Abstract

We answer an open problem in [1] by showing that it is consistent that there is a strongly ℵ₁-free ℵ₁-coseparable group of cardinality ℵ₁ which is not ℵ₁-separable.

0 INTRODUCTION

An abelian group A is called a Whitehead group, or W-group for short, if Ext(A, Z) = 0. For historical reasons, A is called an ℵ₁-coseparable group if Ext(A, Z(ω)) = 0, but for convenience we shall use non-standard terminology and say A is a W_ω-group when A is ℵ₁-coseparable. Obviously a W_ω-group is a W-group. In 1973–75, the second author proved that it is consistent with ZFC + GCH that every W-group is free and consistent with ZFC that there are non-free W_ω-groups of cardinality ℵ₁ ([8], [9]); he later showed that it is consistent with ZFC + GCH that there are non-free W_ω-groups of cardinality ℵ₁ ([10], [11]). Before 1973 it was known (in ZFC) that every W-group is ℵ₁-free, separable, and slender, and assuming CH, every W-group is strongly ℵ₁-free. (See, for example, [3, pp. 178–180].) These turned out, by the results of the second author, to be essentially all that could be proved without additional set-theoretic hypotheses.

However, new questions of what could be proved in ZFC arose, inspired by the consistency results and their proofs. One of the most intriguing was:

(0.1) Does every strongly ℵ₁-free W_ω-group of cardinality ℵ₁ satisfy the stronger property that it is ℵ₁-separable?

(See [4, p. 454, Problem 5]). As we shall explain below, not only was the answer to this question affirmative in every known model of ZFC, but the nature of the known constructions of non-free Whitehead groups was such as to lead to the suspicion that the answer might be affirmative (provably in ZFC). However, in this paper we show that it is consistent that the answer is negative.

∗Thanks to Rutgers University for its support of this research through its funding of the authors’ visits to Rutgers.

First we recall the key definitions. An abelian group $A$ is $\aleph_1$-free if every countable subgroup of $A$ is free; $A$ is strongly $\aleph_1$-free if every countable subset is contained in a countable free subgroup $B$ such that $A/B$ is $\aleph_1$-free. $A$ is $\aleph_1$-separable if every countable subgroup is contained in a countable free subgroup $B$ which is a direct summand of $A$; so an $\aleph_1$-separable group is strongly $\aleph_1$-free. It is a consequence of CH (or even of $2^{\aleph_0} < 2^{\aleph_1}$) that there are strongly $\aleph_1$-free groups of cardinality $\aleph_1$ which are not $\aleph_1$-separable (see [12]).

However, the existence of such groups is not settled by the hypothesis $2^{\aleph_0} = 2^{\aleph_1}$; specifically, in a model of MA + $\neg$CH every strongly $\aleph_1$-free group of cardinality $\aleph_1$ is $\aleph_1$-separable; but the methods of [3] show that it is consistent with $2^{\aleph_0} = 2^{\aleph_1}$ that there are strongly $\aleph_1$-free groups of cardinality $\aleph_1$ which are not $\aleph_1$-separable.

Now suppose $A$ is strongly $\aleph_1$-free and is a $W_\omega$-group. Consider a countable subgroup $B$ of $A$ such that $A/B$ is $\aleph_1$-free. We have a short exact sequence
\[ 0 \to B \to A \to A/B \to 0 \]
where the map of $B$ into $A$ is inclusion. Since $B$ is a free group of countable rank, if we knew that $A/B$ were a $W_\omega$-group, then we would have $\text{Ext}(A/B, \mathbb{Z}^{(\omega)}) = \text{Ext}(A/B, B) = 0$ and we could conclude that this sequence splits and hence $B$ is a direct summand of $A$. In every previously known model where there are non-free $W_\omega$-groups, the construction of a $W_\omega$-group $A$ is such that $A/B$ shares the properties of $A$ closely enough that $A/B$ is also a $W_\omega$-group — when $B$ is a countable subgroup such that $A/B$ is $\aleph_1$-free. (For example, if $A$ is constructed as in [1, Prop. XII.3.6(iii), p. 371], using a ladder system with a uniformization property, then $A/B$ shares the same properties, because it is constructed using essentially the same ladder system.)

Thus in these models the answer to (0.1) is affirmative. This motivates question (0.1) as well as the related question

(0.2) If a group $A$ of cardinality $\aleph_1$ is strongly $\aleph_1$-free and a $W_\omega$-group, and $B$ is a countable subgroup of $A$ such that $A/B$ is $\aleph_1$-free, is $A/B$ a $W_\omega$-group?

By what we have just remarked, a positive answer to (0.2) implies a positive answer to (0.1). The converse holds as well: if $A$ and $B$ are as in the hypotheses of (0.2) and $A$ is $\aleph_1$-separable, $A = F \oplus A'$ where $F$ is countable and contains $B$; then $A/B$ is a $W_\omega$-group because $A/B = F/B \oplus A'$ and $F/B$ is free by hypothesis on $B$.

We shall give a model of ZFC $+$ $\neg$CH where the answer to (0.1) and (0.2) is negative.

1 THE PROOF

Our main theorem is:

**Theorem 1** There is a strongly $\aleph_1$-free $W_\omega$-group $A$ of cardinality $\aleph_1$ with a countable subgroup $B$ of $A$ such that $A/B$ is $\aleph_1$-free but $B$ is not a direct summand of $A$.

Throughout, $E$ will be a stationary subset of $\omega_1$ consisting of limit ordinals, with (for technical reasons) $\omega \notin E$. We begin with a general construction of a group. Let $\pi_n$ be the $n$th prime.

---

1We do not know if Theorem 8 of the original paper is correct, or if the answer to question (0.3) is “no”.

2
Definition 2. For each $\delta \in E$ let $\eta_\delta$ be a ladder on $\delta$, that is, a strictly increasing function $\eta_\delta : \omega \to \delta$ whose range approaches $\delta$. Let $\varphi$ be a function from $E \times \omega$ to $\omega$. Let $F$ be the free abelian group with basis $\{x_\nu : \nu \in \omega_1\} \cup \{z_{\delta,n} : \delta \in E, n \in \omega\}$ and let $K$ be the subgroup of $F$ generated by $\{w_{\delta,n} : \delta \in E, n \in \omega\}$ where

$$w_{\delta,n} = \pi_n z_{\delta,n+1} - z_{\delta,0} - x_{\eta_\delta(n)} - x_{\varphi(\delta,n)}. \tag{1}$$

Let $A = F/K$.

Clearly $A$ is an abelian group of cardinality $\aleph_1$. Notice that because the right-hand side of (1) is 0 in $A$, we have for each $\delta \in E$ and $n \in \omega$ the following relation in $A$:

$$\pi_n z_{\delta,n+1} - z_{\delta,0} = x_{\eta_\delta(n)} + x_{\varphi(\delta,n)} \tag{2}$$

where, in an abuse of notation, we write, for example, $z_{\delta,n+1}$ instead of $z_{\delta,n} + K$. If we let

$$A_\alpha = \langle \{x_\nu : \nu < \alpha\} \cup \{z_{\delta,n} : \delta \in E \cap \alpha, n \in \omega\} \rangle. \tag{3}$$

for each $\alpha < \omega_1$, then for each $\delta \in E$, $z_{\delta,0} + A_\delta$ is non-zero and divisible in $A_{\delta+1}/A_\delta$ by $\pi_n$ for all $n \in \omega$. Thus $A_{\delta+1}/A_\delta$ is not free and hence $A$ is not free. (In fact $\Gamma(A) \supseteq E$; see [1] pp. 83ff.) Moreover, $A$ is strongly $\aleph_1$-free; in fact, for every $\alpha < \omega_1$, using Pontryagin’s Criterion we can show that $A/A_\alpha$ is $\aleph_1$-free whenever $\alpha \notin E$.

We now define the model of ZFC where $A$ is defined and has the desired properties. We begin with a model $V$ of ZFC where GCH holds, choose $E \in V$, and define the group $A$ in a generic extension $V^Q_0$ using generic ladders $\eta_\delta$, and generic $\varphi$. Specifically:

Definition 3. Let $Q_0$ be the set of all finite functions $q$ such that $\text{dom}(q)$ is a finite subset of $E$ and for all $\gamma \in \text{dom}(q)$, $q(\gamma)$ is a pair $(\eta_\delta^q, \varphi_\delta^q)$ where for some $r_\delta^q \in \omega$:

- $\eta_\delta^q$ is a strictly increasing function: $r_\gamma^q \to \gamma$;
- $\varphi_\delta^q : \{\gamma\} \times r_\gamma^q \to \omega$.

Clearly $Q_0$ is c.c.c. We now do an iterated forcing to make $A$ a $W_\omega$-group. We begin by defining the basic forcing that we will iterate.

Definition 4. Given a homomorphism $\psi : K \to \mathbb{Z}^{(\omega)}$, let $Q_\psi$ be the poset of all finite functions $q$ into $\mathbb{Z}^{(\omega)}$ satisfying:

There are $\delta_0 < \delta_1 < \ldots < \delta_m$ in $E$ and $\{r_\ell : \ell \leq m\} \subseteq \omega$ such that $\text{dom}(q) = \{z_{\delta,\ell,n} : \ell \leq m, n \leq r_\ell\} \cup \{x_\nu : \nu \in I_q\}$

where $I_q \subseteq \omega_1$ is finite and is such that for all $\ell \leq m$

$$\eta_{q_\delta}(n) \in I_q \iff n < r_\ell \tag{4}$$

and for all $\ell \leq m$ and $n < r_\ell$,

$$\psi(w_{\delta,\ell,n}) = \pi_n q(z_{\delta,\ell,n+1}) - q(z_{\delta,0}) - q(x_{\eta_\delta(\ell,n)}) - q(x_{\varphi(\delta,n)}). \tag{5}$$

Moreover, we require of $q$ that for all $\ell \neq j$ in $\{0, \ldots, m\}$,

$$\eta_{q_\delta}(k) \neq \eta_{q_\delta}(i) \text{ for all } k \geq r_j \text{ and } i \in \omega. \tag{6}$$
We will denote \{\delta_0, \ldots, \delta_m\} by \text{cont}(q) and \text{num}(q, \delta_i)$. The partial ordering on $Q_\psi$ is inclusion. Standard methods prove that $Q_\psi$ is c.c.c.

Let $P = \left\langle P_i, \hat{Q}_i : 0 \leq i < \omega_2 \right\rangle$ be a finite support iteration of length $\omega_2$ so that for every \(i \geq 1 \models_{P_i} \hat{Q}_i = Q_\psi\), where $\models_{P_i}$ is a homomorphism: $K \to \mathbb{Z}^{(\omega)}$, where the enumeration of names \{\hat{\psi}_i : 1 \leq i < \omega_2\} is chosen so that if $G$ is $P$-generic and $\hat{\psi} \in P[G]$ is a homomorphism: $K \to \mathbb{Z}^{(\omega)}$, then for some $i \geq 1$, $\hat{\psi}_i$ is a name for $\psi$ in $V^{P_i}$. Then $P$ is c.c.c. and in $V[G]$ every homomorphism from $K$ to $\mathbb{Z}^{(\omega)}$ extends to one from $F$ to $\mathbb{Z}^{(\omega)}$. This means that Ext($A, \mathbb{Z}^{(\omega)}$) = 0, that is, $A$ is a $W_\omega$-group (see, for example, [I] p.8).

Let $B = A_\omega$, i.e., the subgroup of $A$ generated by $\{x_\ell : \ell \in \omega\}$. It is easy to check that $A/B$ is $\aleph_1$-free. Now, aiming for a contradiction, suppose that in $V[G]$ there is a projection $h : A \to B$ (i.e., $h \upharpoonright B$ is the identity). Then there is a condition $p_o \in G$ such that

$$p_o \models \text{“} h : A \to B \text{ is a projection”}$$

where $h$ is a name for $h$.

For each ordinal $\xi \in \omega_1 - E$, choose a condition $p_\xi \geq p_o$ such that there is a $y_\xi \in V$ such that

$$p_\xi \models h(x_{\xi+1}) = y_\xi.$$

(That is, $y_\xi$ is an element of $B \cap V$, and not just a name.)

We can assume that

\[ (\dagger) \quad 0 \in \text{dom}(p_\xi); \text{ for each } j \in \text{dom}(p_\xi), p_\xi(j) \text{ is a function in } V \text{ and not just a name; } r_{\xi,0}^\xi(= r_\xi) \text{ is independent of } \gamma \in \text{dom}(p_\xi(0)); \text{ if } j \in \text{dom}(p_\xi) \setminus \{0\}, \text{ } \gamma \in \text{cont}(p_\xi(j)) \implies \gamma \in \text{dom}(p_\xi(0)) \text{ and } \text{num}(p_\xi(j), \gamma) (= r_{\xi,j}^\gamma) \leq r_\xi \text{ and independent of } \gamma. \]

When we say that “$\nu$ occurs in $p$” we mean that $\nu \in \text{dom}(p) \cup \text{dom}(p(0)) \cup \bigcup \{ \eta_\nu(n), \varphi(\delta, n) \} : \gamma \in \text{dom}(p(0)), n < r_{\nu,0}^\nu \}$ or $x_\nu$ belongs to the domain of some $p(j)$.

Without loss of generality we can assume (passing to a subset $S \subseteq \omega_1 - E$) by Fodor’s Lemma and the $\Delta$-system lemma that

\[ (\dagger \dagger) \quad \{ \text{dom}(p_\xi) : \xi \in S \} \text{ forms a } \Delta\text{-system, whose root we denote } C \text{ (i.e., } \text{dom}(p_{\xi_1}) \cap \text{dom}(p_{\xi_2}) = C = \{0, \mu_1, \ldots, \mu_d\} \text{ for all } \xi_1 \neq \xi_2 \in S); \text{ } r_\xi (= r) \text{ and } r_{\xi,j}^\gamma (= r_{\xi,j}^\gamma) \text{ are independent of } \xi; \text{ } \text{dom}(p_\xi(0)) \cap \xi \text{ is independent of } \xi; \text{ there is } m \text{ such that for all } \xi \in S, \text{dom}(p_\xi(0)) \setminus \xi = \{ \gamma_\xi,0 < \ldots < \gamma_\xi,m \} \text{ and for each } \ell \leq m \text{ there is } t_\ell \leq r - 1 \text{ such that } \eta_{\xi,\ell}(t_\ell - 1) < \xi \leq \eta_{\xi,\ell}(t_\ell) \text{ and for } i \leq t_\ell - 1, \eta_{\xi,\ell}(i) \text{ is independent of } \xi. \]

Moreover, for every $j \in C$, \{dom($p_\xi(j)$) : $\xi \in S\} \text{ forms a } \Delta\text{-system and for all } \xi_1 \neq \xi_2 \in S, p_{\xi_1}(j) \text{ and } p_{\xi_2}(j) \text{ agree on } \text{dom}(p_{\xi_1}(j)) \cap \text{dom}(p_{\xi_2}(j)).$

Let $p^*$ denote the “heart” of the $\Delta$-system; that is, dom($p^*$) = $C$ and for all $\mu \in C$, \text{dom}(p^*$($\mu$)) = dom($p_{\xi_1}(\mu)$) $\cap$ dom($p_{\xi_2}(\mu)$) = $C_\mu$, say) for $\xi_1 \neq \xi_2 \in S$; and $p^*$($\mu$) $\upharpoonright$ $C_\mu$ = $p_{\xi_1}(\mu)$ $\upharpoonright$ $C_\mu$.

We can assume that every ordinal which occurs in $p^*$ is $< \xi$ for every $\xi \in S$, and that for every $\xi_1 < \xi_2 \in S$, every $\nu$ which occurs in $\xi_1$ is $< \xi_2$. We can find $\delta \in E$ which is the limit of a strictly increasing sequence \{\$\xi_\ell : \ell \in \omega\\} $\subseteq S$. Notice that no ordinal $\geq \delta$ occurs in any
There is a condition $\tilde{p} \geq p^*$ which forces a value to $\hat{h}(z_{\delta,0})$, i.e., there is $y \in V$ such that $\tilde{p} \vDash \hat{h}(z_{\delta,0}) = y$. We can assume that $\tilde{p}$ is as in (†); let $r^* = \tilde{p}(0)$. Fix $n \in \omega$ sufficiently large so that every ordinal which occurs in $\tilde{p}$ but not in $p^*$ does not occur in $p_{\xi_n}$. Fix $k \in \omega$ such that $k > \sup\{j \in \omega : j \text{ occurs in } \tilde{p} \text{ or } p_{\xi_n}\}$ and such that $y, y_{\xi_n} \in \{x_j : j < k\}$. There is a condition $q_0$ extending $\tilde{p}(0)$ and $p_{\xi_n}(0)$ such that $q_0$ forces
\[
\eta_\delta(r^*) = \xi_n + 1; \quad \eta_\delta(r^* + 1) = \xi_{n+1}; \quad \text{and } \varphi(\delta, r^*) = k.
\]
Then there is a condition $q \in P$ extending $\tilde{p}$ and $p_{\xi_n}$ such that $q(0) \geq q_0$. (The only possible difficulty in defining $q(j)$ for $j > 0$ is in defining $q(j)(z_{\delta,r^*+1})$, $q(j)(\eta_\delta(r^*))$ and $q(j)(x_{\varphi(\delta,r^*)})$ to satisfy (5), but this can be done even though $q(j)(\eta_\delta(r^*)) = q(j)(x_{\xi_n+1})$ may be determined by $p_{\xi_n}(j)$, because $x_k$ is new.)

Now consider a generic extension $V[G']$ such that $q \in G'$. In this model, by (5), we have that in $A$, $\pi_n$ divides $z_{\delta,0} - x_{\eta_\delta(r^*)} - x_{\varphi(\delta,r^*)} = z_{\delta,0} - x_{\xi_n+1} - x_k$. Hence in $B$, $\pi_n$ divides $h(z_{\delta,0} - x_{\xi_n+1} - x_k) = y - y_{\xi_n} - x_k$. But this is impossible by choice of $k$.
