Abstract

Background: γ-aminobutyric acid (GABA) is an important inhibitory neurotransmitter which mainly mediates its effects on neurons via ionotropic (GABAA) and metabotropic (GABAB) receptors. GABAB receptors are widely expressed in the central and the peripheral nervous system. Although there is evidence for a key function of GABAB receptors in the modulation of pain, the relative contribution of peripherally- versus centrally-expressed GABAB receptors is unclear.

Results: In order to elucidate the functional relevance of GABAB receptors expressed in peripheral nociceptive neurons in pain modulation we generated and analyzed conditional mouse mutants lacking functional GABAB(1) subunit specifically in nociceptors, preserving expression in the spinal cord and brain (SNS-GABAB(1)-/- mice). Lack of the GABAB(1) subunit precludes the assembly of functional GABAB receptor. We analyzed SNS-GABAB(1)-/- mice and their control littermates in several models of acute and neuropathic pain. Electrophysiological studies on peripheral afferents revealed higher firing frequencies in SNS-GABAB(1)-/- mice compared to corresponding control littermates. However no differences were seen in basal nociceptive sensitivity between these groups. The development of neuropathic and chronic inflammatory pain was similar across the two genotypes. The duration of nocifensive responses evoked by intraplantar formalin injection was prolonged in the SNS-GABAB(1)-/- animals as compared to their control littermates. Pharmacological experiments revealed that systemic baclofen-induced inhibition of formalin-induced nociceptive behaviors was not dependent upon GABAB(1) expression in nociceptors.

Conclusion: This study addressed contribution of GABAB receptors expressed on primary afferent nociceptive fibers to the modulation of pain. We observed that neither the development of acute and chronic pain nor the analgesic effects of a systematically-delivered GABAB agonist was significantly changed upon a specific deletion of GABAB receptors from peripheral nociceptive neurons in vivo. This lets us conclude that GABAB receptors in the peripheral nervous system play a less important role than those in the central nervous system in the regulation of pain.

Background

Metabotropic GABA receptors, namely GABA<sub>B</sub> receptors, mediate the slow and prolonged physiological effects of the inhibitory neurotransmitter, GABA. They play an important role in the modulation of synaptic transmission. Contribution of pre-as well as post-synaptic GABA<sub>B</sub> receptors in the modulation of long-term plasticity phenomena in brain regions, such as the hippocampus and amygdala, has been described [1-5]. GABA<sub>B</sub> receptors are also highly concentrated in the superficial dorsal horn, predominantly on afferent terminals of sensory neurons located in the dorsal root ganglia (DRG) [6-9]. Amongst these, small-diameter nociceptive neurons show a high density of GABA<sub>B</sub> receptor expression [7,10]. However, GABA<sub>B</sub> receptors are also expressed postsynaptically on second order neurons and as well as at motor neuron synapses [11,12]. The expression of GABA<sub>B</sub> receptor subunits is enhanced in lumbar spinal cord and dorsal root ganglion following chronic nociceptive activation in models of axotomy and chemogenic pain [13].

Multiple lines of evidence support an antinociceptive role for GABA<sub>B</sub> receptors in animal models of acute and chronic pain. Baclofen, a GABA<sub>B</sub> receptor agonist, exhibits antinociceptive effects in model of peripheral nerve injury and chronic inflammation [14]. Baclofen also attenuates pain-related behaviors evoked by the formalin injection in rats and also reduces allodynia-like behavioral symptoms in disease models of chronic pain inducing monoarthritis [15], ischemic injury to the spinal cord [16], carrageenan-produced inflammation [17] or trigeminal neuralgia [18,19]. In the view of extensive literature in animal models of acute and chronic pain, it is rather surprising that the clinical administration of GABA<sub>B</sub> receptor agonists as analgesics has been restricted to trigeminal neuralgia and post-herpetic neuralgia [20,21]. Indeed, GABA<sub>B</sub> receptor agonists display muscle relaxant properties and are rather widely used in the control of spasticity [22,23] and have been implicated in dystonia [24]. Because evoked pain behaviors in animal studies mostly rely upon a motor behavioral response, the motor deficits caused by GABA<sub>B</sub> receptor modulation occlude an unequivocal interpretation of behavioral responses. Another important caveat is that currently available GABA<sub>B</sub> ligands suffer from lack of selectivity with respect to the locus of action within the different components of the spinal sensory-motor circuit. Thus, a complete delineation of the sensory antinociceptive actions from the motor inhibitory actions of GABA<sub>B</sub> receptors is not possible using the conventional approach of ligand delivery in animals.

We reasoned that the application of genetic tools to manipulate GABA<sub>B</sub> receptor expression in a site-specific manner may enable delineating their specific role in the modulation of noceception and chronic pain. We generated mice lacking the GABA<sub>B</sub> receptors specifically in nociceptive neurons of the dorsal root ganglia. Detailed behavioral and electrophysiological analyses in the paradigms of basal and pathological nociception revealed that although GABA<sub>B</sub> receptors localized in first order nociceptive neurons have the capacity to modulate sensitization phenomena, their contribution towards the modulation of pain at the level of the whole living organism is not pronounced. Furthermore, pharmacological experiments showed that baclofen-induced antinociception is mechanistically-independent of GABA receptors in the first nociceptive neurons.

Materials and methods

Genetically-modified mice

Homozygous mice carrying the GABAB1 flox allele (GABAB<sub>B1(1)</sub> flanked by lox<sup>P</sup> sites, GABAB<sub>B1(1)</sub><sup>flox/flox</sup>) have been described previously in details [25] GABAB<sub>B1(1)</sub><sup>flox/flox</sup> mice were crossed with SNS-Cre mice [26] to obtain GABAB1-LoxPSNS-Cre+ mice (referred to as SNS-GABAB<sub>B1(-/-)</sub> mice in this manuscript) and GABAB<sub>B1(-/-)</sub><sub>fl/fl</sub> mice (control littermates). Genotyping was done on mouse genomic tail DNA using primers: for sense strand 5'-ATCTCTTCCITGGCGTTCGTTCCTGCCTGCG-3' and for anti-sense 5'-GGTATTGATGATCGGAATTCCTC-3' to detect SNS-Cre transgene expression.

Aldrich) according to standard protocols [27]. For generation of riboprobes, 1.7 kb-long GABA<sub>B1</sub>-specific probes were generated and in situ hybridisation using nonradioactive Dig-UTP-labelled antisense and sense probes was performed on cryostat sections of DRG (16 μm) as described in details previously [28].

In Situ Hybridisation

For generation of riboprobes, 1.7 kb-long GABA<sub>B1</sub>-specific probes were generated and in situ hybridisation using nonradioactive Dig-UTP-labelled antisense and sense probes was performed on cryostat sections of DRG (16 μm) as described in details previously [28].

Nociceptive tests and mouse models of pain

All animal use procedures were in accordance with ethical guidelines imposed by the local governing body (Regierungspräsidium Karlsruhe, Germany). All behavioral measurements were done in awake, unrestrained, age-matched, female or male mice which were more than 3 months of age. Complete Freund’s adjuvant (CFA, Sigma
A total of 19 mice (10 GABA<sub>B(1)</sub><sub>−/−</sub> and 9 SNS-GABA<sub>B(1)</sub><sub>−/−</sub>) were used in the electrophysiological investigations. An in vitro skin nerve preparation was used to study the properties of mechanosensitive C- and Aδ-afferent fibers which innervate the skin in the inflamed area. Experiments were performed on the dissected skin of control animals and animals sacrificed 4 hours following CFA inoculation into the hindpaw (30 μl). Animals were killed by CO<sub>2</sub> inhalation, the saphenous nerve was dissected with the skin of the dorsal hind-paw attached and mounted in an organ bath "inside-up" to expose the dermis. The preparation was perfused with an oxygen-saturated modified synthetic interstitial fluid solution containing (in mM) 123 NaCl, 3.5 KCl, 0.7 MgSO<sub>4</sub>, 1.5 NaH<sub>2</sub>PO<sub>4</sub>, 1.7 NaH<sub>2</sub>PO<sub>4</sub>, 2.0 CaCl<sub>2</sub>, 9.5 sodium gluconate, 5.5 glucose, 7.5 sucrose, 10 Hepes at temperature of 32 ± 1°C and pH 7.4 ± 0.05. Fine filaments were teased from the desheathed nerve placed in separate chamber and placed on a recording electrode.

Nerve fibers were classified according to their conduction velocities, von Frey thresholds, and firing properties. Electrical stimulation of the nerve fiber was employed to calculate conduction velocities of individual nerve fibers. Fibers which conducted < 1 m/s and fibers conducting between 1-10 m/s were considered to be unmyelinated C-fibers and myelinated Aδ-fibers, respectively. Some of the fibers of the velocities around 1 m/s where not included into the analyses if further detailed classification according to the firing properties and threshold was not possible.

Once the receptive field was identified using the glass rod a computer-controlled linear stepping motor (Nanomotor Kleindiek Nanotechnik) [33] was used to apply standardized mechanical stimuli. Each fiber was tested with series of displacement mechanical stimuli ranging from 6 to 384 μm for both control and CFA injected animals. Electrophysiological data were collected with Powerlab 4.0 system and analyzed off-line with the spike histogram extension of the software.

**Data analysis & statistics**

All data are presented as mean ± standard error of the mean (S.E.M.). Analysis of variance (ANOVA) for random measures was performed followed by post-hoc Fisher's test to determine statistically significant differences. p < 0.05 was considered significant.

**Results**

**Conditional and specific deletion of GABA<sub>B(1)</sub> in nociceptors**

We utilized the Cre-loxP system to generate mice conditionally lacking GABA<sub>B</sub> receptors specifically in primary nociceptors. We have previously described the generation of BAC transgenic mice expressing the Cre-recombinase under the influence of promoter elements of the mouse Scn10a gene encoding the Na<sub>1.8</sub> sodium channel. This line enables gene deletion specifically in c- and Aδ-nociceptors in the dorsal root ganglia while preserving gene expression in the central nervous system and other tissues [26,34]. Mice carrying floxed GABAB1 allele [25] were crossed with SNS-Cre+ mice to generate homozygous mice in which the Cre-mediated excision of GABA<sub>B(1)</sub> exon will assure the absence of GABAB1 gene product in pre-synaptic order nociceptive neurons and their peripheral and central terminals. These include all of the known C-terminal variants of GABA<sub>B(1)</sub> such as GABA<sub>B(1a)</sub>, which contributes largely to the GABA<sub>B(1)</sub> expression in nociceptors, GABA<sub>B(1b)</sub> and the additional, newly described GABA<sub>B(1e)</sub> that can mediate dominant-negative effects on...
GABA$_B_1$ receptor heteromerization and is indeed expressed in pain pathways [35]. Based on our understanding of GABA$_B_1$ receptor heteromerization, lack of the GABA$_B_1$ subunit precludes the assembly of functional GABA$_B_1$ receptor [28,36-38]. Previous studies have shown that the deletion of GABA$_B_1$ subunit is sufficient to cause the loss of pre- and post-synaptic GABA$_B_1$ responses [25,39].

Western blot analysis showed that in SNS-GABA$_B_1^{-/-}$ mice expression of GABA$_B_1$ protein in the dorsal root ganglia (DRG) is largely reduced, whereas expression in the brain and spinal cord remains unchanged (Fig. 1A and 1B). In situ mRNA hybridisation using GABA$_B_1$-specific riboprobes revealed that only a small proportion of neurons expressing mRNA for GABA$_B_1$ belongs to the group of large diameter neurons. A majority of GABA$_B_1$ expressing DRG neurons are small-diameter neurons. SNS-GABA$_B_1^{-/-}$ mice showed a selective deletion of GABA$_B_1$ in small diameter neurons of the DRG whereas expression in large-diameter neurons was preserved (Fig. 1C).

**Electrophysiological analyses of peripheral nerve activity in SNS-GABA$_B_1^{-/-}$ mice**

To clarify the specific contribution of GABA$_B_1$ receptors on peripheral terminals, we performed electrophysiological recordings on peripheral polymodal C-fiber nociceptors and A$\delta$ nociceptors, which were identified on the basis of stimulation and conduction properties in a hindpaw skin-nerve preparation [33]. The skin was dissected from both genotypes from either naive mice or 4 hours after injection of 30 $\mu$l CFA into the hindpaw.

Recordings were made from C- and A$\delta$-fibers because these neurons are targeted by the SNS-Cre-mediated deletion of GABA$_B_1$. Stimulus-response functions of C-fibers from naive SNS-GABA$_B_1^{-/-}$ mice and GABA$_B_1^{fl/fl}$ mice demonstrated no significant changes between the responsiveness of this population to mechanical stimulation (Fig. 2A). At 4 h following CFA-induced hind paw inflammation, the excitability of mechanoreceptive C-fibers increased significantly in GABA$_B_1^{fl/fl}$ mice (Fig. 2B; p <

**Conditional deletion of GABA$_B_1$ receptor in sensory neuron specific GABAB1 knockout mice (SNS-GABA$_B_1^{-/-}$).** (A) Western blot analysis of dorsal root ganglion (DRG), spinal cord and brain of GABA$_B_1^{fl/fl}$ and SNS-GABA$_B_1^{-/-}$ using anti-GABA$_B_1$ antibody. Equal loading of samples was controlled via analysis of tubulin expression. (B) Quantitative analysis of western blot experiments. Shown are ratios of signal intensity for GABA$_B_1$ normalized to signal intensity of tubulin expression (n = 3; p < 0.05; ANOVA). (C) mRNA in situ hybridization for expression of GABAB1 in DRG sections from GABA$_B_1^{fl/fl}$ and SNS-GABA$_B_1^{-/-}$. Antisense mRNA riboprobes showed loss of signal in small-diameter DRG neurons in SNS-GABA$_B_1^{-/-}$ in comparison to their GABA$_B_1^{fl/fl}$ littermates, whereas expression was retained in large-diameter cells.
Electrophysiological analysis of excitability of peripheral nociceptive fibers in GABA\(_{B1}\)\(^{fl/fl}\) and SNS-GABA\(_{B1}\)\(^{-/-}\) mice in the skin nerve preparation. Shown are electrophysiological recordings of spike rates evoked by application of pressure via a nanomotor (expressed in terms of displacement) from c-mechanoceptors (C-fibers, panel A, B and C) and A\(\delta\)-type of mechanoceptors (panel D, E and F) in the skin-nerve preparation derived from the paws of GABA\(_{B1}\)\(^{fl/fl}\) and SNS-GABA\(_{B1}\)\(^{-/-}\) mice. Panel A and D represent analyses in naive GABA\(_{B1}\)\(^{fl/fl}\) and SNS-GABA\(_{B1}\)\(^{-/-}\). Panels B and E represent analyses in GABA\(_{B1}\)\(^{fl/fl}\) mice at 4 h following CFA-induced hindpaw inflammation. Insets show the magnification of the firing properties for displacements from 6 to 48 \(\mu\)m. Panel C and E represent analyses in SNS-GABA\(_{B1}\)\(^{-/-}\) mice at 4 h following CFA-induced hindpaw inflammation. Representative traces of firing properties of C-fibers and A\(\delta\)-mechanoceptors for nanomotor displacement of 48 \(\mu\)m are shown below the quantitative summaries. * indicates significant statistical difference (p < 0.05; ANOVA followed by post-hoc Fisher’s test). n represents the number of fiber type for each tested animal group.
0.005, ANOVA followed by posthoc Fisher’s test; typical examples of traces are shown below the quantitative summary in Fig. 2B). Mechanoreceptive C-fibers of SNS-GABA_B(1)/- mice also demonstrated increased excitability following CFA-induced inflammation; however, statistical significance was only reached at higher forces of mechanical stimulation. Surprisingly, analysis of the basal activity of mechanoreceptive AM-fibers (Aδ-fibers) revealed that the basal excitability is significantly increased in mice lacking GABA_B(1) in peripheral nociceptors (Fig. 2D) whereas GABA_B(1)/fl/fl mice demonstrated strong hyperexcitability to the entire range of intensities of mechanical stimuli employed following CFA-induced inflammation (Fig. 2E). Aδ-fibers in SNS-GABA_B(1)/- mice failed to demonstrate any further increases in excitability following CFA (Fig. 2F). The magnitude of responses shown by SNS-GABA_B(1)/- mice to various mechanical forces in the naive state was equivalent to those shown by the GABA_B(1)/fl/fl mice in the CFA-induced sensitized state and no further sensitization was then seen in SNS-GABA_B(1)/- mice following CFA-induced inflammation.

Development of acute nociceptive hypersensitivity and its pharmacological modulation by baclofen
To determine how GABA_B receptor affects behavioral correlates of rapid sensitization in pain pathways, we performed the plantar formalin test on SNS-GABA_B(1)/- mutant mice and their wild-type controls [32]. Intraplantar injection of formalin in rodents evokes nocifensive behaviors such as licking, shaking, and lifting of the injected paw in a biphasic manner. Phase I of the formalin response (0–10 min after injection) is caused by persistent activation and acute sensitization of nociceptors, whereas the phase II response (10–60 min after injection) result from continual activation of nociceptors and a sensitization of central synapses via mechanisms which are triggered by repetitive stimulation during the first phase [32]. GABA_B(1) mutant mice failed to reveal changes in the total cumulative duration of phase I and phase II responses to formalin injection (1%, 20 μl) (Fig. 3B). However, the latter part of the phase II formalin response (so called phase IIb, [40]) was significantly prolonged in SNS-GABA_B(1)/- (n = 5) when compared to GABA_B(1)/fl/fl animals (n = 5) (Fig. 3A).

Previous studies on formalin-induced nocifensive behavior showed that intraperitoneal or intrathecal injection of GABA-B receptor agonist, baclofen induces antinociception in both phases of the formalin test [41,42]. Consistent with previous studies, baclofen (2 mg/kg of body weight), administered intraperitoneally 30 min prior to the injection of formalin showed antinociceptive effect on phase I and II (Fig. 3B, C; p < 0.05) behavior. However, baclofen was equally efficient in depressing nociceptive behavior on SNS-GABA_B(1)/- (n = 5) and GABA_B(1)/fl/fl (n = 5) mice (Fig. 3B, C; p < 0.05) suggesting that the effect of baclofen is independent on expression of GABA_B receptors in peripheral nervous system.

Development of chronic inflammatory pain in SNS-GABA_B(1)/- mice
Development of somatic inflammatory pain and hyperalgesia was assessed in GABA_B(1)/fl/fl mice and SNS-GABA_B(1)/- mice at 12 h, 1, 2, 4, 6 and 8 days following unilateral hindpaw inflammation induced by intraplantar injection of complete Freud’s adjuvant (CFA; 20 μl). In CFA-injected animals paw withdrawal latency (PWL) to noxious radiant heat decreased significantly for up to 4 days (Fig. 4A). CFA-induced thermal hyperalgesia was comparable in SNS-GABA_B(1)/- (n = 6) and GABA_B(1)/fl/fl (n = 6) mice (Fig. 4B). Magnitudes of mechanical hyperalgesia that developed after CFA injection was tested using von Frey filaments on SNS-GABA_B(1)/- mice, and their respective control littermates (Fig. 4C–F). Upon CFA injection, no significant variance in the magnitudes of both allodynia (defined as responses to 0.16-0.4 g force) as well as mechanical hyperalgesia (defined as responses to 0.6 - 4 g force) was observed in SNS-GABA_B(1)/- (n = 6) mice compared to GABA_B(1)/fl/fl mice (n = 6) (Fig. 4C-E). No significant difference in the relative drop in response thresholds that is defined as minimum force required to elicit 40% response frequency over the basal state was observed between genotypes (Fig. 4F). These results imply that a loss of GABA_B receptors in nociceptive DRG neurons does not produce a major effect on nociceptive behavior and is not involved in the modulation of chronic inflammatory pain.

Development of neurogenic pain in SNS-GABA_B(1)/+ mice
To assess whether peripheral GABA_B receptors play a role in nociceptive hypersensitivity which develops following a peripheral nerve lesion, we employed the spared nerve injury model (SNI) of neuropathic pain [30]. At any of the time points studied following injury (3, 7, 9, 16 and 23 days), no differences were found with respect to hyperalgesia and allodynia between SNS-GABA_B(1)/- mice and GABA_B(1)/fl/fl mice. Following SNI, profound mechanical allodynia was recorded by measuring paw withdrawal latency using a dynamic aesthesiometer. Mechanical allodynia developed to a similar extent in SNS-GABA_B(1)/- and GABA_B(1)/fl/fl mice (Fig. 5A). Thermal hyperalgesia to heat developed to a comparable extent in SNS-GABA_B(1)/- mice and GABA_B(1)/fl/fl mice (Fig. 5B). Similarly, cold allodynia (responses to 5°C) developed equally in SNS-GABA_B(1)/- mice and GABA_B(1)/fl/fl mice following SNI (Fig. 5C, D). From these data, we infer that GABA_B receptors expressed by Aδ- and C-nociceptive peripheral neurons are not involved in regulation of neuropathic pain.
Formalin-induced nociception and its modulation by GABAB(1) agonist, baclofen, in GABAB(1)fl/fl and SNS-GABAB(1)-/- mice.

Figure 3

Formalin-induced nociception and its modulation by GABAB(1) agonist, baclofen, in GABAB(1)fl/fl and SNS-GABAB(1)-/- mice. (A) Time course of nocifensive behavior after the injection of 1% formalin into the hindpaw in SNS-GABAB(1)-/- mice and their control littermates. (B) Cumulative analysis of phase I (0-10 min) and phase II (10-60 min) of the formalin response shows no significant differences in both genotypes, SNS-GABAB(1)-/- and GABAB(1)fl/fl mice. Intraperitoneal injection of baclofen (2 mg/kg body weight) applied 30 minutes before intraplantar injection of formalin caused a reduction in both phases in GABAB(1)fl/fl as well as SNS-GABAB(1)-/- mice. (C) baclofen-induced modulation of the time course of the formalin responses foregoing by intraperitoneal injection of baclofen in GABAB(1)fl/fl and SNS-GABAB(1)-/-. PBS was injected in the control group. * indicates significant statistical difference (p < 0.05; ANOVA followed by post-hoc Fisher’s test).
Figure 4
Behavior analysis of GABA_{B(1)}^{fl/fl} and SNS-GABA_{B(1)}^{-/-} mice in the CFA model of inflammatory pain. (A) Changes in paw withdrawal latency (in s) in response to noxious heat 12 hours and 1, 2, 4, 6 and 8 days following unilateral intraplantar injection of CFA. (B) Thermal hyperalgesia (changes in latency of paw withdrawal in response to noxious heat applied to the hindpaw plantar surface either before (basal) or at 12 h, and 1, 2, 4, 6 and 8 days) following unilateral intraplantar injection of CFA. Y axes represent the percent difference in paw withdrawal latency between the injected and uninjected paws calculated as (injected paw - uninjected paw) × 100/uninjected paw (negative values therefore indicate hyperalgesia). Comparison of response frequency to von Frey hairs in GABA_{B(1)}^{fl/fl} (n = 6) and SNS-GABA_{B(1)}^{-/-} (n = 6) mice prior to (C), 1 days (D) and 6 days (E) following intraplantar injection of CFA. (F) Summary of threshold (defined as a force eliciting a response frequency of at least 40%) prior to and at 12 hours and 1, 2, 4, 6 and 8 days following intraplantar injection of CFA.
Discussion
A large body of morphological, electrophysiological, behavioral, and pharmacological studies have implicated GABA_B receptors in the control of pain. However, owing to the broad expression of GABA_B receptors throughout the nervous system, spatially and temporally restricted manipulation of GABA_B receptor expression is needed to elucidate their role at different anatomical sites along the pain pathway. In this study, we generated mice lacking GABA_B(1) receptor specifically in the peripheral arm of the nociceptive pathway. These mice are well-suited for elucidating the relevance of GABA_B receptor-mediated presynaptic inhibition of neurotransmitter release from nociceptor terminals as well as a putative role for GABA_B receptors in peripheral nociceptive terminals in physiological and pathophysiological states. We analyzed mice with respect to the excitability of nociceptors and their manifestations in several models of pain, including unilateral hindpaw inflammation, chemogenic activation of nociceptors and peripheral neuropathy. Surprisingly, our detailed analyses revealed very few phenotypic differences between mice lacking GABA_B receptors in nociceptors and control mice. Briefly, our main findings were: 1. Chemical pain evoked by formalin and early nociceptive hypersensitivity were slightly prolonged in SNS-GABA_B(1)-/- mice. 2. The magnitude and duration of chronic inflammatory pain and neuropathic pain was comparable between SNS-GABA_B(1)-/- mice and control littermates. 3. Electrophysiological analyses of nociceptor activity revealed a higher basal excitability in Aδ-mechanoceptors in SNS-GABA_B(1)-/- mice; however, this did not translate into clear functional changes with respect to nociceptive behavior.

Our findings are surprising in the view of previous studies reporting GABA_B receptor expression in primary afferent terminals [6-9] as well as functional studies which show that GABA_B receptor activation on primary afferent terminals in the spinal cord reduces neurotransmitter release [43-45]. Although it is clear that GABA_B receptors are densely expressed in peripheral nociceptive neurons, the literature on the regulation of GABA_B receptor expression in pathological pain states is somewhat mixed. For example, some studies reported an increase in GABA_B receptor expression in the spinal dorsal horn and peripheral nociceptors in inflammatory pain states [13]. In contrast, Engle et al. [46] found that spinal nerve ligation does not alter the expression of GABA_B receptors in the spinal cord and dorsal root ganglia of rats and also does not lead to changes in GABA_B receptor binding affinity in inflammatory and neuropathic states. Furthermore, findings in a model of diabetic neuropathy suggest reduced function of presynaptic GABA_B receptors at primary afferent terminals, but not those on GABAergic and glycineretic interneurons, in the spinal cord [45]. Interestingly, a series of experiments with novel ligands at GABA_B receptors have also suggested a functional contribution of GABA_B(1) expressed in peripheral nociceptive neurons; e.g. α conotoxins and Rg1A peptides derived from the venom of marine Conus snails, which are currently in development for the treatment of neuropathic pain, have been shown to inhibit native calcium channel currents by the virtue of activation of GABA_B receptors in first order neurons [47]. Thus, considerable support implicates a role for GABA_B receptors expressed in peripheral nociceptive neurons in the endogenous modulation of nociception and pathological pain.

In this study, we deleted the primary ligand-binding subunit of metabotropic GABA receptors, GABA_B(1); specifically in peripheral nociceptive neurons leaving their expression in the spinal cord and brain intact. Numerous studies in cell lines as well as native tissues have demonstrated that a loss of GABA_B(1) leads to a complete lack of ligand binding and a total loss of function of native GABA_B receptors [28,36-38]. Therefore, based upon our findings, we infer that a conditional loss of GABA_B receptor function in peripheral nociceptive neurons in vivo does not lead to significant changes in nociception and the development of pathological pain.

It is interesting to note that we have found a phenotype in firing properties of Aδ peripheral afferents, but not in C-afferents in SNS-GABA_B(1)-/- mice compared to GABA_B(1)fl/fl. This might result from higher expression of GABA_B(1) in Aδ- as compared to C-fibers. As noted previously GABA_B receptor mRNA has been shown to be expressed in all DRG neurons [7]. However, studies on differential expression of the protein in different types of DRG neuron are lacking due to antibody specificity issues. Other possible explanation of the phenotype would be a more important role for GABA_B(1) in Aδ-fibers in comparison to C-fibers. This hypothesis is supported by work of Sengupta et al., who observed a more prominent blockade of Aδ-fiber, than C-afferent fiber, activity upon application of systemic baclofen in pelvic nerve afferent fibers responding to iso-baric colorectal distension [48].

It cannot be ruled out that compensatory changes, such as an increase in inhibition via other inhibitory transmitters and receptors, come into place to reinstate inhibition in pathological states. However, this is unlikely given that loss of GABA_B(1) beginning at very early developmental stages, such as in classical knockout mice, does not lead to compensation of GABAmediated inhibition with respect to pain; classical GABA_B(1) knockout mice demonstrate a prominent hyperalgesic phenotype [39]. Analyses in classical GABA_B(1) knockout mice have confirmed that a loss of the GABA_B(1) subunit is paralleled by a loss of all biochemical and electrophysiological GABA_B(1) responses
Figure 5
Analysis of GABA<sub>B(1)</sub><sup>fl/fl</sup> and SNS-GABA<sub>B(1)</sub><sup>-/-</sup> in the Spared nerve injury model for neuropathic pain. (A) Latency of paw withdrawal to dynamic von Frey stimulation in GABA<sub>B(1)</sub><sup>fl/fl</sup> and SNS-GABA<sub>B(1)</sub><sup>-/-</sup> mice before and 3,7,9,16 and 23 days following spared nerve injury (SNI). (B) Latency of thermal responses via hot plate latency test (52°C) (C) Number of reactions to a 5°C cold stimulus (flinching, licking, jumping, and shaking) during an observation period of 90 seconds on a cold plate. (D) Response to plantar application of acetone in GABA<sub>B(1)</sub><sup>fl/fl</sup> and SNS-GABA<sub>B(1)</sub><sup>-/-</sup>. All data points represent mean ± SEM. Statistical significance was not reached between mice of the two genotypes (ANOVA).

[25,39,49], demonstrating that GABA<sub>B(1)</sub> is an essential component of pre- and postsynaptic GABA<sub>B</sub> receptors. Directly comparing the phenotypes of global GABA<sub>B(1)</sub> receptor knockout mice and nociceptor-specific GABA<sub>B(1)</sub> knockout mice therefore leads to the inference that although GABA<sub>B</sub> receptors in the nervous system are important in the control of pain, these functions are likely mediated by receptors expressed in the central nervous system rather than those expressed in peripheral nociceptive neurons. However, it deserves to be noted that classically also activated by the glutamatergic inputs coming in to the spinal cord are somewhat tampered by the consequential reduction of GABAergic and glycinergic synaptic transmission onto substantia gelatinosa neurons, which are typically also activated by the glutamatergic inputs coming in via peripheral afferents [54].

Interestingly, we have found a slight phenotype in the second phase of formalin response in SNS-GABA<sub>B(1)</sub><sup>-/-</sup> compared to GABA<sub>B(1)</sub><sup>fl/fl</sup> mice. There is evidence that the second phase of the formalin response depends not only on central, spinal mechanisms but also on the neural activity generated during the first phase and continuing firing activity during the second phase [51]. Therefore, the phenotype in phase IIb of the formalin response could be caused by exaggerated activation of primary afferents due to the lack of GABA<sub>B</sub> mediated inhibition in the first phase of the formalin test.

Experimental studies with the classical GABA<sub>B</sub> receptor agonist, baclofen, have implicated a therapeutic role for GABA<sub>B</sub> receptors in the inhibition of nociceptive hypersensitivity. However, baclofen has only found limited clinical utility in the treatment of pain. We found that systematically administered baclofen can reduce nociceptive hypersensitivity, e.g. evoked by formalin, consistent with previous reports [42,43,52]. However, analysis of nociceptor-specific GABA<sub>B(1)</sub> receptor mutants revealed that this anti-nociceptive activity of baclofen occurs independently of GABA<sub>B(1)</sub> expression in peripheral nociceptive neurons. Indeed, there is considerable evidence supporting a spinal action of baclofen in inhibiting pain; in particular, administration of baclofen attenuates mechanical allodynia in a rat spinal cord injury model, whereas a GABA<sub>B</sub> receptor antagonist, phaclofen, shows opposite effects [53]. Furthermore, GABA<sub>B</sub> receptors expressed in dorsal horn neurons have been shown to participate in the modulation of secondary hyperalgesia in monoarthritic rats, which is reduced by intrathecal injection of baclofen [16]. However, some studies have also suggested a presynaptic locus of action of baclofen. For example, electrophysiological studies have suggested inhibition of neurotransmitter release from presynaptic terminals via baclofen-mediated activation of GABA<sub>B</sub> receptors [43,45]. However, the consequences of baclofen-induced inhibition of presynaptic neurotransmitter release from nociceptive afferents in the spinal cord are somewhat tampered by the consequential reduction of GABAergic and glycinergic synaptic transmission onto substantia gelatinosa neurons, which are typically also activated by the glutamatergic inputs coming in via peripheral afferents [54].

Indeed, GABA<sub>B</sub> receptors are also widely distributed in a variety of brain regions which play an important role in the modulation of pain, e.g. the rostral agranular insular cortex, a cortical area which is constantly activated by painful stimuli [55]. Furthermore, it has been shown that a local increase of GABA<sub>B</sub> concentrations in higher brain centres results in lasting bilateral analgesia [56]. Thus, the locus of baclofen action remains unclear.

Our analyses suggest that baclofen-induced inhibition of anti-nociception, particularly at doses which do not cause motor impairment, is not mediated by GABA<sub>B</sub> receptors on presynaptic nerve terminals. A detailed analysis of
baclofen-induced anti-nociception is considerably hindered by the marked motor impairment caused by baclofen at higher doses. We observed that intraplantar injection of baclofen in the hind paw did not lead to anti-nociception at low doses (data not shown); doses which evoked anti-nociception upon intraplantar administration were accompanied by a marked impairment of motor function and paralysis. Based upon these pieces of evidence, we conclude that peripheral nociceptive neurons are not the primary locus of baclofen action in the modulation of pain.

Conclusion
In summary, this study clarifies a long-standing question in the field of GABAergic modulation of nociception, namely the contribution of presynaptic GABAB receptors in primary afferent nociceptive neurons. The use of genetic tools to specifically delete GABAB receptors in DRG neurons, while leaving their expression in the spinal cord and brain intact, revealed that GABAB receptors in primary nociceptive neurons do not play a major role in the modulation of pain. Furthermore, our results suggest that anti-nociceptive effects evoked by GABAB receptor agonists are not mediated by receptors in peripheral nociceptive neurons but by receptors in the central nervous system. Thus, our results suggest that it would be advantageous to focus on the central nervous system when harnessing the GABAB receptor system for pain management.

List of abbreviations used
CFA: complete Freund's adjuvant; DRG: dorsal root ganglia; GABA: γ-aminobutyric acid; PBS: phosphate buffered saline; PWL: paw withdrawal latency; SNI: spared nerve injury.

Competing interests
The authors declare that they have no competing interests.

Authors' contributions
VG performed a large portion of the experiments and analyzed data; NA, IT and SB performed experiments; BB provided the GABA(1)fl511/fl511 mice; RK designed and analyzed data; NA, IT and SB performed experiments; BB performed a large portion of the experiments and analysis were accompanied by a marked impairment of motor function and paralysis. Based upon these pieces of evidence, we conclude that peripheral nociceptive neurons are not the primary locus of baclofen action in the modulation of pain.
