\textbf{Keywords:} Chiral Symmetry, Chiral Perturbation Theory, Pion–Pion Scattering

\textbf{Abstract}

We present technical details of the evaluation of the elastic $\pi\pi$ scattering amplitude to two loops in chiral perturbation theory. In particular, we elaborate on the renormalization procedure at the two–loop order and on the evaluation of the relevant Feynman diagrams that can all be expressed in terms of elementary functions. For the sake of clarity, we discuss these matters both in the $N$–component $\phi^4$ theory (in its symmetric phase) and in chiral perturbation theory. Estimates for the relevant low–energy constants of $O(p^6)$ are presented. Threshold parameters and phase shifts are then calculated for two sets of $O(p^4)$ coupling constants and compared with experiment. We comment on the extraction of threshold parameters from phase shift data.

1 Introduction

Elastic $\pi\pi$ scattering is a fundamental process for QCD at low energies. It provides an ideal testing ground for the mechanism of spontaneous chiral symmetry breaking. Since only the (pseudo-)Goldstone bosons of chiral $SU(2)$ are involved, one expects the low-energy expansion of the scattering amplitude to converge rather rapidly. The systematic procedure for this low-energy expansion is called chiral perturbation theory (CHPT) [1, 2, 3, 4].

In the framework of CHPT, the $\pi\pi$ scattering amplitude was evaluated at lowest order in the chiral expansion in [5] and to next-to-leading order in [2, 6]. The theoretical developments up to 1994 are summarized in [7, 8]. The forthcoming experimental improvements concerning $\pi\pi$ scattering are also discussed there. The amplitude to next-to-next-to-leading order was recently calculated in a dispersive approach in [9] and in the standard CHPT framework in [10]. Other developments since 1994 can be found in Refs. [11]-[20].

Both the explicit calculation of the Feynman diagrams and the renormalization procedure needed to evaluate the scattering amplitude at the two-loop order are quite involved. The main aim of the present article is to detail the methods used in [10] for that purpose.

The amplitude contains a nontrivial analytical part that can be expressed in terms of logarithms that generate the cuts required by unitarity. In addition, there is a contribution which consists of a polynomial in the external momenta. Our calculation reveals the dependence of the six coefficients in this polynomial on the pion mass and on the low-energy constants of both $O(p^4)$ and $O(p^6)$. We find that the complete two-loop amplitude can be expressed in terms of elementary functions.

We found it useful to first illustrate in Sect. 2 the corresponding calculation in the $N$-component $\phi^4$ theory (in its symmetric phase), where the algebraic manipulations needed are simple. The loop expansion is presented together with the renormalization at both the one- and two-loop levels. A technical issue that also comes up in the CHPT calculation is the use of the equations of motion (EOM) for the counterterms. We show how different forms of the counterterms at the one-
loop level lead to the same generating functional after a proper redefinition of the counterterms at the two–loop order.

In Sect. 3, the analogous calculation is performed in CHPT. The renormalization procedure is again discussed in detail, both for minimal subtraction and for the modified minimal subtraction that we actually use. For the effective chiral lagrangian, the role of EOM is similar as in \( \phi^4 \), albeit algebraically more involved. In Sect. 4, the results for the pion mass, the pion decay constant and the \( \pi\pi \) scattering amplitude are presented to \( O(p^6) \) in the modified minimal subtraction scheme. Here, we also compare our results with the calculation of Ref. [4].

In Sect. 5, we perform a numerical analysis to compare with experimental information. For this purpose, we first derive estimates for the low–energy constants of \( O(p^4) \). We include the effects of vector and scalar meson resonances and of \( K \) and \( \eta \) contributions. We then discuss numerically the sensitivity of the amplitude to those constants. We emphasize that the main uncertainties are due to the couplings of \( O(p^4) \). We use two sets of these couplings to illustrate the uncertainty: The first set used in [10] is essentially based on phenomenology to \( O(p^4) \) [2, 21]. For the second set, we use the present calculation to extract the couplings \( \hat{b}_1, \hat{b}_2 \) from the observed \( D \)-wave scattering lengths. For the two sets, we then analyse threshold parameters and phase shifts and compare them with available experimental results.

Sect. 6 contains our conclusions. Some technical aspects on the calculation of two–loop diagrams, the off–shell scattering amplitude of \( O(p^4) \) and analytic expressions for the scattering lengths as well as for the coefficients \( \hat{b}_i \) in the \( O(p^6) \) amplitude are relegated to four appendices.

## 2 \( N \)-component \( \phi^4 \) to two loops

As we have mentioned in the introduction, we illustrate the loop expansion in CHPT first with the \( N \)-component \( \phi^4 \) theory in the unbroken phase. For this purpose, we proceed in a manner as analogous as possible to the chiral expansion. In particular, we rely on the external field technique and use a procedure that is scale independent at each step, as is done in CHPT. We also comment on the role of counterterms that vanish upon use of the EOM and give the relation to the MS scheme.

### 2.1 The loop expansion

The loop expansion is equivalent to an expansion of the generating functional in powers of \( h \) – we therefore explicitly display \( h \) in this section. The lagrangian is

\[
\mathcal{L} = \frac{1}{2} (\partial_\mu \phi^T \partial^\mu \phi - M^2 \phi^T \phi) - \frac{g}{4} (\phi^T \phi)^2 - \phi^T f - \sum_{\nu=1}^{\infty} h^\nu C_\nu ,
\]

where the symbol \( \phi \) collects the \( N \) fields \( \phi_1, \ldots, \phi_N \),

\[
\phi^T = (\phi_1, \ldots, \phi_N)
\]

Below, we will use an analogous notation for any multicomponent vector, e.g., \( a^T = (a_1, a_2, a_3) \), etc. The quantities \( C_\nu \) denote the counterterms that remove the
ultraviolet singularities at order $h^\nu$. They are linear combinations of $O(N)$--invariant polynomials of dimension $\leq 4$. Considering the external field $f$ to be a spurion $O(N)$ vector and using partial integration to eliminate $\partial_\mu \phi^T \partial^\mu \phi$, one is left with

$$
P_1 = \frac{1}{2} \phi^T \Box \phi \ , \ P_2 = \frac{1}{2} M^2 \phi^T \phi \ , \ P_3 = \frac{g}{4} (\phi^T \phi)^2 \ , \ P_4 = \phi^T f \ .$$

As is shown below, one may eliminate one of these polynomials by use of the EOM. Here we discard $P_4$ and write

$$
P_T = (P_1, P_2, P_3) \ .$$

In the following we use dimensional regularization. As a result, the vectors $a$ and $b$ become $M$--independent functions of the space–time dimension $d$, divergent as $d \to 4$. The external field $f$ allows one to construct the generating functional by evaluating the vacuum–to–vacuum transition amplitude

$$
\exp\{iZ[f]/\hbar\} = N \int [d\phi] \exp\{iS/\hbar\} \ , \ S = \int dx \mathcal{L} \ .
$$

The normalization constant $N$ ensures that $Z[0] = 0$. Expanding the right–hand side in powers of $\hbar$ generates the series

$$
Z = Z_0 + \hbar Z_1 + \hbar^2 Z_2 + O(\hbar^3) \ .
$$

To arrive at the explicit expressions for the components $Z_i$, one considers fluctuations around the classical solution $\bar{\phi}$ that is determined by the external field through the EOM,

$$
(M^2 + \Box) \bar{\phi}^a + g \bar{\phi}^T \phi \bar{\phi}^a + f^a = 0 \ ; \ a = 1, \ldots, N \ .
$$

Below, barred quantities always denote quantities evaluated at (2.5), e.g.,

$$
\bar{S} = \int dx \mathcal{L}(\bar{\phi}[f], f) \ ,
$$

etc. We write the fluctuations in the form

$$
\phi = \bar{\phi} + \xi \ ,
$$

use translation invariance of the measure, $[d\phi] = [d\xi]$, and find

$$
\exp\{iZ/\hbar\} = N \exp\{i\bar{S}/\hbar\} \times \int [d\xi] \exp\{-i \hbar \int dx \left[ \frac{1}{2} \xi^T D \xi + F(\xi, \bar{\phi}) \right]\} \ .
$$

The differential operator $D$ acts in coordinate and flavour space,

$$
D^{ab} = D_0^{ab} + \sigma^{ab} \ ,
$$

$$
D_0^{ab} = (M^2 + \Box) \delta^{ab} \ , \ \sigma^{ab} = g \{ \bar{\phi}^T \delta^{ab} + 2 \bar{\phi}^a \bar{\phi}^b \} \ .
$$
Furthermore, considering the fluctuations to be of order $\hbar^{1/2}$, the quantity $F$ starts at order $\hbar^{3/2}$. For the evaluation of the generating functional at two-loop order, it is sufficient to keep terms of order $\hbar^2$ in $F$,

$$F = g_\xi T \xi^T \phi + \frac{g}{4} (\xi^T \xi)^2 + h g \{ \xi^T d_1 \phi + \xi^T d_2 \phi \} + O(\hbar^{5/2})$$

$$a_{1}^{ab} = (a_1 \Box + a_2 M^2 + a_3 g \phi^T \phi) \delta^{ab}$$

$$a_{2}^{ab} = \frac{1}{2} (a_1 \Box + a_2 M^2) \delta^{ab} + \frac{a_3}{2} \sigma^{ab}$$

(2.10)

We then arrive at the following expressions for the components $Z_i$,

$$Z_0 = -\frac{1}{2} \int dx \left\{ \mathcal{T}_1 - 2\mathcal{T}_3 \right\}$$

$$Z_1 = \frac{1}{2} \int dx \left\{ i \langle \ln(1 + D_0^{-1}) \rangle - 2\mathcal{C}_1 \right\}$$

$$Z_2 = -g^2 \int dxdy \bar{\phi}_x^T \left\{ 2G_{xy}^3 + G_{xy}\langle G_{xy}^2 \rangle \right\} \phi_y$$

$$+ \frac{g}{4} \int dx \left\{ \left[ \langle G_{xx}^2 \rangle + 2 \langle G_{xy}^2 \rangle \right] - \left[ \cdots \right]_{\phi=0} \right\}$$

$$- \frac{g^2}{2} \int dxdy \bar{\phi}_x^T \left\{ \langle G_{xx} \rangle + 2G_{xx} + id_{1x} \right\} G_{xy} \times$$

$$\langle G_{yy} \rangle + 2G_{yy} + id_{1y} \} \phi_y$$

$$+ ig \int dx \left\{ \langle d_{2y} G_{yx} \rangle_{y=x} - \langle \cdots \rangle_{y=x,\phi=0} \right\}$$

$$- \int dx \mathcal{C}_2$$

(2.13)

Here we have introduced the propagator in the presence of the external field $f$,

$$G_{xy} = \int_0^\infty d\lambda \langle x|e^{-\lambda D}|y \rangle$$

$$D_{x}^{ab} G_{xy}^{bc} = \delta^{ac} \delta^{(d)}(x-y)$$

(2.14)

The symbol $\langle A \rangle$ denotes the trace of the matrix $A$ in flavour space, and $\bar{\phi}_x = \bar{\phi}(x)$. The various contributions to $Z_2$ are illustrated in Fig. 1.

The numbering is such that the contribution (2.13 a) corresponds to Fig. 1a, etc. We refer in the following to Fig. 1b (b) as the sunset (butterfly) diagram, respectively. Below, we will also need the free propagator,

$$\Delta_{xy} = G_{xy}|_{f=0}$$

(2.15)

which is a diagonal $N \times N$ matrix in flavour space.

### 2.2 Renormalization

The above expressions have a well-defined limit as the space-time dimension $d$ reaches its physical value $d = 4$ only for an appropriately chosen singular behaviour of the vectors $a$ and $b$ as $d \to 4$. In this subsection, we display and comment these singularities and start the discussion with the one-loop graphs.
2.2.1 One–loop diagrams

The singularities at one–loop order may easily be identified by writing

\[ \langle \ln(1 + D_{0}^{-1}\sigma) \rangle = \langle D_{0}^{-1}\sigma \rangle - \frac{1}{2} \langle D_{0}^{-1}\sigma D_{0}^{-1}\sigma \rangle + \cdots, \]

where the terms omitted are finite at \( d = 4 \). Evaluating the trace and keeping only the singular terms at \( d = 4 \) gives

\[ i \int dx \langle \ln(1 + D_{0}^{-1}\sigma) \rangle = -g(N + 2)T_{M} \int dx \, \bar{\phi}^T \phi - \frac{g^2}{2}(N + 8)\dot{T}_{M} \int dx \, (\bar{\phi}^T \phi)^2 + \cdots, \]

where the tadpole integral \( iT_{M} \) is the free propagator at coinciding arguments in coordinate space,

\[ T_{M} = \frac{1}{i} \int_{0}^{\infty} d\lambda \langle x | e^{-\lambda D_{0}} | x \rangle = \frac{M^{d-2}}{(4\pi)^{d/2}} \Gamma(1 - d/2), \tag{2.16} \]

and

\[ \dot{T}_{M} \doteq \partial_{M^2}T_{M} = -\frac{M^{d-4}}{(4\pi)^{d/2}} \Gamma(2 - d/2). \tag{2.17} \]
To determine $C_1$, we work out the singular part in the integrals $T_M$ and $\dot{T}_M$. We introduce the scale $\mu$, 

$$M^{2w} = \mu^{2w}(M/\mu)^{2w}, \ w = d/2 - 2,$$

and obtain 

$$T_M = \frac{M^2}{16\pi^2}\mu^{2w}\left\{\frac{1}{w} + a(M/\mu) - 1 + b(M/\mu)w + O(w^2)\right\},$$  
$$\dot{T}_M = \frac{\mu^{2w}}{16\pi^2}\left\{\frac{1}{w} + a(M/\mu) + c(M/\mu)w + O(w^2)\right\},$$

(2.18)

with 

$$a(M/\mu) = \ln(M^2/\mu^2) - \Gamma'(1) - \ln(4\pi).$$

(2.19)

The functions $b(M/\mu)$ and $c(M/\mu)$ will not be needed in explicit form in the following. Since we have introduced the scale $\mu$ in such a manner that $T_M$ and $\dot{T}_M$ are scale–independent, we may use scale–independent counterterms as well, 

$$a_1 = 0,$$

$$a_2 = \frac{\mu^{2w}}{16\pi^2}\left\{-\frac{(N+2)}{w} + a_2^r(\mu, w)\right\},$$

$$a_3 = \frac{\mu^{2w}}{16\pi^2}\left\{-\frac{(N+8)}{w} + a_3^r(\mu, w)\right\},$$

(2.20)

where the renormalized couplings $a_i^r(\mu, w)$ are finite at $w = 0$, with 

$$\left(\mu\frac{\partial}{\partial \mu} + 2w\right)a_2^r(\mu, w) = 2(N+2),$$

(2.21)

and analogously for $a_3$. With the choice (2.20, 2.21), the one–loop functional $Z_1$ is scale independent and finite at $d = 4$.

### 2.2.2 Two–loop diagrams

In the next step, we determine the counterterms that render the two–loop contributions finite at $d = 4$. For this purpose, we identify the singular part of the full propagator [22], 

$$S_{xy} = \Delta_{xy} + \sigma_x\dot{\Delta}_{xy},$$

$$\dot{\Delta}_{xy} = \partial_{M^2}\Delta_{xy}.$$ 

The remainder $R$, 

$$G_{xy} = S_{xy} + R_{xy},$$

(2.22)
is finite at \( x = y \). The decomposition (2.22) generates in the two–loop functional \( Z_2 \) terms of the form \( R^3, R^2 S, RS^2 \) and \( S^3 \). A closer examination reveals that all nonlocal singularities proportional to \( R \) and to \( R^2 \) cancel out after putting in the values of the \( a_i \) from Eq. (2.20). The divergent contribution to \( Z_2 \) is therefore obtained by replacing everywhere in \( Z_2 \) the propagator \( G \) by its singular part, \( G \rightarrow S \). We now sketch how the singular pieces are evaluated, and consider for illustration the part proportional to \( G^3 \) in Eq. (2.13 a) that contributes to the sunset diagram \( \text{Fig. 1a} \). After \( G \rightarrow S \), we expand the field \( \bar{\phi}_y \) around \( y = x \) and are then left with divergent vacuum integrals of the form

\[
\int dx \left( \Delta^3_{xy}; \Delta^2_{xy} \phi_y \right) (1; (x - y)^\mu (x - y)^\nu) . \tag{2.23}
\]

The integrals proportional to \( \Delta^3_{xy} \) correspond to the sunset integrals \( H \) and \( H^\mu\nu \) discussed in appendix \[. \] The integrals that contain \( \Delta^2_{xy} \) can be evaluated in a similar manner. Proceeding in an analogous fashion for the remaining contributions to \( Z_2 \), we finally find that the following counterterms render the two–loop functional finite at \( d = 4 \):

\[
\begin{align*}
b_1 &= \left( \frac{\mu^2 w}{16\pi^2} \right)^2 \left\{ \frac{(2 + N)}{2w} + \beta_1'(\mu, w) \right\} , \\
b_2 &= \left( \frac{\mu^2 w}{16\pi^2} \right)^2 \left\{ \frac{(5 + N)(2 + N)}{w^2} + \frac{(2 + N)}{w} \left( 3 - a_2'(\mu, w) - a_3'(\mu, w) \right) + \beta_2'(\mu, w) \right\} , \\
b_3 &= \left( \frac{\mu^2 w}{16\pi^2} \right)^2 \left\{ \frac{(8 + N)^2}{w^2} + \frac{2}{w} (22 + 5N - (8 + N)a_3'(\mu, w)) + \beta_3'(\mu, w) \right\} .
\end{align*}
\tag{2.24}
\]

Remark: In Eq. (2.24), the full contribution \( a_{2,3}^*(\mu, w) \) to the singular part in \( b_{2,3} \) occurs. We could have expanded \( a_{2,3}^*(\mu, w) \) around \( w = 0 \) in (2.20) – then, only \( a_{2,3}^*(\mu, 0) \) would occur in (2.24). In order to keep \( a_{2,3} \) scale independent, additional terms of order \( O(w) \) must then be added in (2.20). From (2.24) it is clear that these would contribute a local part to \( Z_2 \) that could then be removed with a redefinition of the renormalized couplings \( \beta_i'(\mu, w) \). The definition (2.20) allows one to do all this in one go.

2.2.3 The role of the equations of motion

We come back to the choice of the counterterms \( C_i \). In the generating functional, they are evaluated at the solution to the EOM. This amounts to a linear relation among the \( P_i \),

\[
\begin{align*}
E &= 2P_1 + 2P_2 + 4P_3 + P_4 , \\
\frac{E}{d} &= 0 .
\end{align*}
\tag{2.25}
\]

The following discussion is adapted to CHPT, where the higher–order lagrangians \( \mathcal{L}_4, \mathcal{L}_6, \ldots \) take the role of the counterterms \( C_1, C_2, \ldots \).
As we already mentioned, one may therefore remove one of the $P_i$ from the list (2.2). We may e.g., eliminate $P_3$ instead of $P_4$ as above,

$$C_1 \rightarrow C'_1 = g a'^T P' , \quad P'^T = (P_1, P_2, P_4). \tag{2.26}$$

Using the identity

$$a'^T P' = c^T P + a'_3 E , \quad c^T = (a'_1 - 2a'_3, a'_2 - 2a'_3, -4a'_3) , \tag{2.27}$$

it is seen that a different choice of the counterterm at one–loop order amounts to adding to the lagrangian a term that vanishes at the solution to the EOM. As we now demonstrate, the use of $C'_1$ requires that the counterterm at two–loop order must be adapted accordingly,

$$C_2 \rightarrow C'_2 = g^2 b'^T P . \tag{2.28}$$

In $C'_2$, we use again $P$ – the freedom in the choice of polynomials occurs at each order in the perturbative expansion. We denote by $Z'_1, Z'_2$ the generating functional obtained with (2.26, 2.28). For the one–loop functional to be finite at $d = 4$, the integrals $\int dx C'_1$ and $\int dx C'_2$ must have the same singularities. According to the relation (2.27), this requirement is satisfied with

$$a'^T = (-\frac{a_3}{2}, a_2 - \frac{a_3}{2}, -\frac{a_3}{4}) . \tag{2.29}$$

The replacement $C_1 \rightarrow C'_1$ then amounts to

$$C_1 \rightarrow C_1 + \kappa g E , \tag{2.30}$$

with $\kappa = -a_3/4$. This transformation obviously leaves the one–loop functional unchanged. Repeating the calculation of $Z'_2$ with (2.30), one finds

$$Z'_2 = Z_2 + \int dx \left( B'_2 - B'_2 \right) + Q ,$$

where $Q$ is a local action,

$$Q = -g^2 \kappa \int dx e^T P , \quad e^T = (2a_1 + \kappa, 2a_2 + \kappa, 4a_3 + 6\kappa) . \tag{2.31}$$

In addition to the singularities in $Z_2$, the counterterm $C'_2$ has to cancel the ones in $Q$ as well. Because the latter is a local action, it can be removed from $Z'_2$ altogether with

$$b' = b + \kappa e .$$

In summary, a different choice of the counterterm at one–loop order amounts to adding a term to the lagrangian that vanishes at the solution to the EOM, see Eq. (2.30). That transformation leaves $Z_1$ untouched and changes $Z_2$ by a local action $Q$ which can be completely removed by an appropriate choice of the counterterm at two–loop order,

$$\left( \begin{array}{c} C_1 \rightarrow C_1 + \kappa g E \\ C_2 \rightarrow C_2 + g^2 e^T P \end{array} \right) \rightarrow Z'_1 = Z_1, Z'_2 = Z_2 . \tag{2.32}$$
2.2.4 Connection with the MS scheme

The above renormalization scheme generates scale–independent quantities at each step. In particular, individual Feynman diagrams are independent of \( \mu \). The Green functions so evaluated at one–loop accuracy contain the finite parameters \( M^2, g, a_i(\mu, 0), b_i(\mu, 0), \ldots \). An analogous procedure is used in chiral perturbation theory [4]. We find it useful to compare at this stage this scheme with the MS scheme in conventional perturbative calculations. There, one starts from the bare lagrangian

\[
\mathcal{L} = \frac{1}{2} (\partial_\mu \phi_B^T \partial^\mu \phi_B - M_B^2 \phi_B^T \phi_B) - \frac{g_B}{4} (\phi_B^T \phi_B)^2 \tag{2.33}
\]

and sets at one–loop order

\[
g_B = \mu^{-2w} g_r(\mu) \left\{ 1 - \frac{(N + 8)}{16\pi^2 w} g_r(\mu) + O(g_r^2) \right\} ,
\]

\[
M_B^2 = g_r(\mu) \left\{ 1 - \frac{(N + 2)}{16\pi^2 w} g_r(\mu) + O(g_r^2) \right\} . \tag{2.34}
\]

The two schemes can easily be related by evaluating, e.g., the physical mass \( M_P \) and the elastic scattering amplitude to one–loop accuracy. This is done in the following subsection in the present scheme. Repeating that calculation with (2.33, 2.34) and identifying the one–loop expressions gives

\[
g_r(\mu) = g(1 + \frac{g a_i^r}{16\pi^2} + O(g^2)) ,
\]

\[
M_r^2(\mu) = M^2(1 + \frac{g a_i^r}{16\pi^2} + O(g^2)) .
\]

Here and in the following we use the notation

\[
a_i^r \equiv a_i^r(\mu, 0) , \quad b_i^r \equiv b_i^r(\mu, 0) .
\]

From the scale dependence of the renormalized couplings \( a_2^r, a_3^r \) one reads off the scale dependence of \( M_r^2, g_r \) that guarantees scale independence of physical quantities. Analogous relations hold to all orders in the perturbative expansion.

2.3 Two– and four–point functions

For illustration, we evaluate the two– and four–point functions. It allows us to explain the methods used in Ref. [10] for the evaluation of the \( \pi \pi \) scattering amplitude in CHPT.

\[\text{2Of course, since the present theory is renormalizable, these parameters occur in such a combination that they can be lumped into, e.g., the physical mass } M_P \text{ and the physical coupling constant.}\]
Figure 2: Diagrams that contribute to the two–point function at two–loop order. A filled square (open square) stands for the contributions from the counterterm $C_1(C_2)$.

2.3.1 Two–point function

To evaluate the two–point function

$$i \langle 0 | T \phi^a(x) \phi^b(y) | 0 \rangle_{\text{conn}} = \delta^{ab} \Delta'_{xy} = \delta^{ab} \left( N^{-1} \langle \Delta_{xy} \rangle + O(g) \right) ,$$

we may either calculate the relevant Feynman diagrams displayed in Fig. 2 or determine the contribution of order $f^2$ to the generating functional, because

$$\delta^{ab} \Delta'_{xy} = \frac{\delta^2 Z}{\delta f^a_x \delta f^b_y} \bigg|_{f=0} .$$

We first proceed in this manner and find

$$Z = \frac{1}{2} \int dx \, \bar{\phi}^a_x K_{xy} \phi^b_y + O(h^3, \bar{\phi}^4) ,$$

$$K_{xy} = \delta^4(x - y)(A \Box_y + B) + C \Delta_{xy} + D \Delta^3_{xy}$$
with
\[ A = 1 - g^2 b_1 , \]
\[ B = M^2 - g m^2 - g^2 \left\{ b_2 M^2 + (N + 2)(a_3 T_M + m^2 T_M) \right\} , \]
\[ C = g^2 m^4 , \]
\[ D = -2 g^2 (N + 2) , \]
\[ m^2 = a_2 M^2 + (N + 2) T_M . \]  

(2.37)

Next we consider the Fourier transform
\[ \triangle' (p^2) = \int d^4 x e^{-i p \cdot (x-y)} \triangle'_{xy} \]
\[ = \frac{1 - g^2 b_1}{M^2 - p^2 - B + M^2 A - 2 g^2 (N + 2) H(p^2)} + O(g^3) , \]  

(2.38)

where \( H(p^2) \) denotes the sunset integral \((A.9)\). Expanding \( H(p^2) \) around \( p^2 = M^2 \) gives at \( d = 4 \)
\[ \triangle' (p^2) = \frac{Z \phi}{M_p^2 - p^2} + R \phi (p^2) + O(g^3) , \]  

(2.39)

with
\[ Z \phi = 1 + g^2 \frac{1}{(16 \pi^2)^2} \left( (N + 2) \left( \frac{3}{4} + a(M/\mu) \right) - b_1 \right) + O(g^3) , \]  

(2.40)

and
\[ R \phi (p^2) = 2 g^2 (N + 2) H(p^2) . \]  

(2.41)

An integral representation for the twice subtracted sunset integral \( \overrightarrow{H}(p^2) \) – which is regular at \( p^2 = M_p^2 \) – is given in \((A.12)\). Finally, the physical mass \( M_p \) can be easily evaluated from Eqs. \((2.38, A.13)\) to two loops. The expansion starts with
\[ M_p^2 = M^2 + g m^2 + O(g^2) \]
\[ = M^2 \left\{ 1 + \frac{g}{16 \pi^2} [(N + 2)(a(M/\mu) - 1) + a_2^2] + O(g^2) \right\} . \]  

(2.42)

We add a remark concerning the calculation of the two–point function from the Feynman diagrams displayed in Fig. 4. Instead of evaluating the diagrams \( d_1, \ldots, d_9 \) individually, one may calculate the tree and tadpole graphs shown in Fig. 8, where the dashed and double lines stand for the propagators
\[ \frac{1}{M_1^2 - p^2} , \quad M_1^2 = M^2[1 + g a_2 + g^2 (b_2 - b_1)] \quad \text{ (dashed line)} \]
\[ \frac{1}{M_2^2 - p^2} , \quad M_2^2 = M^2 + g m^2 \quad \text{ (double–line)} \]

and where the vertex denotes the coupling \( g(1+a_3 g) \). The sum of these two diagrams is
\[ \frac{1}{M_3^2 - p^2} , \quad M_3^2 = M_1^2 + g(1+a_3 g)(N+2)T_{M_2} , \]  

(2.43)

where the argument in the tadpole integral is \( M_2 \). The expression \((2.43)\) is equal to the sum of the graphs \( d_1, \ldots, d_9 \) up to terms beyond two loops.
2.3.2 Four–point function

The number of diagrams at two–loop order becomes quite large – of course even more so in the case of CHPT. In the case of the two–point function, we have just seen that almost all graphs in Fig. 2 can be summed up by evaluating the tadpole diagram shown in Fig. 3. Here we wish to illustrate an analogous method to evaluate the elastic scattering amplitude (four–point function) to two loops. Whereas the method does not really pay off in the case of the \(N\)-component \(\phi^4\) theory considered here, it turns out to be very useful in CHPT. Furthermore, a similar procedure works in the evaluation of form factors\(^3\). The four–point function is of the form

\[
i^3 \int dx_1 \, dx_2 \, dx_3 \, e^{-i(p_1 x_1 + p_2 x_2 - p_3 x_3 - p_4 x_4)} \langle 0 | T \phi_i(x_1) \phi_k(x_2) \phi_l(x_3) \phi_m(x_4) | 0 \rangle = Z_\phi^2 \prod_i (M^2 - p_i^2) T_{im;ik}(s, t, u; p_1^2, p_2^2, p_3^2, p_4^2) ,
\]

with

\[
p_1 + p_2 = p_3 + p_4 , \\
s = (p_1 + p_2)^2 , \quad t = (p_1 - p_3)^2 , \quad u = (p_1 - p_4)^2 .
\]

The scattering amplitude is obtained by putting all momenta on the mass shell,

\[
T_{im;ik}(s, t, u; p_1^2, p_2^2, p_3^2, p_4^2)|_{p_i^2=M^2} = \delta_{ik} \delta_{lm} A(s, t, u) + \text{cycl.} .
\]

To determine the amplitude \(A(s, t, u)\), it suffices to calculate the matrix element for the indices

\[
i = k = 1 , \quad m = l = N .
\]

The relevant graphs up to \(O(g^3)\) are displayed in Fig. 4. The numbers attached on the external lines denote the relevant momenta, \(i \leftrightarrow p_i\). The group indices and crossed diagrams are not shown, and mass and counterterm insertions on the external lines are not displayed.

We use the obvious notation

\[
A(s, t, u) = gA^{(1)} + g^2 A^{(2)} + g^3 A^{(3)} + O(g^4) .
\]

\(^3\)This method has already been used in [23, 24] in connection with the evaluation of the process \(\gamma\gamma \rightarrow \pi\pi\) to two loops.
The elastic $\phi \phi \rightarrow \phi \phi$ scattering amplitude to two loops. The numbers on the external lines denote the momenta. Crossed diagrams and insertions on external lines are not displayed. A filled box (open box) denotes contributions from the counterterm $C_1(C_2)$.

The tree-level and one-loop results are

\[
A^{(1)}(s, t, u) = -2, \\
A^{(2)}(s, t, u) = -\frac{2}{16\pi^2} \left[ a_5^2 + (N + 8)a(M/\mu) \right] \\
+ 2(N + 4)\bar{J}(s) + 4 \left[ \bar{J}(t) + \bar{J}(u) \right],
\]

with

\[
\bar{J}(z) = \frac{1}{16\pi^2} \left[ \sigma \ln \frac{\sigma - 1}{\sigma + 1} + 2 \right]; \quad \sigma = \left( 1 - 4M^2/z \right)^{\frac{1}{2}}.
\]

The calculation at two-loop order may be made more economical by using the renormalized one-loop off-shell amplitude as a single (nonlocal) vertex. Then, a
large part of the two-loop diagrams can be obtained automatically by making a
one-loop calculation where one of the vertices is the one-loop amplitude, and the
other is the standard tree-level vertex. To be more specific, consider the diagrams
Fig. 4c 1,...,c 5 . They can be calculated by evaluating the integrals indicated in
Fig. 5. The notation is as follows: The double lines denote off-shell legs (the
corresponding off-shell amplitude is defined in (2.44)). These legs carry momenta
\( l \) and \( (p_1 + p_2 - l) \), and group index \( n \). The integration has to be done with weight
\[
\frac{1}{(M^2 - l^2)(M^2 - (p_1 + p_2 - l)^2)}.
\]
From this sum, one has to subtract the diagram Fig. 4c 3 . The result equals the
diagrams Fig. 4c 1,...,c 5 .

One may easily check the correctness of this statement, if one singles out of
the full one-loop amplitude one particular diagram. In this manner one generates
a single two-loop diagram with a symmetry factor in front of it: One can then
compare this to what one would get from a standard Feynman diagram calculation.
Similar formulae hold, of course, for the crossed versions of these diagrams.

After checking that the method is correct, the second question to be answered is
how one can do Feynman loop integrals with a nonlocal vertex in it. In particular,
how does one perform the following integral:
\[
\int \frac{d^dl}{(2\pi)^d} \frac{J((l - p_3)^2)}{(M^2 - l^2)(M^2 - (p_1 + p_2 - l)^2)}.
\]  
(2.49)

First we remark that this integral has to be calculated anyway, even if one would
try to calculate directly the two-loop diagrams. It corresponds to the fish diagram
in Fig. 4c 1 , where the divergence of the one-loop subdiagram has already been
cancelled by the insertion of the counterterm Fig. 4c 5 . As can be seen here, one
of the advantages of the method is that one starts the calculation at a stage where
the one-loop subdivergence has already been subtracted. This fact is of relevance
in particular in CHPT, where one may thus first do the renormalization of the off-
shell one-loop amplitude before diving into the forest of two-loop integrals. Next we

\footnote{The subtraction of the subdivergence in the diagram Fig. 4c 3 is much easier to accomplish, because the corresponding integral is a product of two one-loop integrals.}
note that the loop function $\bar{J}(s)$ admits a dispersive representation in $d$ dimensions $^{23, 24}$:

\[
\bar{J}(t) = t \int_{4M^2}^{\infty} \frac{[dx]}{x(x-t)}, \tag{2.50}
\]

where the measure $[dx]$ is given in appendix A (for $M^2 = 1$). By inserting this expression into Eq. (2.49) we see that the problem is transformed into the calculation of a one–loop integral with three propagators, where one of the propagators has a variable mass over which we finally have to integrate:

\[
\int_{4M^2}^{\infty} \frac{[dx]}{x} \int \frac{d^d l}{(2\pi)^d} \frac{(l-p_3)^2}{(M^2 - l^2)(M^2 - (l-p_3-p_4)^2)(x-(l-p_3)^2)} \tag{2.51}
\]

We discuss in appendix A how this integral can be done explicitly $^{30}$.

Finally, we are left with the graphs that we have not yet taken into account: The tadpole and counterterm insertions displayed in Fig. $^4$, can easily be taken care of by simply replacing in the one–loop integrals the parameter $M$ with the physical mass $M_P$. The contributions from wave function renormalization is taken care of by multiplying the tree graph with $Z^2_\phi$.

In summary, the advantages of the approach just described are that i) by using the renormalized one–loop amplitude as a single nonlocal vertex, the divergences due to one–loop subgraphs in nonfactorizable integrals never appear; ii) the diagrams that produce the mass renormalization inside the one–loop amplitude are taken into account trivially and do not have to be calculated explicitly; iii) the method also applies to the calculation of form factors, or any process where one part is given by an elastic two–body process like $\gamma \gamma \rightarrow \pi\pi$ $^{23}$; iv) the method can easily be implemented into a computer algebra program like FORM $^{25}$.

3 CHPT to two loops

In the following we discuss the methods used in Ref. $^{10}$ to evaluate the elastic $\pi\pi$ scattering amplitude to two loops in the framework of CHPT. This section contains details concerning renormalization, whereas the two–loop expressions for the pion mass, the pion decay constant and the scattering amplitude are given in the following section.

3.1 The lagrangian

The effective lagrangian consists of a string of terms,

\[
\mathcal{L}_{\text{eff}} = \mathcal{L}_2 + \hbar \mathcal{L}_4 + \hbar^2 \mathcal{L}_6 + \ldots \tag{3.1}
\]

Depending on the application one has in mind, one has to keep external fields in $\mathcal{L}_{\text{eff}}$. In the present case, we wish to calculate $M_\pi$, $F_\pi$ and the $\pi\pi$ scattering amplitude. The pion mass and the scattering amplitude may both be calculated from on–shell
quantities, and external fields are thus not necessary. On the other hand, the pion
decay constant needs a weak current as an external probe – it is an off–shell quantity,
not accessible through on–shell matrix elements. The use of the axial current to
evaluate $F_\pi$ to two loops is cumbersome because of the presence of Lorentz indices.
In the following, we use instead the two–point function of pseudoscalar densities. A
Ward identity relates the residue of this quantity to the pion decay constant.

There are many choices for the pion fields to be used in the effective lagrangians.
Of course, the result for physical quantities is always the same. A convenient choice
to minimize the number of diagrams is the sigma model parametrization. In the
following we work in the isospin symmetry limit $m_u = m_d$. We have

$$L_2 = \frac{F^2}{4} \langle u_\mu u^\mu + \chi_+ \rangle,$$  \hspace{1cm} (3.2)

with

$$U = \sigma + i \frac{\phi}{F}, \quad \sigma^2 + \frac{\phi^2}{F^2} = 1,$$

$$\phi = \begin{pmatrix} \pi^0 & \sqrt{2}\pi^+ \\ \sqrt{2}\pi^- & -\pi^0 \end{pmatrix} = \phi^i \tau^i,$$

$$u_\mu = i u^\dagger \partial_\mu u^\dagger = -i u \partial_\mu U^\dagger u = u_\mu^\dagger,$$

$$\chi_+ = u^\dagger \chi u^\dagger + u \chi^\dagger u,$$

$$\chi = 2B(\hat{m} 1 + ip), \quad \hat{m} = \frac{1}{2}(m_u + m_d),$$  \hspace{1cm} (3.3)

with $u^2 = U$. Furthermore, $p = p^i \tau^i$ is the external pseudoscalar field referred
to above. The symbol $\langle A \rangle$ denotes the trace of the two–by–two matrix $A$. The
lagrangian $L_4$ is [2]

$$L_4 = \sum_{i=1}^4 l_i P_i + \ldots,$$  \hspace{1cm} (3.4)

where

$$P_1 = \frac{1}{4} \langle u^\mu u_\mu \rangle^2, \quad P_2 = \frac{1}{4} \langle u_\mu u_\nu \rangle \langle u^\mu u^\nu \rangle, \quad P_3 = \frac{1}{16} \langle \chi_+ \rangle^2, \quad P_4 = \frac{i}{4} \langle u_\mu \chi^\mu \rangle,$$  \hspace{1cm} (3.5)

with

$$\chi^\mu = u^\dagger \partial^\mu \chi u^\dagger - u \partial^\mu \chi^\dagger u.$$  \hspace{1cm} (3.6)

The ellipsis in Eq. (3.4) denotes terms that do not contribute to the quantities con-
sidered here. The low–energy constants $l_i$ are divergent and remove the ultraviolet
divergences generated by one–loop graphs from $L_2$. We discuss them in more detail
below.

The complete effective lagrangian $L_6$ is not yet available: Whereas the list of the
necessary counterterms has been published [26], their divergence structure at $d = 4$ is
The knowledge of these would provide us with a check on the calculation, because these divergences must cancel the ones that we find in the two–loop calculation. Apart from this check, however, that analysis would not be of further use in the present context, because the scale–dependent finite pieces of those couplings are still largely unknown. Nevertheless, the structure displayed in [26] shows that there are no algebraic constraints between the counterterms at $O(p^6)$ needed in the expressions for the pion mass, pion decay constant or $\pi\pi$ scattering amplitude.

For the following considerations, it is useful to recall that the expansion in powers of the momenta is equivalent to an expansion in inverse powers of $F^2$. In an obvious notation, the chiral expansion for the pion mass, the pion decay constant and the elastic $\pi\pi$ scattering amplitude is

$$M^2_\pi = M^2 \left\{ 1 + m_4 \frac{M^2}{F^2} + m_6 \frac{M^4}{F^4} + O(F^{-6}) \right\},$$

$$F_\pi = F \left\{ 1 + f_4 \frac{M^2}{F^2} + f_6 \frac{M^4}{F^4} + O(F^{-6}) \right\},$$

$$A(s, t, u) = A_2 \frac{F^2}{F^2} + A_4 \frac{F^4}{F^4} + A_6 \frac{F^6}{F^6} + O(F^{-8}).$$

(3.7)

The one–loop contributions $m_4, f_4$ and $A_4$ have been determined in [4] – here, we calculate $m_6, f_6$ and $A_6$. Therefore, we need to keep in the effective lagrangian only contributions up to $O(F^{-6})$. We write symbolically

$$\mathcal{L}_2 = \mathcal{L}_{kin} + a_1 \frac{\phi^4}{F^2} + a_2 \frac{\phi^6}{F^4} + a_3 \frac{\phi^8}{F^6} + O(F^{-8}),$$

$$\mathcal{L}_4 = b_1 \frac{\phi^2}{F^2} + b_2 \frac{\phi^4}{F^4} + b_3 \frac{\phi^6}{F^6} + O(F^{-8}),$$

$$\mathcal{L}_6 = c_2 \frac{\phi^2}{F^4} + c_3 \frac{\phi^4}{F^6} + O(F^{-8}),$$

(3.8)

where the dimension of the couplings is

$$[a_i] = \text{mass}^2, \quad [b_i] = \text{mass}^4, \quad [c_i] = \text{mass}^6.$$ 

(3.9)

In order to generate a term of order $F^{-2m}$, one has to consider all products

$$a_{m_1}^{m_1} b_{m_2}^{m_2} c_{m_3}^{m_3}; \quad m_1 n_1 + m_2 n_2 + m_3 n_3 = m.$$

(3.10)

Furthermore, it is very convenient to collect the terms quadratic in the pion fields in the kinetic part and to expand in powers of $b_1$ and $c_2$ only afterwards. As a result, one has to consider the following products:

$$m_6, f_6: \quad a_1^2; \quad a_2; \quad b_2$$

$$A_6: \quad a_1^3; \quad a_1 a_2; \quad a_3; \quad a_1 b_2; \quad b_3; \quad c_3.$$

(3.11)
3.2 Renormalization at two–loop order

3.2.1 General analysis

The loop contributions to $M_\pi, F_\pi$ and to the scattering amplitude $A(s, t, u)$ are divergent in the limit $d \to 4$. Using the notation (3.7), we are concerned here with the renormalization of the quantities $m_6, f_6$ and $A_6$. As is guaranteed by general theorems of renormalization theory [28], the divergent parts of $m_6$ and $f_6$ are mass independent in dimensional regularization. Likewise, the divergent part of $A_6$ is a polynomial in the external momenta and in $M^2$. The most general crossing symmetric polynomial arising at order $p^6$ is

$$F^6A_6^{\text{pol}} = A^{(1)}M^6 + A^{(2)}sM^4 + A^{(3)}s^2M^2 + A^{(4)}(t - u)^2M^2 + A^{(5)}s^3 + A^{(6)}s(t - u)^2$$

with six coefficients $A^{(1)}, \ldots, A^{(6)}$. Like $m_6$ and $f_6$, they receive contributions from two–loop graphs with $L_2$, one–loop graphs with one vertex from $L_4$ and tree graphs generated by $L_2 + L_4 + L_6$, see Eq. (3.11). The following analysis applies to each of the eight coefficients $m_6, f_6, A^{(1)}, \ldots, A^{(6)}$ separately. Denoting these coefficients generically as $Q$, we write

$$Q = Q_{\text{loop}} + Q_{\text{tree}}.$$  \hspace{1cm} (3.12)

Since $Q$ is part of a measurable quantity, it must of course be finite (and scale independent). The two components $Q_{\text{loop}}$ and $Q_{\text{tree}}$, on the other hand, are both divergent. Concentrating first on $Q_{\text{loop}}$, dimensional regularization produces for $m_6$ and $f_6$ the general form

$$Q_{\text{loop}} = \hat{T}_M \left\{ \hat{T}_M x(d) - \sum_{i=1}^{4} l_i(d)y_i(d) \right\},$$  \hspace{1cm} (3.13)

where $x(d), y_i(d)$ are dimensionless functions of $d$, finite at $d = 4$. (For the sake of clarity, we exhibit in this section the dependence of the low–energy couplings $l_i(d)$ on the space–time dimension $d$.) The same structure is found for the six coefficients $A^{(i)}$. We perform a Taylor series expansion,

$$x(d) = x_0 + x_1w + x_2w^2 + O(w^3),$$

$$y_i(d) = y_{i0} + y_{i1}w + y_{i2}w^2 + O(w^3) ; i = 1, \ldots, 4 ; w = \frac{d}{2} - 2$$

with real numbers $x_0, x_1, x_2, y_{i0}, y_{i1}, y_{i2}$. The tadpole integral $\hat{T}_M$ (2.17) and the low–energy constants $l_i(d)$ are both divergent as $w \to 0$. The Laurent expansion of the tadpole integral is displayed in (2.18). For the low–energy constants $l_i(d)$, we write

$$l_i(d) = \frac{\mu^{2w}}{(4\pi)^2} \left[ \frac{\gamma_i}{2w} + l_{i,r}^{\text{MS}}(\mu, w) \right],$$

$$\gamma_1 = \frac{1}{3}, \gamma_2 = \frac{2}{3}, \gamma_3 = -\frac{1}{2}, \gamma_4 = 2.$$  \hspace{1cm} (3.14)
For reasons already explained in Sect. 2 in the framework of the $N$–component $\phi^4$ theory, we have not expanded the renormalized couplings $l_{i,r}^{\text{MS}}(\mu, w)$ around $w = 0$. See comments after Eq. (2.24) and the discussion below.

Since there must not be any terms of the form

$$\frac{\ln M/\mu}{w}$$

in $Q_{\text{loop}}$, there are eight consistency conditions (for each of the eight coefficients $m_6, f_6, A^{(i)}$) of the type

$$x_0 = \frac{1}{4} \sum_{i=1}^{4} \gamma_i y_{i0} .$$

(3.15)

This absence of mass singularities in the divergences provides an extra check on our calculation. Using the equality (3.15) that relates one– and two–loop parameters, one gets (from now on, the summation convention is implied for $i = 1, \ldots, 4$)

$$Q_{\text{loop}} = \frac{\mu^4 w}{(4\pi)^4} \left\{ \frac{Q_2}{w^2} + \frac{Q_1}{w} + Q_0 + O(w) \right\} ,$$

$$Q_2 = -x_0 , Q_1 = x_1 - l_{i,r}^{\text{MS}}(\mu, w)y_{i0} - \frac{1}{2}\gamma_i y_{i1} ,$$

$$Q_0 = x_0 a(M/\mu)^2 + \left[ 2x_1 - l_{i,r}^{\text{MS}}(\mu)y_{i0} - \frac{1}{2}\gamma_i y_{i1} \right] a(M/\mu)$$

$$+ x_2 - l_{i,r}^{\text{MS}}(\mu)y_{i1} - \frac{1}{2}\gamma_i y_{i2} ,$$

where

$$l_{i,r}^{\text{MS}}(\mu) \equiv l_{i,r}^{\text{MS}}(\mu, 0) .$$

It is seen that the coefficient $c(M/\mu)$ in the Laurent expansion (2.18) of the tadpole integral $\hat{T}_M$ does not enter due to the relation (3.15).

The pole terms can now be absorbed by the tree–level contribution $Q_{\text{tree}}$ which is a certain combination (depending on the specific observable under consideration) of coupling constants in the general chiral lagrangian $\mathcal{L}_6$. Denoting this combination generically as $z(d)$, the expansion analogous to (3.14) is

$$Q_{\text{tree}}(d) \doteq z(d) = \frac{\mu^4 w}{(4\pi)^4} \left\{ -\frac{Q_2}{w^2} - \frac{Q_1}{w} + (4\pi)^4 z_r^{\text{MS}}(\mu) + O(w) \right\} .$$

(3.16)

The sum $Q_{\text{loop}} + Q_{\text{tree}}$ is finite and independent of the scale $\mu$ by construction. Taking the limit $d \rightarrow 4$ yields

$$\lim_{d \rightarrow 4} Q = \frac{Q_0}{(4\pi)^4} + z_r^{\text{MS}}(\mu) .$$

(3.17)
Recalling the scale independence of $Q$, $\tilde{T}_M$, $l_i(d)$ and of $z(d)$, one derives the renormalization group equation for the renormalized coupling constant $z^{\text{MS}}_r$:

$$\frac{dz^{\text{MS}}_r(\mu)}{d\mu} = \frac{2}{(4\pi)^4} \left[ 2x_1 - l^{\text{MS}}_{i,r}(\mu)y_0 - \gamma_i y_1 \right].$$  \hspace{1cm} (3.18)

Comparing Eqs. (2.19), (3.15) and (3.17), we recover the well-known fact [1, 23, 19] that the coefficient of the double logs can be determined solely from one-loop diagrams with a single vertex from $\mathcal{L}_4$.

### 3.2.2 Modified minimal subtraction

The above renormalization procedure corresponds to minimal subtraction, where powers of $\ln 4\pi + \Gamma'(1)$ occur in the final expressions, see (2.19). These terms can be absorbed by splitting from the renormalized couplings $l^{\text{MS}}_{i,r}(\mu)$ and $z^{\text{MS}}_r(\mu)$ appropriate finite pieces [29]. The procedure is based on the relation

$$\frac{\Gamma(1-w)}{(4\pi)^w} \exp w[\Gamma'(1) + \ln 4\pi] = \exp \sum_{n=2}^{\infty} \frac{\zeta(n)}{n} w^n,$$  \hspace{1cm} (3.19)

which shows that a simple factor is responsible for these terms. To remove them, one pulls out a factor $c^{2w}$ in the definition of the renormalized couplings in (3.14),

$$l_i(d) = \frac{(\mu c)^{2w}}{(4\pi)^2} \left\{ \frac{\gamma_i}{2w} + l^{c}_{i,r}(\mu, w) \right\},$$  \hspace{1cm} (3.20)

as a result of which $Q_{\text{loop}}$ in (3.13) becomes

$$Q_{\text{loop}} = (\mu c)^{4w} \left\{ (\mu c)^{-4w} \tilde{T}_M x(d) - (\mu c)^{-2w} \frac{\tilde{T}_M}{(4\pi)^2} \sum_{i=1}^{4} \left[ \frac{\gamma_i}{2w} + l^{c}_{i,r}(\mu, w) \right] y_i(d) \right\}.$$  \hspace{1cm} (3.21)

Pulling out in the analogous manner $c^{4w}$ in Eq. (3.16),

$$z(d) = \frac{(\mu c)^{4w}}{(4\pi)^4} \left\{ \cdots + (4\pi)^4 z^c_r(\mu) \right\},$$  \hspace{1cm} (3.22)

shows that these redefinitions amount to the change

$$\ln \frac{M}{\mu} \rightarrow \ln \frac{M}{\mu} - \ln c,$$

$$\left( l^{\text{MS}}_{i,r}(\mu), z^{\text{MS}}_r(\mu) \right) \rightarrow \left( l^{c}_{i,r}(\mu, 0), z^c_r(\mu) \right),$$  \hspace{1cm} (3.23)

in Eq. (3.17).

The traditional choice for $c$ in CHPT is [3]

$$\ln c = -\frac{1}{2} [\ln 4\pi + \Gamma'(1) + 1].$$

21
In this scheme, one uses the notation \(2\)

\[ l_i(d) = l'_i(\mu) + \frac{\mu^{2w} \gamma_i}{(4\pi)^2} \left\{ \frac{1}{2w} - \frac{1}{2} \ln 4\pi + \Gamma'(1) + 1 \right\} + O(w), \]

where

\[ l'_i(\mu) = \frac{1}{(4\pi)^2} l^c_{i,r}(\mu, 0) \]

according to (3.20). Similarly, we write

\[ z^r(\mu) = z^c(\mu) \]

for the above choice of the constant \(c\).

We have thus arrived at the final expressions that will be used for \(M_\pi, F_\pi\) and \(A(s, t, u)\):

\[ Q = \frac{1}{(4\pi)^4} \left\{ x_0 \left[ 1 + 2 \ln \frac{M}{\mu} \right]^2 + \left[ 2x_1 - \frac{1}{2} \gamma_i y_{i1} - (4\pi)^2 l^c_{i,r}(\mu) y_{i0} \right] \left( 1 + 2 \ln \frac{M}{\mu} \right) \right. \\
+ x_2 - \frac{1}{2} \gamma_i y_{i2} - (4\pi)^2 l^c_{i,r}(\mu) y_{i1} + (4\pi)^4 z^c(\mu) \} . \]  

(3.25)

The scale dependence of the renormalized couplings is

\[ \mu \frac{dz^c_r(\mu)}{d\mu} = \frac{2}{(4\pi)^4} \left[ 2x_1 - (4\pi)^2 l^c_{i,r}(\mu) y_{i0} - \gamma_i y_{i1} \right] , \]

\[ \mu \frac{dl^c_{i,r}(\mu)}{d\mu} = -\frac{\gamma_i}{(4\pi)^2} . \]

### 3.2.3 EOM and Laurent expansion of the coupling constants \(l_i\)

We include here a brief discussion of some technical aspects of the renormalization program at \(O(p^6)\). In Sect. 2, it was shown that the counterterms of \(\phi^4\) theory can be written in different forms using the EOM. Transforming from one set of counterterms to another leaves the functional \(Z_1\) unchanged and produces an additional local action of \(O(\bar{h}^2)\) that can always be absorbed by changing the coefficients of the counterterms in \(Z_2\).

The situation in CHPT is similar. Using the EOM of CHPT, both the lagrangians of \(O(p^4)\) and \(O(p^6)\) can take different forms. Since to \(O(p^6)\) the lagrangian \(L_6\) enters only at the classical solution, such a modification has no effect at all as far as \(L_6\) is concerned. The same is true for all quantities of \(O(p^4)\). However, the couplings in the lagrangian \(L_4\) also appear in one–loop and tree diagrams contributing at \(O(p^6)\). In this case, different forms of \(L_4\) lead to different results a priori.

As for the \(\phi^4\) theory in Sect. 2, the natural place to discuss those modifications is the generating functional of Green functions. Referring to a forthcoming paper \(27\) for an explicit proof, we present here only the final result. Lagrangians of \(O(p^4)\)
that differ by the EOM lead to generating functionals that differ by local actions of $O(p^6)$. Since those actions are of course chirally symmetric they can always be absorbed by a redefinition of the low-energy constants of $O(p^6)$.

If the low-energy constants are determined phenomenologically by comparison with experiment, the result is of course independent of the form of $L_4$. On the other hand, using a model for the constants of $O(p^6)$ like resonance saturation does not specify the form of $L_4$. Therefore, different forms of $L_4$ lead to different numerical results because the constants of $O(p^6)$ are by definition unchanged. For the $\pi\pi$ scattering amplitude, it turns out that the coefficients $b_1, \ldots, b_4$ are affected by this ambiguity while $b_5$ and $b_6$ are not modified. We come back in Sect. 5 to a numerical discussion of this ambiguity.

The second issue we want to address is the dependence of the low-energy constants $l_i$ of $O(p^4)$ on the dimension of space–time. In Eq. (3.14), we have defined functions $l_{i,r}^{\text{MS}}(\mu, w)$ that contain all non-singular pieces of the $l_i(d)$. These functions enter in the quantity $Q_1$ in $Q_{\text{loop}}$ and they are subtracted by the appropriate decomposition of $Q_{\text{tree}}$ in (3.16). As a consequence, only the coefficients $l_{i,r}^{\text{MS}}(\mu) = l_{i,r}(\mu, 0)$ appear in renormalized quantities.

Although this is a completely legal subtraction procedure, it is by no means obvious that this procedure can be applied consistently for all possible processes. In other words, the question is whether the low-energy constants of $O(p^6)$ can be decomposed as in Eq. (3.16) in a process–independent way such that only the $l_{i,r}^{\text{MS}}(\mu)$ appear in all observable quantities. To discuss this issue for the case of minimal subtraction, we expand the $l_i(d)$ up to first order in $w$:

$$l_i(d) = \frac{\mu^{2w}}{(4\pi)^2} \left[ \frac{\gamma_i}{2w} + l_{i,r}^{\text{MS}}(\mu) + \delta_i(\mu)w + O(w^2) \right].$$

The terms of $O(w^2)$ cannot contribute to $O(p^6)$ because the $l_i$ appear only in diagrams that are not more singular than $1/w$ (except for the divergent parts of the $l_i$ themselves). However, the coefficients $\delta_i(\mu)$ certainly do appear at $O(p^6)$. The subtraction procedure (3.16) leads to the following two questions:

- Do the coefficients $\delta_i(\mu)$ appear always in local contributions of $O(p^6)$ only?
- If yes, can they be absorbed into the coupling constants of $O(p^6)$ in a process–independent manner?

The crucial question is of course the first one. It can be shown [31, 27] that the terms involving the $\delta_i$ indeed take the form of local actions in the generating functional of $O(p^6)$, see also the analogous discussion in the framework of the $N$–component $\phi^4$ theory in Sect. 2. Although these contributions depend on the choice of the lagrangian of $O(p^4)$ (EOM), they can therefore always be absorbed in the low–energy constants of $O(p^6)$ in a process–independent way. Thus, the subtraction procedure (3.16) is a special case of a general method. It has already been used in [23, 24, 33].

4 Elastic $\pi\pi$ scattering to two loops
4.1 Pion mass

We consider the connected two-point function

\[ \Delta^{ik}(p^2) = i \int d^4x \, e^{-ip(x-y)} \langle 0 | T \phi^i(x) \phi^k(y) | 0 \rangle_{\text{conn}} \]  

(4.1)

at two-loop order. According to the formula (3.11), the topology of the graphs is the same as in \( O(N) \) theory, except for the term proportional to \( \phi^6 \). We may therefore again simplify the calculation by evaluating the tree and tadpole diagrams displayed in Fig. 3, with an appropriate choice for the propagators and for the interaction vertex, and to add the sunset diagram Fig. 2d, using the vertices that correspond to \( \mathcal{L}_2 \). Finally, the term from \( a_2 \) generates the butterfly diagram Fig. 6. Collecting these contributions, we find

\[ \Delta^{ik}(p^2) = \left\{ \frac{Z}{M^2_\pi - p^2} + R(p^2) \right\} \delta^{ik}, \]  

(4.2)

where

\[ M^2_\pi = M^2 + \frac{M^4}{F^2} \left\{ 2l_3 + \frac{T_M}{2M^2} \right\} + \frac{M^6}{F^4} \hat{T}_M \left\{ Q^M \hat{T}_M - \sum_{i=1}^{3} Q^M_i l_i \right\} + \frac{M^6 r_M}{F^6} + O(M^8), \]  

\[ Z = 1 - \frac{T_M}{F^2} + \frac{M^4}{F^4} \hat{T}_M \left\{ Q^Z \hat{T}_M - \sum_{i=1}^{3} Q^Z_i l_i \right\} + \frac{M^4 r_Z}{F^4} + O(M^6), \]  

(4.3)

where

\[ Q^M = \frac{1}{96} \left\{ 204 - 632w + 1263w^2 \right\} + O(w^3), \]  

\[ Q^M_1 = \frac{1}{2} \left\{ 28 - 30w + 31w^2 \right\} + O(w^3), \]  

\[ Q^M_2 = 8 - 10w + 11w^2 + O(w^3), \]  

\[ Q^M_3 = 3 - 4w + 4w^2 + O(w^3), \]  

(4.4)

and

\[ Q^Z = \frac{1}{96} \left\{ 96 - 464w + 1185w^2 \right\} + O(w^3), \]  

\[ Q^Z_1 = Q^M_1, Q^Z_2 = Q^M_2, Q^Z_3 = 2. \]  

(4.5)
The function $R(p^2)$ in the propagator is regular at $p^2 = M^2_\pi$. It is not needed in the following, and we no not display its explicit form \[24\] here. The quantities $r_M$ and $r_Z$ denote the counterterm contributions from the lagrangian $\mathcal{L}_6$. We note that $r_M$ renders the pion mass finite at two–loop order.

### 4.2 Pion decay constant

We consider the correlators of two pseudoscalar currents \[2\],

\[
G^{ik}(p^2) = i \int d^4 x e^{-ip(x-y)} \langle 0| T \bar{q}_x i\gamma_5 \tau^i q_x \bar{q}_y i\gamma_5 \tau^k q_y |0\rangle_{\text{conn}}, \quad \bar{q} = (\bar{u}, \bar{d})
\]

(4.6)
at two–loop order. Apart from the overall normalization, $G^{ik}$ differs from the two–point function $\Delta^{ik}$ only by terms generated by the low–energy constants $l_3$ and $l_4$ (and, of course, by the counterterms from $\mathcal{L}_6$). We find

\[
G^{ik}(p^2) = \left\{ \frac{G^2_\pi}{M^2_\pi - p^2} + R_\pi(p^2) \right\} \delta^{ik},
\]

(4.7)

where

\[
G^2_\pi = G^2 \left[ 1 + \frac{M^2}{F^2} \left\{ 2l_4 - 4l_3 - \frac{T_M}{M^2} \right\} + \frac{M^4}{F^4} \hat{T}_M \left\{ Q^G \hat{T}_M - \sum_{i=1}^4 Q^G_i l_i \right\} 
+ \frac{M^4}{F^4} \left\{ l_4^2 + 8l_4 l_3 + 4l_3^2 + r_G \right\} \right] + O(M^6),
\]

(4.8)

with

\[
G = 2FB, \quad Q^G = Q^Z, \quad Q^G_1 = Q^Z, \quad Q^G_2 = Q^Z, \quad Q_3^G = 2(8 - 7w + 7w^2) + O(w^3), \quad Q_4^G = 1 - w + w^2 + O(w^3).
\]

(4.9)

The counterterm contribution from $\mathcal{L}_6$ is denoted by $r_G$. It renders $G_\pi$ finite at two–loop order. The regular part $R_\pi$ is not needed in the following, and we therefore do not display it here.

The relation between the divergence of the axial current and the pseudoscalar density implies

\[
F_\pi M^2_\pi = \hat{m} G_\pi.
\]

(4.10)

The above expressions for the pion mass and for the residue $G_\pi$ therefore allow us to calculate the pion decay constant to two loops:

\[
F_\pi = F \left[ 1 + \frac{M^2}{F^2} \left\{ l_4 - \frac{T_M}{F^2} \right\} + \frac{M^4}{F^4} \left\{ r_F + \hat{T}_M \left( Q^F \hat{T}_M - \sum_{i=1}^4 Q^F_i l_i \right) \right\} \right] + O(M^6),
\]

(4.11)
Figure 7: Contributions to elastic $\pi\pi$ scattering in CHPT. The graphs displayed have a different topology than the ones occurring in $\phi^4$ theory. The filled box denotes a contribution proportional to the low-energy constant $l_3$. Graph $a_1$ is included by use of the formula indicated in Fig. 5, whereas graphs $a_2 \cdots a_5$ are not. These must be taken into account separately.

\[
\begin{align*}
Q_F^2 & = -\frac{1}{192}(240 - 656w + 1125w^2) + O(w^3), \\
Q_F^1 & = -\frac{1}{2}Q_C^1, \quad Q_F^2 = -\frac{1}{2}Q_C^2, \quad Q_F^3 = 2, \quad Q_F^4 = \frac{1}{2}Q_C^4.
\end{align*}
\]  
(4.12)

The counterterm contribution from $L_6$ is denoted by $r_F$. It renders $F_\pi$ finite at two-loop order.

4.3 The $\pi\pi$ scattering amplitude

We have discussed in Sect. 2 how one can simplify the calculation of the elastic scattering amplitude in the $N$-component $\phi^4$ theory by using the renormalized one-loop amplitude as a single nonlocal vertex. In case of CHPT, there are a few modifications to be taken into account:

1. As we discussed already in the case of the pion mass and pion decay constant, there are additional diagrams to be taken into account, see the formula (3.11). Some are displayed in Fig. 7. The first of these is taken care of by using the formula illustrated in Fig. 5, whereas the tadpole (Fig. $a_2$), the butterfly (Figs. $a_3,a_4$) and sunset diagram (Fig. $a_5$) have to be added by hand.

2. Since the effective lagrangian in CHPT has derivative interactions, the vertices entering the calculation have a nontrivial off-shell behaviour. This means that the one-loop amplitude entering the above formulae must first be calculated with the appropriate off-shell legs in $d$ dimensions. Since the relevant expression is not available in the literature, we display it in appendix B.

Needless to say that, despite the labour saving organization of the calculation that we just described, it is still rather long and tedious.

In analogy to what we have presented above, we might now display the amplitude in $d$ dimensions. Since the expression is rather long, we prefer to display only the renormalized final expression.
We use the notation
\( \langle \pi^d(p_4)\pi^c(p_3) \text{ out} | \pi^a(p_1)\pi^b(p_2) \text{ in} \rangle = \langle \pi^d(p_4)\pi^c(p_3) \text{ in} | \pi^a(p_1)\pi^b(p_2) \text{ in} \rangle + i(2\pi)^4 \delta^4(P_f - P_i) \left\{ \delta^{ab}\delta^{cd} A(s,t,u) + \text{cycl.} \right\} \),

where \( s, t, u \) are the usual Mandelstam variables, expressed in units of the physical pion mass squared \( M_\pi^2 \),

\[
s = (p_1 + p_2)^2 / M_\pi^2, \quad t = (p_3 - p_1)^2 / M_\pi^2, \quad u = (p_4 - p_1)^2 / M_\pi^2. \tag{4.13}
\]

Using these dimensionless quantities, the momentum expansion of the amplitude amounts to a Taylor series in

\[
x_2 = \frac{M_\pi^2}{F_\pi^2},
\]

where \( F_\pi \) denotes the physical pion decay constant. We find

\[
A(s,t,u) = x_2 [s - 1] + x_2^2 \left[ b_1 + b_2 s + b_3 s^2 + b_4 (t - u)^2 \right] + x_2^3 \left[ F^{(1)}(s) + G^{(1)}(s,t) + G^{(1)}(s,u) \right] + x_2^4 \left[ F^{(2)}(s) + G^{(2)}(s,t) + G^{(2)}(s,u) \right]
\]

\[
+ O(x_2^4), \tag{4.14}
\]

with

\[
F^{(1)}(s) = \frac{1}{2} \tilde{J}(s) \left( s^2 - 1 \right),
\]

\[
G^{(1)}(s,t) = \frac{1}{6} \tilde{J}(t) \left( 14 - 4 s - 10 t + s t + 2 t^2 \right),
\]

\[
F^{(2)}(s) = \tilde{J}(s) \left\{ \frac{1}{16\pi^2} \left[ \frac{503}{108} s^3 - \frac{929}{54} s^2 + \frac{887}{27} s - \frac{140}{9} \right] \right\} + b_1 (4 s - 3) + b_2 (s^2 + 4 s - 4) + \frac{b_3}{3} \left( 8 s^3 - 21 s^2 + 48 s - 32 \right) + \frac{b_4}{3} \left( 16 s^3 - 71 s^2 + 112 s - 48 \right),
\]

\[
+ \frac{1}{18} K_1(s) \left\{ 20 s^3 - 119 s^2 + 210 s - 135 - \frac{9}{16} s^2 \right\} + \frac{1}{32} K_2(s) \left\{ 3 s \pi^2 - 24 \right\} + \frac{1}{9} K_3(s) \left\{ 3 s^2 - 17 s + 9 \right\},
\]

\[
G^{(2)}(s,t) = \tilde{J}(t) \left\{ \frac{1}{16\pi^2} \left[ \frac{412}{27} - \frac{s}{54} (t^2 + 5 t + 159) - t \left( \frac{267}{216} t^2 - \frac{727}{108} t + \frac{1571}{108} \right) \right] \right\} + b_1 (2 - t) + \frac{b_2}{3} (t - 4) (2 t + s - 5) - \frac{b_3}{6} (t - 4)^2 (3 t + 2 s - 8)
\]

27
The loop functions $\bar{J}$ and $K_i$ are

\[
\begin{pmatrix}
\bar{J} \\
K_1 \\
K_2 \\
K_3
\end{pmatrix} = \begin{pmatrix}
0 & 0 & z & -4N \\
0 & z & 0 & 0 \\
0 & z^2 & 0 & 8 \\
Nzs^{-1} & 0 & \pi^2(Ns)^{-1} & \pi^2
\end{pmatrix} \begin{pmatrix}
h^3 \\
h^2 \\
h \\
-(2N^2)^{-1}
\end{pmatrix},
\]

and

\[
K_4 = \frac{1}{sz} \left( \frac{1}{2}K_1 + \frac{1}{3}K_3 + \frac{1}{N}\bar{J} + \frac{(\sqrt{s} - 6)s}{12N^2} \right),
\]

where

\[
h(s) = \frac{1}{N\sqrt{z}} \ln \frac{\sqrt{z} - 1}{\sqrt{z} + 1}, \quad z = 1 - \frac{4}{s}, \quad N = 16\pi^2.
\]

The functions $s^{-1}\bar{J}$ and $s^{-1}K_i$ are analytic in the complex $s$–plane (cut along the positive real axis for $s \geq 4$), and they vanish as $|s|$ tends to infinity. Their real and imaginary parts are continuous at $s = 4$. The coefficients $b_i$ in the polynomial part are given in appendix D.

Finally, we compare our result with the calculation performed in Ref. [9]. There are two basic differences between the two works. First, the present calculation is done in conventional chiral perturbation theory [2], whereas the authors of [9] work in a scenario in which the quark condensate may be small or zero [32] (generalized chiral perturbation theory). The second difference concerns the use of a lagrangian framework in the present approach, whereas S–matrix methods are applied in [9]: Starting from the expression for the amplitude at $O(p^4)$, unitarity allows one to determine the absorptive part at $O(p^6)$. One can then construct an amplitude that has exactly these absorptive parts. Of course, this procedure does not determine the polynomial part at this order. To illustrate, the diagrams of Fig. 7 do not have an absorptive part and can therefore not be determined in this manner. There are additional graphs of this kind. In the amplitude given in [9], these diagrams – and further polynomial contributions from graphs that do have an absorptive part – are lumped into a polynomial

\[
a_1 + a_2s + a_3s^2 + a_4(t-u)^2 + a_5s^3 + a_6s(t-u)^2 \quad (4.16)
\]
with a priori unknown coefficients that depend on the pion mass and on the low–
energy constants.

With this procedure, one does not have to work out individual Feynman dia-
grams, because only the total absorptive part at $O(p^6)$ – fixed through unitarity by
the amplitude at $O(p^4)$ – is needed. In addition, the expansion of the pion mass,
of the pion decay constant and of the wave function renormalization need not be
worked out at $O(p^6)$.

On the other hand, our result (4.14, 4.15) at $O(p^6)$ – obtained by painstakingly
evaluating in the manner described above all the Feynman diagrams generated by the
effective lagrangian (3.1) – reveals in addition to the findin gs of [9] the dependence
of the six coefficients $a_i (4.16)$ on the pion mass and on the low–energy constants of
both $O(p^4)$ and $O(p^6)$, see appendix D. In particular, we find that these coefficients
contain mass singularities that are known to be important numerically both at $O(p^4)$
[6, 2] and at $O(p^6)$ [19, 10] (see also Refs. [23, 24, 33]). Furthermore, the knowledge
of the mass dependence of the amplitude allows one to evaluate all quantities even
at unphysical values of the quark mass, and to confront the result with lattice
calculations [34]. This is not possible with the amplitude provided in Ref. [9].

We have checked that the amplitude of [9] (restricted to standard CHPT) and
the field theoretic calculation presented here agree as far as the absorptive part of
the amplitude and the general structure of the real part is concerned.

5 Numerical analysis

The elastic $\pi\pi$ scattering amplitude is expressed in terms of the external momenta,
the physical pion mass, the physical pion decay constant, and the coefficients $b_i$,

$$A(s, t, u) = f(p_1, \ldots, p_4; M_\pi, F_\pi; b_1, \ldots, b_6).$$

Before one can perform a numerical analysis, one thus needs an estimate of the
low–energy couplings $b_i$. The key relations (D.1) used in [10] for that purpose fix
the $b_i$ in terms of

- chiral logarithms $L = \frac{1}{16\pi^2} \ln \frac{M^2}{\mu^2}$,

- the low–energy couplings $l^r_1(\mu), \ldots, l^r_4(\mu)$ from $L_4$,

- the low–energy couplings $r^r_1(\mu), \ldots, r^r_6(\mu)$ generated by $L_6$.

For a given set of the low–energy constants $l^r_i$ it, therefore, suffices to estimate
the new couplings $r^r_i$ at $O(p^6)$. To achieve an order–of–magnitude estimate, we
use a method that has been successfully tested at $O(p^4)$ [2, 35]: We work out the
contributions from exchanges of heavy states to the scattering amplitude and assume
that these effects account for the bulk part in the low–energy couplings at $O(p^6)$. In
particular, we include the effect of meson resonance exchange with masses smaller
than 1 GeV, i.e., vector and scalar resonances. In addition, we also consider kaon
and eta contributions of $O(p^6)$. We describe in the following subsection the relevant
resonance couplings and work out the corresponding values for the $r_i$. 29
5.1 Resonance saturation

5.1.1 Vector meson exchange

At $O(p^4)$, the contributions of vector meson resonances to the low–energy constants are obtained most naturally with the tensor field representation of spin-1 mesons \[2, 36\]. The situation is different at $O(p^6)$ where the more common vector field formalism produces directly the relevant counterterm couplings, as observed previously for Compton scattering on pions and for $\gamma\gamma \rightarrow \pi\pi$ \[37, 23\]. We follow the same procedure here and comment later on the difference to the tensor field representation.

The relevant couplings of the vector field $\hat{V}_\mu$, representing the octet of vector mesons (the singlet does not contribute to $\pi\pi$ scattering), to the pseudoscalar mesons are given by \[36\]

$$L_V = - \frac{ig_V}{2\sqrt{2}} \left\langle \hat{V}_{\mu\nu}[u^\mu, u^\nu] \right\rangle + f_\chi \left\langle \hat{V}_\mu[u^\mu, \chi_-] \right\rangle$$

(5.1)

with real dimensionless coupling constants $g_V, f_\chi$. We switch to chiral $SU(3)$ here (and also in the next subsection for the discussion of scalar exchange) to determine both couplings $g_V, f_\chi$ from vector meson decays. From the Lagrangian (5.1) one finds that the combination

$$g_V + 2\sqrt{2}f_\chi \frac{M_1^2 + M_2^2}{M_V^2}$$

determines the amplitude for the decay of a vector meson into two pseudoscalars. From the experimental widths for $\rho \rightarrow \pi\pi$ and $K^* \rightarrow K\pi$ one obtains $g_V f_\chi < 0$ with

$$g_V = 0.09, \quad f_\chi = -0.03,$$

(5.2)

if we define $g_V$ to be positive. V exchange on the basis of (5.1) gives rise to three types of contributions proportional to $g_V^2$, $g_V f_\chi$ and $f_\chi^2$, respectively. With

$$a_V = \frac{g_V^2 F_\pi^2}{M_V^2} = 1.2 \cdot 10^{-4}$$

$$b_V = \frac{4\sqrt{2}g_V f_\chi F_\pi^2}{M_V^2} = -2.2 \cdot 10^{-4}$$

$$c_V = \frac{32f_\chi^2 F_\pi^2}{M_V^2} = 4.2 \cdot 10^{-4},$$

using $M_V = M_\rho$ for the numerical values, we obtain the following V exchange contributions to the low–energy constants $r_i$:

$$r_1^V = -16a_V - 16b_V - 4c_V$$

$$r_2^V = 20a_V + 16b_V + 3c_V$$

$$r_3^V = -7a_V - 3b_V$$

(5.3)
\[ r^V_4 = a_V + b_V \]
\[ r^V_5 = \frac{3}{4} a_V \]
\[ r^V_6 = \frac{1}{4} a_V . \]

In the tensor field representation, there is a single coupling (relevant for \( \pi \pi \) scattering) between vector mesons and pseudoscalars at lowest order \([2, 33]\). Up to normalization, the corresponding coupling constant is given by \( g_V \). For instance, expanding the \( \rho \) exchange amplitude of Ref. [2] to \( O(p^6) \) is equivalent to (5.3) with \( b_V = c_V = 0 \). Higher–order couplings can only contribute at \( O(p^6) \) through interference with the \( g_V \) amplitude. Thus, the contributions involving \( f_2^\chi \) that appear naturally in the vector field formalism would have to be added by hand in the tensor field representation as explicit local counterterms.

### 5.1.2 Scalar meson exchange

To estimate the effect of scalar resonances for the \( r_i \), we take the lowest–order lagrangian of Ref. [35] for octet and singlet scalar fields \( S, S_1 \),

\[ \mathcal{L}_S = c_d \langle Su^\mu u_\mu \rangle + c_m \langle S\chi_+ \rangle + \tilde{c}_d S_1 \langle u^\mu u_\mu \rangle + \tilde{c}_m S_1 \langle \chi_+ \rangle , \]

and expand the resonance exchange amplitudes up to \( O(p^6) \). The resulting scalar contributions to the \( r_i \) are:

\[ r^S_1 = 0 \]
\[ r^S_2 = \frac{8 F_\pi^2}{3 M_S^2} (c_m - c_d)^2 + \frac{16 F_\pi^2}{M_S^4} (\tilde{c}_m - \tilde{c}_d)^2 \]
\[ r^S_3 = \frac{8 F_\pi^2}{3 M_S^2} c_d (c_m - c_d) + \frac{16 F_\pi^2}{M_S^4} \tilde{c}_d (\tilde{c}_m - \tilde{c}_d) \]
\[ r^S_4 = 0 \]
\[ r^S_5 = \frac{2 F_\pi^2}{3 M_S^2} c_d^2 + \frac{4 F_\pi^2}{M_S^4} \tilde{c}_d^2 \]
\[ r^S_6 = 0 . \]

Note that the physical pion mass and the physical pion decay constant receive contributions from scalar exchange as well.

For the numerical evaluation we use the same values for masses and coupling constants as in Ref. [35]:

\[ M_S = M_{S_1} = 983 \text{ MeV} \]
\[ c_m = 42 \text{ MeV} , \quad c_d = 32 \text{ MeV} \]
\[ \tilde{c}_m = c_m / \sqrt{3} , \quad \tilde{c}_d = c_d / \sqrt{3} . \]
5.1.3 Kaon and eta contributions

In the framework of chiral $SU(3)$, $K$ and $\eta$ mesons contribute at $O(p^4)$ to $\pi\pi$ scattering via loop diagrams. Restricting the scattering amplitude of $O(p^4)$ evaluated in chiral $SU(3)$ [9] to $SU(2) \times SU(2)$ by an expansion in inverse powers of the strange quark mass, one arrives at the following contributions to the $r_i$ due to $K$ and $\eta$ mesons:

$$r^K_1 = \frac{31 F^2}{5760 \pi^2 M_K^2}$$
$$r^K_2 = -\frac{11 F^2}{2304 \pi^2 M_K^2}$$
$$r^K_3 = -\frac{29 F^2}{7680 \pi^2 M_K^2}$$
$$r^K_4 = -\frac{F^2}{2560 \pi^2 M_K^2}$$
$$r^K_5 = \frac{23 F^2}{15360 \pi^2 M_K^2}$$
$$r^K_6 = \frac{F^2}{15360 \pi^2 M_K^2}.$$

(5.6)

5.1.4 Numerical values of the $r_i$

Putting the various contributions of the previous subsections together, we obtain the following numerical estimates for what we shall call the resonance contributions to the low–energy constants of $O(p^6)$:

$$r^R_1 = -0.6 \cdot 10^{-4}$$
$$r^R_2 = 1.3 \cdot 10^{-4}$$
$$r^R_3 = -1.7 \cdot 10^{-4}$$
$$r^R_4 = -1.0 \cdot 10^{-4}$$
$$r^R_5 = 1.1 \cdot 10^{-4}$$
$$r^R_6 = 0.3 \cdot 10^{-4}.$$

(5.7)

These values are the ones used in Ref. [10]. They indicate an $O(p^6)$ version of vector meson dominance: Despite some strong cancellations (especially for $r^V_1$, $r^V_2$), all six constants $r^R_i$ are dominated by the exchange of vector mesons.$^5$

Of course, the constants $b_i$ become scale dependent if we now replace the $r^R_i(\mu)$ by the above $r^R_i$. At $O(p^4)$, the empirically observed resonance saturation of low–energy constants amounts to the statement [35] that the resonance contributions describe the phenomenologically determined coupling constants quite well for a scale $\mu$ between 500 MeV and 1 GeV. Pending a more refined analysis along the lines

$^5$ Other estimates of the low–energy constants of $O(p^6)$ can be found in Refs. [38].
discussed below, we assume for the time being that the same approximation is meaningful also at $O(p^6)$. Of course, only observables that are relatively insensitive to scale changes in the range mentioned can be estimated in a reasonable manner in this way.

5.2 The constants $b_i$

Together with the couplings $l'_i$ at $O(p^4)$, the estimates (5.7) allow one to work out the constants $b_1, \ldots, b_6$. We used in Ref. [10] values for the $l'_i$ that were determined mainly from an $O(p^4)$ analysis [2], with additional input from a dispersive estimate of higher–order effects in $K_{l4}$ decays [21]. As emphasized in our previous paper, all those determinations were faced with the problem that the $l_i$ are mass independent, whereas the physical quantities, from which the $l'_i$ were determined, include quark mass effects. We will illustrate below the relevance of those quark mass effects by example.

With the scale–independent couplings $\bar{l}_i$ (cf. App. D) found in [2, 21],

\[
\begin{align*}
\bar{l}_1 &= -1.7 , \quad \bar{l}_2 = 6.1 , \\
\bar{l}_3 &= 2.9 , \quad \bar{l}_4 = 4.3 , 
\end{align*}
\]

(5.8)

and with the constants $r^R_i$ in (5.7), one arrives\footnote{As in Ref. [10], we use $F_\pi = 93.2$ MeV, $M_\pi = 139.57$ MeV.} at the $b_i$ displayed in table 1. There, we have split the contributions to the $b_i$ into one–loop and two–loop effects. Furthermore, we indicate separately the contributions from the $r^R_i$. The values shown correspond to the scale $\mu = 1$ GeV ($\mu = 500$ MeV in brackets). (We display the values to two digits for ease of reproduction of the numbers.) Below we refer to the $b_i$ in this table as set I. The following remarks are in order.

Table 1: The constants $b_i$ (set I). We use Eqs. (5.7,5.8) as input to evaluate $b_i$ from Eq. (D.1). The numbers correspond to $\mu = 1$ GeV, in brackets we display the corresponding values at $\mu = 500$ MeV.

|       | 1-loop | 2-loops, $r_i=0$ | from $r^R_i$ | total   |
|-------|--------|-----------------|-------------|---------|
| $10^2b_1$ | -7.34  | -1.76 (-1.82)   | -0.01       | -9.11 (-9.17) |
| $10^2b_2$ | 6.74   | 2.07 (2.12)     | 0.03        | 8.84 (8.89)    |
| $10^3b_3$ | -0.84  | -3.05 (-3.43)   | -0.38       | -4.27 (-4.65)  |
| $10^3b_4$ | 5.56   | 1.72 (1.71)     | -0.22       | 7.05 (7.04)     |
| $10^4b_5$ | 1.22 (1.24) | 1.10       | 2.32 (2.34)   |
| $10^4b_6$ | 1.19 (0.77) | 0.30       | 1.49 (1.07)   |
The change induced by $\mu = 1$ GeV $\to \mu = 500$ MeV is of the same order or bigger than the contributions from $r_i^R$ (see also table 3), with the possible exception of $b_4$.

Besides the scale dependence, there is yet another source of uncertainty that has to do with using the EOM in the lagrangian of $O(p^4)$. As discussed in Sects. 2 (for $\phi^4$) and 3 (for CHPT), this ambiguity can always be resolved by a redefinition of the coupling constants of $O(p^6)$ – physical observables are of course unaffected. Although this is a completely general result for the generating functional to $O(p^6)$ [27], we nevertheless face a practical problem here because our estimates of the $r_i^R$ via resonance exchange are not only scale independent but they also make no reference to the form of the lagrangian of $O(p^4)$. We have checked that using the $O(p^4)$ lagrangians of either Ref. [2] or of Ref. [39] induces a change in $b_{1,2,3,4}$ by an amount that is smaller than the change due to a different choice of scale. The constants $b_{5,6}$ are unaffected by this procedure.

The main uncertainties in the $b_i$ stem from the couplings of $O(p^4)$, as we now illustrate. In table 4, we have displayed the contributions from $\bar{l}_i$ to $b_i$ at one-loop order. They are at least an order of magnitude bigger than the ones from the $r_i^R$ – therefore, uncertainties in the latter are swamped by uncertainties in the $\bar{l}_i$. One of these are quark mass effects, mentioned above. To illustrate these, we repeat the analysis of Ref. [2] to fix $\bar{l}_1, \bar{l}_2$ from the $D$–wave scattering lengths $a_0^2, a_2^2$, but now to $O(p^6)$. Keeping $\bar{l}_3, \bar{l}_4$ fixed, the experimental values [40] given in table 4 lead to

$$\bar{l}_1 = -1.5 \quad \bar{l}_2 = 4.5$$

(5.9)

if $\bar{l}_3, \bar{l}_4$ from (5.8) are used as input. The $b_i$ that result from this exercise are displayed in table 3 and referred to as set II in the following. Since $b_{1,2}$ do not depend on $\bar{l}_2$, they remain largely unaffected, whereas the change in $b_{3,4}$ is seen to be substantial. The values (5.9) should be compared with the values obtained at $O(p^4)$, $\bar{l}_1 = -2.3$ and $\bar{l}_2 = 6.0$, from the same input [2]. Values similar to (5.9) were found in [20] comparing a Roy equation fit to our $p^6$ amplitude [10].

Similar effects are expected from changes in $\bar{l}_4$ that does contribute substantially to $b_{1,2}$. As we already mentioned in our previous work [19], a more detailed analysis is therefore needed to obtain reliable values for the $\bar{l}_i$, consistent with an analysis at $O(p^6)$, and, at the same time, values for the $b_i$ with error bars attached. Such an analysis is under way [41].

This brings us to the work of Ref. [18] who find from dispersion sum rules the
Table 2: Contributions from the individual $\bar{l}_i$ in Eq. (5.8) to the constants $b_i$ in the one-loop approximation. Note that $b_5, b_6$ start at two-loop order.

|          | $\bar{l}_1$ | $\bar{l}_2$ | $\bar{l}_3$ | $\bar{l}_4$ | analytic | total  |
|----------|-------------|-------------|-------------|-------------|----------|--------|
| 1-loop   |             |             |             |             |          |        |
| $10^2 b_1$ | -1.44       | 0           | -0.92       | -5.44       | 0.46     | -7.34  |
| $10^2 b_2$ | 1.44        | 0           | 0           | 5.44        | -0.14    | 6.74   |
| $10^3 b_3$ | -3.59       | 6.44        | 0           | 0           | -3.69    | -0.84  |
| $10^3 b_4$ | 0           | 6.44        | 0           | 0           | -0.88    | 5.56   |

Table 3: The constants $b_i$ (set II). We use Eqs. (5.7,5.3) as input to evaluate $b_i$ from Eq. (D.1). The numbers correspond to $\mu = 1$ GeV; in brackets we display the corresponding values at $\mu = 500$ MeV.

|          | 1-loop | 2-loops, $r_i=0$ | from $r_i^R$ | total  |
|----------|--------|-----------------|--------------|--------|
|          |        |                 |              |        |
| $10^2 b_1$ | -7.17  | -1.44 (-1.62)   | -0.01        | -8.63  (-8.80) |
| $10^2 b_2$ | 6.57   | 1.41 (1.71)     | 0.03         | 8.01 (8.31)  |
| $10^3 b_3$ | -2.11  | -0.14 (-1.85)   | -0.38        | -2.63 (-4.34) |
| $10^3 b_4$ | 3.87   | 1.17 (1.20)     | -0.22        | 4.82 (4.85)  |
| $10^4 b_5$ | -1.47  | (-0.22)         | 1.10         | -0.37 (0.88) |
| $10^4 b_6$ | 0.53   | (0.42)          | 0.30         | 0.83 (0.72)  |

Values

$$
\begin{align*}
  b_3 &= (-3.7 \pm 2.4) \cdot 10^{-3} \\
  b_4 &= (4.8 \pm 0.3) \cdot 10^{-3} \\
  b_5 &= (1.4 \pm 0.6) \cdot 10^{-4} \\
  b_6 &= (1.0 \pm 0.1) \cdot 10^{-4}
\end{align*}
$$

Within the error bars quoted, these values are consistent with our set II. The theoretical framework used in [18] does not allow these authors to determine $b_{1,2}$ – rather, these quantities can in principle be determined from precise data on elastic $\pi\pi$ scattering, allowing then a determination of the size of the quark condensate in the chiral limit.

vi) Recently, Wanders has also extracted the $b_{3,4,5,6}$ using crossing-symmetric sum rules [11]. Taking the $O(p^4)$ expressions for $b_1, b_2$ as input, he finds that at
three of the $b_i$ are only weakly sensitive to the choice of the energy separating high- and low-energy components in the sum rules. The resulting values (for the interpretation of the errors we refer to \[11\])

\[
\begin{align*}
&b_3 = (-2.55 \pm 0.20) \cdot 10^{-3} \\
&b_4 = (4.55 \pm 0.15) \cdot 10^{-3} \\
&b_6 = (0.92 \pm 0.03) \cdot 10^{-4}
\end{align*}
\]

are consistent with our set II and with the values \((5.10)\) of Knecht et al. \[18\].

### 5.3 Threshold parameters and phase shifts

To compare the theoretical amplitudes with data on $\pi\pi$ scattering, one expands the combinations with definite isospin in the $s$-channel

\[
\begin{align*}
T^0(s, t) & = 3A(s, t, u) + A(t, u, s) + A(u, s, t) \\
T^1(s, t) & = A(t, u, s) - A(u, s, t) \\
T^2(s, t) & = A(t, u, s) + A(u, s, t)
\end{align*}
\]

into partial waves,

\[
T^I(s, t) = 32\pi \sum_{l=0}^{\infty} (2l + 1) P_l(\cos \theta) t^I_l(s) .
\]

Unitarity implies that in the elastic region $4 \leq s \leq 16$ the partial wave amplitudes $t^I_l$ are described by real phase shifts $\delta^I_l$,

\[
t^I_l(s) = \left( \frac{s}{s - 4} \right)^{1/2} \frac{1}{2i} \{ e^{2i\delta^I_l(s)} - 1 \} .
\]

The behaviour of the partial waves near threshold is of the form

\[
\text{Re } t^I_l(s) = q^{2l} \{ a^I_l + q^2 b^I_l + O(q^4) \} ,
\]

with $q$ the center–of–mass three–momentum of the pions, i.e. $s = 4(1 + q^2/M^2_\pi)$. The threshold parameters $a^I_l$, $b^I_l$ are referred to as scattering lengths and slope parameters, respectively.

In table 4, we compare the threshold parameters of the low partial waves with experimental results. We emphasize once more that we do not consider the values for either set I or set II as the definitive results of $O(p^6)$. To arrive at such results, a more detailed analysis based on the Roy–equation approach is under way \[41\]. With this caveat in mind, we notice that the $\bar{l}_1$, $\bar{l}_2$ from the $D$–wave scattering lengths (set II) tend to improve the agreement with experiment with the possible exception of the $S$–wave scattering lengths $a_0^0$, $a_2^0$. We comment on the experimental determinations of scattering lengths below. We also note that the ambiguity in scale or in the choice of the lagrangian of $O(p^4)$ affects $a_0^0$ in the third digit only.

\footnote{We recall our normalization of the Mandelstam variables in \[4.13\].}
Table 4: Threshold parameters in units of $M_{\pi^+}$. The values of $O(p^4)$ and $O(p^6)$ (set I) correspond to $\bar{l}_1 = -1.7, \bar{l}_2 = 6.1, \bar{l}_3 = 2.9, \bar{l}_4 = 4.3$. For $O(p^6)$ (set II), $\bar{l}_1 = -1.5, \bar{l}_2 = 4.5$ were extracted from the $D$–wave scattering lengths ($\bar{l}_3, \bar{l}_4$ unchanged). The fourth column shows the values obtained taking only the contributions from the $k_i$ defined in App. D. We set $\mu = 1 \text{ GeV}$ and take the $r_i^f(1 \text{ GeV})$ from (5.7). The experimental values are from Ref. [40].

|        | $O(p^2)$ | $O(p^4)$ | $O(p^6)$ set I | $O(p^6)$ set II | experiment |
|--------|----------|----------|----------------|-----------------|------------|
| $a_0^0$ | 0.16     | 0.20     | 0.213          | 0.217           | 0.26 ± 0.05 |
| $b_0^0$ | 0.18     | 0.25     | 0.279          | 0.275           | 0.25 ± 0.03 |
| $-10a_0^2$ | 0.45     | 0.42     | 0.407          | 0.413           | 0.28 ± 0.12 |
| $-10b_0^2$ | 0.91     | 0.73     | 0.69           | 0.72            | 0.82 ± 0.08 |
| $10a_1^1$ | 0.30    | 0.37     | 0.40           | 0.40            | 0.38 ± 0.02 |
| $10^2b_1^1$ | 0       | 0.48     | 0.78           | 0.79            | 0.54       |
| $10^2a_2^0$ | 0       | 0.18     | 0.30           | 0.27            | input      |
| $10^4a_2^2$ | 0       | 0.21     | 0.34           | 0.23            | input      |

In Figs. 8, 9 we plot the phase shift difference $\delta_0^0 - \delta_1^1$ and the $I = 2$ $S$–wave phase shift $\delta_2^0$ as functions of the center–of–mass energy and compare with the available low–energy data. The phase shifts correspond to the amplitudes of $O(p^2)$, $O(p^4)$ and $O(p^6)$ (for both sets I and II), respectively. The two–loop phase shifts describe the $K_{\pi\pi}$ data quite well for both sets of $\bar{l}_i$, with a small preference for set I. The $I = 2$ $S$–wave, on the other hand, seems to prefer set II.

There is an interesting lesson we can draw from our amplitude concerning the extraction of threshold parameters from phase shift data. Looking at Fig. 8 we observe that the $p^6$ amplitude (set I) describes the data almost perfectly. On the other hand, the value for the scattering length $a_0^0$ in table 4 is 0.217 for set I, quite a bit smaller than the 0.26 from Ref. [40] and even smaller than the 0.28 from Ref. [42].

To put these differences into perspective, we consider the effective range approximation for $S$–wave scattering [44],

$$q \cot \delta_0^f = \frac{M_{\pi}}{a_0^0} + \frac{1}{2} r_0^f q^2,$$

with $r_0^f$ the effective range. In terms of the threshold parameters defined in (5.15),

$$\frac{M_{\pi}}{a_0^0} = \frac{1}{2} r_0^f q^2.$$
the effective range is given by

$$r_0^I = \frac{1}{M_\pi a_0^I} - \frac{2M_\pi b_0^I}{(a_0^I)^2} - \frac{2a_0^I}{M_\pi}. \quad (5.17)$$

A similar formula can be used for $\delta_1^I$ when we replace $(a_0^I, b_0^I)$ by $(q^2a_1^I, q^2b_1^I)$.

In Ref. [42], the following approximation was used to extract the scattering length $a_0^0$ from the measured phase shifts:

$$\sin 2(\delta_0^0 - \delta_1^1) = 2\sqrt{1 - \frac{4}{s}(a_0^0 + q^2b)}. \quad (5.18)$$

In addition, a relation between $a_0^0$ and $b$ attributed to Basdevant et al. [45] was employed for a one–parameter fit to the data.

In Fig. 10, we compare the phase shift difference $\delta_0^0 - \delta_1^1$ from the full two–loop calculation (set I) with the effective range formula (5.16) and with the approximation (5.18) used by Rosselet et al. [42]. For the effective range approximation, we have used the threshold parameters corresponding to the CHPT amplitude (set I in table 4). In the curve based on (5.18) we have also used $a_0^0 = 0.217$ and the above mentioned relation [45] between $a_0^0$ and $b$.  

---

Figure 8: Phase shift difference $\delta_0 - \delta_1$ at $O(p^2)$, $O(p^4)$ and $O(p^6)$ (set I and II). The data points are from Ref. [42].

---

### Table 4

| Parameter | Value |
|-----------|-------|
| $a_0^0$   | 0.217 |
| $b$       |       |
Figure 9: Phase shift $\delta^2_0$ at $O(p^2)$, $O(p^4)$ and $O(p^6)$ (set I and II). The data points are from Ref. [43].

The obvious conclusion is that both the effective range approximation and the approximation used in Ref. [42] deviate from CHPT to $O(p^6)$ already at comparatively low energies. Fig. 10 also shows why the scattering length obtained in Ref. [42] is bigger than the CHPT value. It is hardly necessary to emphasize that the phase shift from CHPT is superior to both approximations on all accounts.

6 Conclusions

In this paper we have presented the calculation of elastic pion–pion scattering to sixth order in the low–energy expansion of QCD. The main part has been devoted to explaining the technical aspects of the results given in [10].

We first developed the loop expansion and the renormalization procedure for the generating functional of Green functions at the one– and two–loop level in the $N$–component $\phi^4$ theory. We concentrated on issues that are relevant for the corresponding CHPT calculation. In particular, we have discussed the dependence on the renormalization scheme and the impact of the EOM. Using the EOM, the counterterms in $\phi^4$ theory can be written in different ways. We demonstrated explicitly that different choices are equivalent in the sense that the differences can always be
absorbed into the higher–order parameters. We discussed a method for calculating two–loop diagrams by treating the renormalized one–loop amplitude as a nonlocal vertex. This approach turns out to be especially useful for the more involved CHPT calculation.

For the case of CHPT, we then performed the corresponding calculations for the pion mass, the pion decay constant and the $\pi\pi$ scattering amplitude. The renormalization of these quantities to $O(p^6)$ was discussed in detail for both minimal subtraction and for the modified minimal subtraction scheme that we actually used. In analogy to $\phi^4$ theory, the role of the EOM in relating different forms of the chiral lagrangian was discussed. We also commented on the Laurent expansion in $d−4$ of the coupling constants of $O(p^4)$.

We determined the complete dependence of $M_\pi$, $F_\pi$ and the scattering amplitude on the quark masses. As in previous full two–loop calculations [23, 24, 33], this dependence is both of theoretical interest and of numerical relevance. The analytical expressions for the scattering amplitude and for the threshold parameters were given.

For the numerical analysis of $\pi\pi$ scattering, we derived estimates of the low–energy constants of $O(p^6)$ on the basis of meson resonance exchange including kaon and eta contributions. These estimates turn out to be dominated by vector meson contributions. Although there are considerable uncertainties in this simple version
of resonance saturation, the overall size of the constants of \( O(p^6) \) is such that many quantities are relatively immune to those uncertainties. This is especially the case for the \( S \)-waves. However, for the higher partial waves and for a systematic error analysis in general a more sophisticated approach is needed. Such an analysis based on Roy equations is under way \[41\]. A similar approach has already been used in the dispersive treatment of the scattering amplitude to two-loop order \[9, 18\].

The major uncertainties for a numerical analysis reside in the low-energy constants of \( O(p^4) \). To illustrate this uncertainty, we have presented results both for the standard set of those constants \[2, 21\] and for a second set where \( \bar{l}_1, \bar{l}_2 \) are determined from the \( D \)-wave threshold parameters to \( O(p^6) \) as given in this paper. In this case, even the \( S \)-waves are sensitive to which set of constants is used. This makes it all the more necessary to perform an analysis where all the constants are determined on the basis of \( O(p^6) \) quantities that include, in particular, quark mass effects.

We have also presented numerical results for the phase shifts including the combination that can be measured directly in \( K_{e4} \) decays. For this particular example, we demonstrated that approximations like the effective range expansion may deviate from the CHPT predictions already at relatively low energies. We have emphasized the problems of extracting threshold parameters on the basis of such approximations from phase shift data.

The results obtained here for the \( \pi \pi \) scattering amplitude to \( O(p^6) \) will be used for a systematic analysis \[11\] of the available experimental data. In addition, they will be the basis for significant tests of QCD at low energies together with forthcoming measurements of \( \pi \pi \) scattering near threshold in \( K_{e4} \) decays and in pionium decay \[46\].

A Fish and sunset diagrams

A.1 Notation

We use the notation

\[
\langle \ldots \rangle = \int \frac{d^dl_1}{i(2\pi)^d} (\ldots) , \quad \langle\langle \ldots \rangle\rangle = \int \frac{d^dl_1}{i(2\pi)^d} \int \frac{d^dl_2}{i(2\pi)^d} (\ldots) ,
\]

together with

\[
w = \frac{d}{2} - 2.
\]
Furthermore, as only one mass parameter occurs in this appendix, we put everywhere $M^2 = 1$. It is straightforward to supplement the quantities below with the relevant mass factors.

The loop function $J(s)$ in $d$ dimensions is

$$J(s) = \frac{1}{(1 - l_1^2)(1 - (l_1 - p)^2)} = \frac{1}{(4\pi)^{2+w}} \Gamma(-w) \int_0^1 dx \left(1 - sx(1 - x)^w\right) ; \quad p^2 = s . \quad (A.1)$$

For $J$ one has the dispersive representation

$$J(s) = \int_{-\infty}^\infty \frac{[dx]}{x - s} ; \quad -1.5 < w < 0 , \quad (A.2)$$

where the measure is

$$[dx] = \frac{\Gamma(3/2)}{(4\pi)^2 + w} \left(\frac{x}{4}\right)^w \left(1 - \frac{x}{4}\right)^{\frac{1}{2}+w} dx . \quad (A.3)$$

It is often convenient to split off the divergent part through

$$J(s) = J(0) + \tilde{J}(s) ,$$

$$J(0) = \frac{1}{(4\pi)^{2+w}} \Gamma(-w) ,$$

$$\tilde{J}(s) = s \int_{-\infty}^\infty \frac{[dx]}{x(x - s)}$$

$$\overset{d\rightarrow4}{=} \frac{1}{16\pi^2} \left[\sigma \ln \frac{\sigma - 1}{\sigma + 1} + 2\right] ; \quad \sigma = (1 - 4/s)^{\frac{1}{2}} . \quad (A.4)$$

The constant $J(0)$ is related to $\hat{T}_M$, used in the text, via $\hat{T}_M = -J(0)$ taking into account that $M = 1$ in this appendix.

### A.2 The fish diagram

The scalar integral for the fish diagram has the form

$$V(s) = \left\langle \left\langle \prod_{i=1}^4 \frac{1}{D_i} \right\rangle \right\rangle$$

with

$$D_1 = 1 - l_1^2 , \quad D_2 = 1 - (Q - l_1)^2 ,$$

$$D_3 = 1 - l_2^2 , \quad D_4 = 1 - (l_2 + l_1 - p_1)^2 ,$$

$$Q = p_1 + p_2 , \quad p_1^2 = p_2^2 = 1 , \quad Q^2 = s .$$
We evaluate this integral in two steps: First, we identify that part of the function $V(s)$ that stays finite as $d \to 4$ by subtracting the divergent subintegral and by removing the remaining overall divergence. In the second step, we determine the finite part by evaluating its absorptive part along the cut in the variable $s$ and by then constructing an analytic function that has the same absorptive part and the same behaviour at $s \to 0, -\infty$.

Subtractions

Integration over $l_2$ generates the loop function $J(\bar{t}), \bar{t} = (p_1 - l_1)^2$. We subtract the divergence in this subdiagram by using the decomposition (A.4) and obtain

$$
V(s) = J(0)J(0) + V_1(s),
$$

$$
V_1(s) = \int_4^\infty \frac{dx}{x} \left( \frac{\bar{t}}{D_1D_2(x-t)} \right).
$$

(A.5)

$V_1$ is still divergent at $d = 4$. Using the Feynman parametrization

$$
\frac{1}{D_1D_2(x-t)} = \int_0^1 \frac{2x_2dx_1dx_2}{[(x_1D_1 + (1-x_1)D_2)x_2 + (x-t)(1-x_2)]^3},
$$

integrating first over $l_1$ and then by parts in $x_1$ shows that $V_1$ can be made finite by subtracting its value at $s = 0$,

$$
V_1(s) = V_1(0) + \mathcal{V}_1(s) ; \lim_{s \to -\infty} \frac{\mathcal{V}_1(s)}{s} = 0.
$$

$V_1(0)$ can be evaluated by methods similar to the ones used below for the sunset integral.

The finite part $\mathcal{V}_1(s)$

To evaluate the absorptive part of $\mathcal{V}_1(s)$, we invoke unitarity [17]:

$$
\text{Im}V(s) = J(0)\text{Im}J(s) + \text{Im}\mathcal{V}_1(s)
$$

$$
= \frac{(2\pi)^{2w+4}}{2} \int d\mu(l)d\mu(l')\delta^{(d)}(Q-l-l')J(\bar{t}) ,
$$

where $d\mu$ is the Lorentz invariant measure in $d$ dimensions,

$$
d\mu(l) = \frac{d^{2w+4}l}{2(2\pi)^{2w+4}l^0}, \quad l^0 = \sqrt{1+\bar{t}^2} ,
$$

(A.6)

We write again $J(\bar{t}) = J(0) + \bar{J}(\bar{t})$ and use

$$
\frac{(2\pi)^{2w+4}}{2} \int d\mu(l)d\mu(l')\delta^{(d)}(Q-l-l') =
$$

$$
\frac{\pi \Gamma(3/2)}{(4\pi)^{2+w}\Gamma(3/2 + w)} \left( \frac{s}{4} \right)^w \left( 1 - \frac{s}{4} \right)^{1+w}.
$$
This expression agrees with the absorptive part of $J(s)$ in $d$ dimensions, see Eqs. (A.2, A.3). Therefore, at $d = 4$, one has

$$\text{Im} V_1(s) = \frac{(2\pi)^4}{2} \int d\mu(l) d\mu(l') \delta^{(4)}(Q - l - l') \bar{J}(\bar{t}) , \quad (A.7)$$

where the measure in (A.7) is now the ordinary four–dimensional one, obtained from (A.6) by putting $w = 0$. For $\bar{J}$ we insert its explicit expression (A.4) at $d = 4$. It is convenient to work out the phase space integral (A.7) in the center–of–mass frame where

$$Q^\mu = (\sqrt{s}, \vec{0}) , \quad p_{1}^\mu = (\sqrt{s}/2, 0, 0, p) , \quad p = \sqrt{s/4 - 1} .$$

After integration over $l'$, one is left with an integral over the three–momentum $\vec{l}$. Using the remaining one–dimensional delta function, all integrals except the one over the angle $\theta(\vec{l}, \vec{p}_1)$ can be done easily. The integral left over is proportional to

$$\int_{-1}^{1} dz \left[ \sigma_1 \ln \frac{\sigma_1 - 1}{\sigma_1 + 1} + 2 \right] , \quad \sigma_1 = \sqrt{1 + \frac{2}{p(1 - z)}} .$$

After the change of variables $(\sigma_1 - 1)/(\sigma_1 + 1) = v$, we find

$$\text{Im} V_1(s) = \frac{1}{4(4\pi)^3} \left[ 3\sigma + \ln \frac{1 - \sigma}{1 + \sigma} - \frac{1}{s\sigma} \ln^2 \frac{1 - \sigma}{1 + \sigma} \right] , \quad \sigma = (1 - 4/s)^{1/2} . \quad (A.8)$$

It remains to construct a function with the proper cut structure and the correct behaviour at $s \to 0, \infty$. We find

$$\bar{V}_1(s) = \frac{1}{(16\pi^2)^2} \left[ (3 - \frac{\pi^2}{3s\sigma^2}) f + \frac{1}{2\sigma^2} f^2 - \frac{1}{3s\sigma^4} f^3 + 6 + \frac{\pi^2}{6} \right]$$

with

$$f = \sigma \ln \frac{1 - \sigma}{1 + \sigma} + i\pi \sigma .$$

In the notation of Ref. [10], this is

$$\bar{V}_1(s) = \frac{3}{N} J(s) + \frac{K_1(s)}{2} - \frac{K_3(s)}{3} .$$

Of course, exactly the same method can be applied to integrals with a more complicated numerator.

A.3 The sunset diagram

For the sunset diagram integrals of the type

$$(H; H^\mu; H^{\mu
u}) = \left\langle \left\langle \frac{(1; l_1^\mu, l_1^\nu)}{[1 - l_1^2][1 - l_2^2][1 - (p - l_1 - l_2)^2]} \right\rangle \right\rangle \quad (A.9)$$
have to be calculated. Here we again focus on the scalar integral $H$, the remaining ones can be done analogously. For $H$ we also present the procedure for the infinite part. Using the $d$-dimensional dispersion representation (A.2) for $J$, we get

$$H = \int_4^\infty [ds'] \int_0^1 dx \frac{1}{x + s'(1 - x) - p^2 x (1 - x) - l_1^2}.$$  

The $d^d l_1$ integrals can be performed easily and the result is

$$H(p^2) = \int_4^\infty [ds'] \int_0^1 dx F_2[z_2],$$  

where

$$F_2[z_2] = \frac{\Gamma(-\omega)}{(4\pi)^{2+\omega}} z_2^\omega,$$

$$z_2(p^2) = x + s'(1 - x) - p^2 x (1 - x).$$  

We subtract and add the two first terms of the Taylor series of $F_2[z_2]$ in $p^2$ around $p^2 = 1$ and obtain for the finite part at $d = 4$

$$H(p^2) - H(1) - (p^2 - 1)H'(1) = \int_4^\infty ds' \sqrt{1 - \frac{4}{s'}} \int_0^1 dx \mathcal{K}_2(s', x; p^2),$$

where we have introduced the kernel

$$\mathcal{K}_2(s', x; p^2) = \frac{1}{16\pi^2} \lim_{\omega \to 0} \left\{ F_2[z_2(p^2)] - F_2[z_2(1)] - (p^2 - 1)F'_2[z_2(1)] \right\}$$

$$= -\frac{1}{(16\pi)^2} \left\{ \ln \frac{z_2[p^2]}{z_2[1]} + \frac{(p^2 - 1)x(1 - x)}{z_2[1]} \right\}.$$  

The integral $\int dx \mathcal{K}_2$ could further be done in closed form – the result amounts to a twice subtracted one-loop self-energy integral with two propagators (with masses 1 and $s'$). In the text, we use

$$\overline{H}(p^2) = \frac{1}{(p^2 - 1)^2} \int_4^\infty ds' \sqrt{1 - \frac{4}{s'}} \int_0^1 dx \mathcal{K}_2(s', x; p^2),$$  

which is finite at $p^2 = 1$. We also need $H(1)$ and $H'(1)$, where the poles at $\omega = 0$ are contained. For the evaluation of the infinite parts a recursion relation can be set up by partial integration in $x$ in (A.10). This method gives

$$H(1) = -\frac{1}{(4\pi)^{4+2\omega}} \Gamma^2(-\omega) \left\{ \frac{3}{2} - \frac{17}{4} \omega + \frac{59}{8} \omega^2 + O(\omega^3) \right\},$$

$$H'(1) = -\frac{2}{(4\pi)^{4+2\omega}} \Gamma^2(-\omega) \left\{ \frac{1}{8} \omega + \frac{3}{16} \omega^2 + O(\omega^3) \right\}.$$  

In Ref. [49], the evaluation of the sunset integral is discussed in the general mass case.
B  Off-shell four-point function in $d$ dimensions

We display the four-point function to one loop in $d$ dimensions. More precisely, we use the sigma model parametrization (3.3) and define

$$i^3 \int dx_1\, dx_2\, dx_3\, e^{-i(p_1 x_1 + p_2 x_2 - p_3 x_3 - p_4 x_4)} \langle 0 | T \phi^i(x_1) \phi^k(x_2) \phi^l(x_3) \phi^m(x_4) | 0 \rangle$$

$$= \frac{Z^2}{\prod_i (M^2_i - p^2_i)} T^{\text{off-shell}}(s, t, u; p_1^2, p_2^2, p_3^2, p_4^2)$$

with

$$p_1 + p_2 = p_3 + p_4 ,$$

$$s = (p_1 + p_2)^2 , t = (p_1 - p_3)^2 , u = (p_1 - p_4)^2 .$$

The wave function renormalization constant $Z$ is the one appearing in the two-point function (1.2). In the standard isospin decomposition

$$T^{\text{off-shell}}(s, t, u; p_1^2, p_2^2, p_3^2, p_4^2) = \delta^{ik} \delta^{lm} A(s, t, u; p_1^2, p_2^2, p_3^2, p_4^2) + \text{cycl.} ,$$

the scattering amplitude is obtained by putting all momenta on the mass shell,

$$A(s, t, u) = A(s, t, u; M^2_\pi, M^2_\pi, M^2_\pi, M^2_\pi) = \frac{s - M^2}{F^2} + O(p^4) .$$

We find

$$F^4 A(s, t, u; p_1^2, p_2^2, p_3^2, p_4^2) =$$

$$(s - M^2) \left\{ F^2 + (2s + t + u - 3M^2) J_1(s) \right\}$$

$$+ \left\{ p_1^2 p_4^2 + p_2^2 p_3^2 - t(p_2^2 + p_3^2 - t) \right\} J_1(t)$$

$$+ \left\{ \Delta_{13} \Delta_{24} - t(\Delta_{13} - \Delta_{24} + t) \right\} J_2(t)$$

$$- 2t \left[ p_1^2 + p_4^2 - u \right] J_3(t) + (p_3, p_4, t) \rightarrow (p_4, p_3, u) \right\}$$

$$+ 8l_1 p_1 p_2 \cdot p_3 p_4 + 4l_2 \left[ p_1 p_3 \cdot p_2 p_4 + p_1 p_4 \cdot p_2 p_3 \right]$$

$$+ \left[ s + p_2^2 - p_1^2 - 5M^2/2 \right] T_M ,$$

where

$$J_1(s) = \frac{1}{2} J(s) , J_2(s) = -\frac{1}{s(d-1)} \left[ \left( M^2 - \frac{d}{4} s \right) J(s) + \left( \frac{d}{2} - 1 \right) T_M \right] ,$$

$$J_3(s) = \frac{1}{s(d-1)} \left[ \left( M^2 - \frac{s}{4} \right) J(s) - \frac{1}{2} T_M \right]$$

and $\Delta_{ik} = p_i^2 - p_k^2$.

(B.1)

(B.2)

Remarks:

In Sect. 4, we express the Mandelstam variables in units of the physical pion mass squared. For simplicity of notation, we use in this appendix the standard definition.
i) For on–shell momenta, the result agrees at \( d = 4 \) with the result given in [4].

ii) For off–shell pions, the amplitude is not finite at \( d = 4 \), in contrast to the off–shell amplitude considered in [4], where the four–point function of pseudoscalar densities was considered. In that case, there are additional contributions proportional to the low–energy constants \( l_3 \) and \( l_4 \) that remove the remaining divergences.

iii) It is not surprising that the above amplitude is not finite off–shell: The construction given in Ref. [4] only guarantees that the Green functions built from quark currents are ultraviolet finite – Green functions of pion fields are unphysical objects, even if they occur at intermediate steps of a calculation, as in the present context.

iv) Finally, we mention that these divergences in the off–shell amplitude do not generate nonlocal singularities in the two–loop calculation.

C Scattering lengths and effective ranges

From the explicit expression for the scattering amplitude in equation (4.15), it is straightforward to evaluate the threshold parameters \( a_l^I \) and \( b_l^I \). Using the definition (5.15), we find

\[
\begin{align*}
a_0^0 &= \frac{7M^2}{32\pi F^2_\pi} \left\{ 1 + \frac{x}{7} \left[ 49 + 5 \bar{b}_1 + 12 \bar{b}_2 + 48 \bar{b}_3 + 32 \bar{b}_4 \right] \\
&\quad + x^2 \left[ \frac{7045}{63} - \frac{215\pi^2}{126} + 10 \bar{b}_1 + 24 \bar{b}_2 + 96 \bar{b}_3 + 64 \bar{b}_4 + \frac{192}{7} \bar{b}_5 \right] \right\}, \\

b_0^0 &= \frac{1}{4\pi F^2_\pi} \left\{ 1 + \frac{x}{4} \left[ \frac{281}{9} + 4 \bar{b}_2 + 48(\bar{b}_3 + \bar{b}_4) \right] \\
&\quad + \frac{x^2}{4} \left[ \frac{77489}{81} - \frac{4135\pi^2}{72} + \frac{10}{3} \bar{b}_1 + \frac{592}{9} \bar{b}_2 + \frac{6448}{9} \bar{b}_3 + 688 \bar{b}_4 + 288 \bar{b}_5 - 32 \bar{b}_6 \right] \right\}, \\
a_0^2 &= -\frac{M^2}{16\pi F^2_\pi} \left\{ 1 - x \left[ 2 + \bar{b}_1 + 16 \bar{b}_4 \right] + x^2 \left[ \frac{262}{9} - \frac{22\pi^2}{9} + 4 \bar{b}_1 + 64 \bar{b}_4 \right] \right\}, \\

b_0^2 &= -\frac{1}{8\pi F^2_\pi} \left\{ 1 - \frac{x}{2} \left[ \frac{97}{18} - 2 \bar{b}_2 + 48 \bar{b}_4 \right] \\
&\quad + \frac{x^2}{2} \left[ \frac{10591}{81} - \frac{145\pi^2}{12} + \frac{11}{3} \bar{b}_1 - \frac{64}{9} \bar{b}_2 + \frac{32}{9} \bar{b}_3 + \frac{752}{3} \bar{b}_4 + 32 \bar{b}_6 \right] \right\},
\end{align*}
\]
\[a_1 = \frac{1}{24\pi F_\pi^2} \left\{ 1 + x \left[ -\frac{17}{36} + \bar{b}_2 + 8\bar{b}_4 \right] \right. \]
\[+ x^2 \left[ \frac{181}{162} + \frac{7\pi^2}{24} - \frac{5}{6}\bar{b}_1 - \frac{16}{9}\bar{b}_2 - \frac{16}{3}\bar{b}_3 - \frac{8}{3}\bar{b}_4 + 16\bar{b}_6 \right] \right\}, \]
\[b_1^i = \frac{1}{256\pi^3 F_\pi^4} \left\{ \frac{37}{135} - \frac{8}{3}\bar{b}_3 + 8\bar{b}_4 + \right. \]
\[+ x \left[ \frac{56981}{2430} - \frac{337\pi^2}{810} - 2\bar{b}_1 - \frac{196}{135}\bar{b}_2 - \frac{1888}{135}\bar{b}_3 - \frac{544}{135}\bar{b}_4 + \frac{64}{3}\bar{b}_6 \right] \right\}, \]
\[a_0^i = \frac{1}{480\pi^3 F_\pi^4} \left\{ -\frac{47}{72} + \bar{b}_3 + 7\bar{b}_4 + \right. \]
\[+ x \left[ \frac{7003}{2160} + \frac{169\pi^2}{2160} + \frac{1}{12}\bar{b}_1 - \frac{11}{9}\bar{b}_2 - \frac{152}{45}\bar{b}_3 - \frac{364}{45}\bar{b}_4 + 32\bar{b}_6 \right] \right\}, \]
\[a_2^i = \frac{1}{480\pi^3 F_\pi^4} \left\{ -\frac{49}{360} + \bar{b}_3 + \bar{b}_4 + \right. \]
\[+ x \left[ -\frac{67}{2160} - \frac{127\pi^2}{432} + \frac{29}{60}\bar{b}_1 + \frac{19}{90}\bar{b}_2 + \frac{28}{45}\bar{b}_3 + \frac{188}{45}\bar{b}_4 + 8\bar{b}_6 \right] \right\}, \]
\[(C.1)\]

where
\[x = \frac{M^2}{16\pi^2 F_\pi^2}, \quad \bar{b}_{1,2,3,4} = 16\pi^2 b_{1,2,3,4} \quad \text{and} \quad \bar{b}_{5,6} = (16\pi^2)^2 b_{5,6}. \]
\[(C.2)\]

The coefficients \(b_i\) are displayed in appendix D. The terms between the last square brackets in the expressions for \(a_I^l\) and \(b_I^l\) generate contributions of \(O(p^8)\) – these are beyond the accuracy we aim at here. In order to keep the formulae as simple as possible, we nevertheless retain them. In our numerical results these are removed.

D  The constants \(b_i\)

The quantities \(b_i\) in Eqs. (4.14) and (4.15) stand for
\[b_1 = 8 l'_1 + 2 l'_3 - 2 l'_4 + \frac{7}{6}L + \frac{1}{16\pi^2} \frac{13}{18} \]
\[+ x_2 \left\{ \frac{1}{16\pi^2} \left[ \frac{56}{9} l'_1 + \frac{80}{9} l'_2 + 15 l'_3 + \frac{26}{9} l'_4 + \frac{47}{108}L - \frac{17}{216} - \frac{1}{16\pi^2} \frac{3509}{1296} \right] \right\} \]

48
\[ + \frac{1}{6} [4k_1 + 28k_2 - 6k_3 + 13k_4] + [32l_1^r + 12l_3^r - 5l_4^r] l_4^r - 8l_3^{r2} + r_1^r \] ,

\[ b_2 = -8l_1^r + 2l_4^r - \frac{2}{3} L - \frac{1}{16\pi^2} \left( \frac{1}{9} l_2^r - \frac{16}{9} l_3^r - 8 l_4^r - \frac{203}{54} L + \frac{317}{3456} - \frac{1}{16\pi^2} \cdot \frac{1789}{432} \right) \]

\[ b_3 = 2l_1^r + \frac{1}{2} l_2^r - \frac{2}{3} L - \frac{1}{16\pi^2} \left( \frac{1}{2} l_4^r - \frac{7}{12} L \right) + x_2 \left( \frac{1}{16\pi^2} \left( \frac{178}{9} l_1^r + \frac{38}{3} l_2^r - \frac{7}{3} l_4^r - \frac{365}{216} L \right) \right) \]

\[ b_4 = \frac{1}{2} l_2^r - \frac{1}{6} L - \frac{1}{16\pi^2} \left( \frac{1}{9} l_4^r - \frac{4}{9} l_4^r - \frac{5}{9} l_4^r + \frac{47}{216} L \right) \]

\[ b_5 = \frac{1}{16\pi^2} \left( -\frac{31}{6} l_1^r - \frac{145}{36} l_2^r + \frac{625}{288} L + \frac{7}{864} - \frac{1}{16\pi^2} \frac{64029}{20736} - \frac{21}{16} k_1 - \frac{107}{96} k_2 + r_5^r \right) \]

\[ b_6 = \frac{1}{16\pi^2} \left( -\frac{7}{18} l_1^r - \frac{35}{36} l_2^r + \frac{257}{864} L + \frac{1}{432} - \frac{1}{16\pi^2} \frac{11375}{20736} - \frac{5}{48} k_1 - \frac{25}{96} k_2 + r_6^r \right) \]

where

\[ L = \frac{1}{16\pi^2} \ln \frac{M_\pi^2}{\mu^2} \]

\[ k_i = (4l_i^r(\mu) - \gamma_i L) L ; \quad \gamma_1 = \frac{1}{3} , \quad \gamma_2 = \frac{2}{3} , \quad \gamma_3 = -\frac{1}{2} , \quad \gamma_4 = 2 . \]

We have denoted by \( l_i^r \) (\( r_i^r \)) the renormalized, quark mass independent couplings from \( \mathcal{L}_4 (\mathcal{L}_6) \), with \( \mu \frac{dl_i^r}{d\mu} = -\frac{\gamma_i}{16\pi^2} \). In the text, we also use the parameters \( \bar{l}_i \), defined by

\[ l_i^r = \frac{\gamma_i}{32\pi^2} \left( \bar{l}_i + \ln \frac{M_\pi^2}{\mu^2} \right) . \]

The scale dependence of \( r_i^r \) is fixed by the requirement \( \mu \frac{db_i}{d\mu} = 0 \).
