Abstract

Most machine learning systems for natural language processing are tailored to specific tasks. As a result, comparability of models across tasks is missing and their applicability to new tasks is limited. This affects end users without machine learning experience as well as model developers. To address these limitations, we present DERE, a novel framework for declarative specification and compilation of template-based information extraction. It uses a generic specification language for the task and for data annotations in terms of spans and frames. This formalism enables the representation of a large variety of natural language processing challenges. The backend can be instantiated by different models, following different paradigms. The clear separation of frame specification and model backend will ease the implementation of new models and the evaluation of different models across different tasks. Furthermore, it simplifies transfer learning, joint learning across tasks and/or domains as well as the assessment of model generalizability. DERE is available as open-source software.

1 Introduction

A large number of tasks in natural language processing (NLP) are information extraction (IE) tasks, such as n-ary relation extraction (Doddington et al., 2004; Mintz et al., 2009; Hendrickx et al., 2010), semantic role labeling (Das et al., 2014) and event extraction (Kim et al., 2009; Doddington et al., 2004). Researchers address these tasks with a variety of different model paradigms, such as support vector machines (Rink and Harabagiu, 2010), convolutional neural networks (Collobert et al., 2011; Zeng et al., 2014) and recurrent neural networks (Tang et al., 2015; Nguyen et al., 2016).

This landscape of different tasks and models gives rise to four challenges: (C1) Lack of generalizability: Most models are tailored to a specific task or setup, making it hard to transfer lessons learned between tasks; (C2) Lack of comparability: Although benchmark datasets are available for most tasks, end-to-end evaluation typically includes peripheral aspects, such as preprocessing components – thus, it is unclear to what extent reported improvements mark actual advances in the core models or model components; (C3) Difficulty of reusability: Given task-specific models inside complex systems, it is hard to reuse specific code or models; (C4) Difficulty of usage: Users typically have limited areas of expertise, but IE systems span a range of such areas. Thus, developers of IE tools may have trouble properly (re)training complex machine learning models, and end users without ML or CS background might even be unable to use existing tools.

To tackle these challenges, we develop the general framework DERE (Declarative Relation Extraction). It enables users to (i) specify (novel or established) IE tasks, (ii) compile models and transfer them across tasks without additional development effort, (iii) develop and evaluate models across tasks, (iv) formulate and address research questions, such as the investigation of model generalizability across tasks, transfer learning, or joint learning across tasks and/or domains, and (v) verify the generalizability of models by applying them to a large variety of tasks.

DERE achieves this by providing (a) a general mechanism to declaratively specify IE tasks and (b) a shared processing framework that decouples frontend and backend. This provides an attractive shared basis for modeling tasks which are typically perceived as being very different. In this paper, we use BioNLP event extraction and aspect-based sentiment analysis (ABSA) as examples. At the same time, the decoupling exposes accessible interfaces for different user groups (cf. Section 3).

*All authors contributed equally.
The declarative specification of a task (which we call a schema) builds upon spans and relations between spans as basic concepts which are used by essentially all IE tasks. To model n-ary relations, we propose a slot-filling scheme in which frames model n-ary relations and their arguments. Figure 1 shows the general structure of frames (below) and two concrete instantiations for ABSA and BioNLP (above). Each frame is triggered (anchored) by a span, e.g., a subjective evaluating phrase like “very stylish” or a BioNLP event trigger, such as “regulation” or “involves”.

Frames hold a task-specific number of typed slots, filled by relation arguments. The frames for ABSA have a slot filled by the target (aspect) of the sentiment while the frames for the BioNLP regulation event hold a Theme slot and an optional Cause slot. While triggers are always textual spans, slots can be filled by either spans or frames, depending on the task specification. We argue that this simple setup can model most IE tasks. Note that the framework poses no theoretical restrictions to the window from which frames are extracted. Thus, it can model sentence-level, document-level as well as multi-document tasks.

2 Related Work

Several applications require the joint extraction of spans and relations between spans, such as the BioNLP shared task (Kim et al., 2009), semantic role labeling (Das et al., 2014) or (temporal) slot filling (Surdeanu, 2013). However, all systems we are aware of for solving these tasks are tailored to specific scenarios (Angeli et al., 2016; Adel et al., 2016, i.a.). As a result, it is not straightforward to apply them to other use cases. In contrast, our framework is designed to be task- and domain-independent.

Clarke et al. (2012) develop an NLP component manager which combines several existing NLP tools in a pipeline. Similarly, Curran (2003) aims at a general NLP infrastructure but only reports implementations of non-relational sequence-tagging tasks. Examples of the few available toolkits which are intended to provide users with the possibility of automatically extracting information from text data are Jet (Java Extraction Toolkit), GATE (General Architecture for Text Engineering, Cunningham et al., 2013), UIMA (Unstructured Information Management Architecture, Ferrucci and Lally, 2004), FACTORIE (McCallum et al., 2009) and Stanbol which integrates other NLP frameworks, e.g., OpenNLP (Morton et al., 2005).

Stanbol and OpenNLP, however, focus on tagging tasks and do not provide tools for relation extraction. FACTORIE is a general approach to formulate factor graphs for arbitrary tasks. Our framework takes arbitrary model paradigms as a backend and is focused on IE, which enables the abstraction layers introduced earlier. Jet, on the other hand, is an IE engine developed specifically for the ACE task specification.

GATE is most similar to our framework in scope. It offers both a framework for programmers and an environment for language engineers and computational linguists. However, it is a very general framework and working with it requires both domain and machine learning knowledge. In contrast, our framework provides end users with an interface for training models on new tasks without requiring any specific knowledge.

3 Framework Design

Use Cases. We address the needs of the following three user groups with associated use cases:

(1) Researchers/Model developers: Our framework helps researchers to formulate their models in a task-independent manner, such that they can be tested and compared across tasks. This addresses challenges C1, C2 and C3 mentioned in Section 1.

(2) Developers of IE tools for a new use case: Our framework provides a common interface to models previously developed for other tasks. Those mod-
null
implementation. Note that this is only a proof-of-concept baseline but the framework is not limited to pipeline models. In the future, we will develop joint models that can cope with recursive structures.

**Span Identification.** We cast the span identification problem as a BIO-style sequence-labeling task that predicts the span boundaries. To model overlapping spans, we train one model per span type which outputs all spans of that type. Our proof-of-concept system uses conditional random fields (CRF, Lafferty et al., 2001). The feature set consists of the lower-cased words, their stems, their shape (orthographic case, digits, punctuation), and a flag indicating whether the word is included in a task-specific gazetteer. All features (except the last one) are applicable to any NLP task. The gazetteer feature is based on a simple lexicon of label-specific words (e.g., positive words for detecting positive spans for sentiment analysis) and can be instantiated without any technical knowledge.

**Slot Classification.** Once the spans are identified, the slot classifier is used to predict which slots of which frame they are likely to fill. We break this question down to a classification task at the level of span pairs – one anchor span representing a frame, and another span representing a potential argument. The search space is restricted to those pairs with compatible types according to the schema.

Formally, the classifier takes as input the set $S$ of all spans identified previously, along with a task schema. For each pair $(s_i, s_j) \in S^2$ of spans following the task schema, our classifier produces as output either a single relation label $r_{ij}$, or NR (no relation)$^3$ if the two spans are unrelated. Conceptually, two spans $s_i$ and $s_j$ are related iff $s_i$ anchors a frame, and $s_j$ fills a slot in that same frame. Relation labels $r_{ij}$ are pairs $(f_i, l_j) \in T_F \times L$, where $f_i$ is the frame type anchored by $s_i$ and $l_j$ is the slot type in $f_i$ that $s_j$ fills. This enables us to model, e.g., in the task schema in Figure 3, BINDING THEME and GENE_EXPRESSION THEME as separate relations. A linear support vector machine is used to predict the most likely relation label (or NR). Users can enable subsampling of negative examples.

As outlined in the introduction, the features we take into account are included with the aim of being task-agnostic. Intra-span features are types of identified spans and the bag of words in both spans. Inter-span features take into account context. We use the bag of words of tokens between the spans, and of the tokens on the shortest path connecting the spans in a parsed dependency tree, which we assume to accurately capture the relationship expressed by the slot that links the two spans. Since spans can contain multiple tokens, there can be several shortest paths between tokens from the two spans. Under the assumption that tokens in a span are closely related to each other, we select the shortest of these paths. In addition, we also use a bag of bigrams of alternating label-token sequence on that same path. Finally, we measure the length of the shortest path and the token distance.

**Decoding.** Once the slot classifier identifies all related span pairs, the decoding step generates frames. Pairs of spans $(s_i, s_j)$ that stand in a relation $r$ are first partitioned into equivalence classes $C_h$ according to their anchor span (i.e., $(s_i, s_j) \in C_i$). It would be possible to produce one frame for each equivalence class $C_h$, anchored by the common anchoring span $s_h$, and with slots filled according to each span pair’s relation label $r$. However, as equivalence classes can be arbitrarily large, this would allow for each slot to be filled by arbitrarily many spans (as illustrated in the bottom-left of Figure 5). As the task schema might impose cardinality constraints, further processing is required to ensure that all produced frames are consistent with the task schema. For each equivalence class $C_h$, we consider all possible legal frames – i.e., all frames that are consistent with the task schema and whose slots are filled according to some subset of $C_h$. Of these legal frames, we retain all maximally-filled legal frames (see bottom-right of Figure 5).

**Evaluation and Results.** To prove the feasibility of our proof of concept, we report results with this configuration on the 2009 BioNLP shared task, for which we re-use the original evaluation machin-

| Event Class         | Precision | Recall | F1  |
|---------------------|-----------|--------|-----|
| Gene expression     | 68.12     | 57.30  | 62.25 |
| Transcription       | 70.59     | 14.63  | 24.24 |
| Protein catabolism  | 64.00     | 76.19  | 69.57 |
| Phosphorylation     | 65.85     | 57.45  | 61.36 |
| Localization        | 78.57     | 41.51  | 54.32 |
| SVT TOTAL           | 68.46     | 50.27  | 57.97 |

Table 1: Performance of the proof-of-concept system for biomedical relation extraction (BioNLP ’09 dev set)

| Sentiment Class     | Precision | Recall | F1  |
|---------------------|-----------|--------|-----|
| Positive            | 41.07     | 24.19  | 28.57 |
| Negative            | 26.68     | 7.15   | 11.00 |
| Neutral             | 5.83      | 4.50   | 5.08  |

Table 2: Performance of the proof-of-concept system for aspect based sentiment analysis (10-fold cross-validation on USAGE corpus).

The choice of Python will also help with future integration of neural network models. For the proof-of-concept backend, we use scikit-learn for feature extraction and training (Pedregosa et al., 2011) with crfsuite and liblinear. Tokenization and stemming is done with NLTK (Loper and Bird, 2002), dependency features are extracted with spacy (Honnibal and Johnson, 2015) and dependency graphs are stored and processed using NetworkX (Schult, 2008). The code is available under the Apache 2.0 License.\(^2\)

5 Conclusion and Future Work

This paper presented DeRE, a general framework for declarative specification and compilation of template-based slot filling. It addresses the needs of three groups of users: backend model developers, developers of information extraction tools for new use cases and end users of information extraction tools. Especially, it simplifies the evaluation and comparison of new information extraction models across tasks as well as the straightforward application of existing models to new tasks. By our general design of spans and frames, it is possible to apply DeRE to a large variety of natural language processing tasks, such as unary, binary and n-ary relation extraction, event extraction, semantic role labeling, aspect-based sentiment analysis, etc.

As BRAT annotations are not as expressive as our task schema files, we plan to extend the frontend of DeRE by supporting a native, XML-based annotation format in the future. For the backend, our goal is to develop a variety of state-of-the-art models with joint span identification, slot classification, and frame decoding, e.g., neural networks with structured-prediction output layers (Lample et al., 2016; Adel and Schütze, 2017, i.a.). Given a variety of different models and tasks, we will be able to address interesting research questions, such as transfer learning and joint learning across tasks and domains. We plan to further analyze the usage of DeRE and the possibilities it provides for integrating different model types and configurations in a multi-task oriented shared task.
