should be defined in detail for better understanding, such as numbers of items in the satisfactory scales and how is the total score obtained, what are questions asked in the demographic data and validation process of the questionnaire.

**Results**

- The main research findings on effectiveness may not yet clear to readers. The authors may adjust or add a table that defines the effectiveness of the program. For example, in Table 3, statistical analysis of differences in satisfaction between 2 groups could add more information about effectiveness.

- In table 4, Is not clear that the heading "continue education" means continue education at a learning center or at a formal school. and also the distance from school means the formal school or learning center.

**Key messages**

- The main result of this study about effectiveness should be added as the key message.

**Is the work clearly and accurately presented and does it cite the current literature?**

Partly

**Is the study design appropriate and is the work technically sound?**

Partly

**Are sufficient details of methods and analysis provided to allow replication by others?**

Partly
If applicable, is the statistical analysis and its interpretation appropriate?
Partly

Are all the source data underlying the results available to ensure full reproducibility?
Partly

Are the conclusions drawn adequately supported by the results?
Partly

**Competing Interests:** No competing interests were disclosed.

**Reviewer Expertise:** Developmental and behavioral pediatrician

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage

For pre-submission enquiries, contact research@f1000.com
