CYCLE CLASSES ON THE MODULI OF K3 SURFACES IN POSITIVE CHARACTERISTIC

TORSTEN EKEDAHLL AND GERARD VAN DER GEER

Abstract. This paper provides explicit closed formulas in terms of tautological classes for the cycle classes of the height and Artin invariant strata in families of K3 surfaces. The proof is uniform for all strata and uses a flag space as the computations in [EG10] for the Ekedahl-Oort strata for families of abelian varieties, but employs a Pieri formula to determine the push down to the base space.

1 Introduction

Moduli spaces of algebraic varieties in positive characteristic possess stratifications for which there are no analogues in characteristic zero. Besides the moduli of abelian varieties, where this phenomenon has attracted a lot of attention, the moduli of K3 surfaces provide a beautiful example. The middle de Rham cohomology of a K3 surface in positive characteristic carries two filtrations, the Hodge filtration and the conjugate filtration. The relative position of these two filtrations yields an invariant of the K3 surface and leads to a stratification of the moduli of polarized K3 surfaces. The strata are indexed by the height of the formal Brauer group of the K3 surface and by the Artin invariant if the K3 surface is supersingular (in Artin’s sense).

It is the purpose of this paper to calculate closed formulas for the cycle classes of these strata. For the strata indexed by the height of the formal Brauer group this was done in [GK00] in a somewhat ad hoc manner, but for the more elusive strata parametrized by the Artin invariant this problem remained open. We consider here the moduli of K3 surfaces together with an embedding of a non-degenerate lattice in the Néron-Severi group. In the case of abelian varieties it was shown [EG10] that for computing the classes the algebraic group $Sp(2g)$ played an essential rôle. By analogy with the complex one would perhaps expect that in the case of K3-surfaces the special orthogonal group $SO(n)$ would play a similar rôle. This is almost but not quite the case, it turns out that it is rather the full orthogonal group $O(n)$ that governs the situation. When the dimension $n$ (of the primitive part of cohomology) is odd the distinction between $SO(n)$ and $O(n)$ is not really seen (essentially as $O(n)$ acts trivially on the Dynkin diagram). The case of an even $n$ is markedly different (as this time $O(n)$ acts non-trivially on the Dynkin diagram). If we consider the relevant homogeneous space, the space of isotropic 1-dimensional subspaces in the orthogonal $n$-dimensional vector space, the poset of Schubert varieties is not a total order; there are two mid-dimensional incomparable Schubert varieties (which are permuted under $O(n)$). On the other hand the strata given by height and Artin invariant seems to form a linearly ordered stratification. The solution to this conundrum is that there is a deformation invariant, the Hodge discriminant which, depending on its value, excludes one of the mid-dimensional strata and leaves us with a linearly ordered set of strata.

Apart from these complications that appear when $n$ is even, our strategy for finding cycle class formulas is the same whether $n$ is even or odd. Just as for the abelian case (cf., [loc. cit.]) we work with a space of complete flags extending the Hodge filtration and first obtain formulas there for the classes of strata that are in bijection with the Schubert cells on the complete flag space (of $SO(n)$). We then push down these formulas to the moduli space under consideration. At this point however we follow a strategy which is different from that used in [loc. cit.]: Instead of using formulas of Fulton and Pragacz we shall use a Pieri type formula. This introduces a new problem. This Pieri formula involves many different strata all of which will have to be pushed down to the moduli space. Comparing with the map from the complete flag space $F\ell(n)$

2000 Mathematics Subject Classification. 14C17,14J28,14H10
Theorem A

The cycle classes of the final strata \( \overline{\nu}_w \) on the moduli space are polynomials in \( \lambda_1 \) with coefficients that are 1/2 times an integral polynomial in \( p \neq 2 \) given by

\[
\begin{align*}
\text{i)} \quad [\overline{\nu}_w] &= (p-1)(p^2-1) \cdots (p^{k-1}-1)\lambda_1^{k-1} \quad \text{if } 1 \leq k \leq m, \\
\text{ii)} \quad [\overline{\nu}_{w_{m+1}}] &= \frac{1}{2}(p-1)(p^2-1) \cdots (p^m-1)\lambda_1^m, \\
\text{iii)} \quad [\overline{\nu}_{w_{m+k}}] &= \frac{1}{2} \left( \frac{p^{2k-1}(p^{2(k+1)-1}) \cdots (p^{2m-1})}{(p+1) \cdots (p^{m-k+1}+1)} \right) \lambda_1^{m+k-1} \quad \text{if } 2 \leq k \leq m.
\end{align*}
\]

Remark: The factor 1/2 seems to be related to the fact that the formulas of [3K01] counts the infinite height stratum doubly (cf. [3K01]).

The formulas for the height strata were already determined in [3K01]. The above theorem corresponds to the case where \( n = 2m + 1 \) is odd. The more general case of moduli stacks of K3 surfaces with a marking of a non-degenerate lattice in their Néron-Severi group forces us to treat also the subtler case where \( n \) is even. We finish this paper by giving two examples that show that the even case appears quite naturally.

When dealing with K3-surfaces we do not have to go further than \( n = 21 \). However, our results should also be applicable to other moduli spaces related to arithmetic subgroups of the orthogonal group, like moduli spaces of hyperkähler manifolds in positive characteristic which would give examples with larger \( n \).

Conventions: Throughout this paper we assume that the characteristic \( p \) is not 2 as orthogonal groups show a different behavior in characteristic 2.

2 Combinatorics

We start with an auxiliary section on the combinatorics of the Weyl groups associated to our orthogonal groups. We distinguish the B, C and D cases.
2.1 B and C combinatorics

The Weyl group $W^B_m$ of $SO(2m+1)$ can be identified with the subgroup of $S_{2m+1}$, the symmetric group on $2m+1$ letters, consisting of the permutations $\sigma \in S_{2m+1}$, for which $\sigma(i) + \sigma(2m+2-i) = 2m+2$. We shall specify such a permutation by giving the images of the $1 \leq i \leq m$ as $[a_1, a_2, \ldots, a_m]$. Thus the conditions that this specify an element of $W^B_m$ is that $a_i \notin \{a_1, m+1, 2m+2-a_j\}$ for all $i \neq j$. The elements which are reduced with respect to the set of roots obtained by removing the first root (so that the remaining roots form a root system of type $B_{m-1}$) are precisely those of the form $[a_1, a_2, \ldots, a_m]$ with $a_1 \neq m+1$ and $a_2, \ldots, a_m$ being an increasing sequence consisting of the first $m-1$ integers $\geq 1$ which are different from $a_1$ and $2m+2-a_1$ (cf., [BL00, §3.4]). We write them as $w_m \in [2m+2-a_1, 1, 2, 3, \ldots]$ including of course examples such as $[2, 1, 3, \ldots]$ and $[2m+1, 2, 3, \ldots]$. We shall call these elements the final elements of $W^B_m$. There are $2m$ final elements. We have $w_{2m} = 1$ and we sometimes write $w_0$ for $w_1$.

The simple reflections $s_i$ for $i = 1, \ldots, m$ of $W^B_m$ are the permutations $s_i = (i, i+1)(2m+1-i, 2m+2-i)$ for $i = 1, \ldots, m-1$ and $s_m = (m, m+2)$. We also define the weight representation of $W^B_m$ on $\mathbb{Z}^m$ with basis vectors $e_i$ $(i = 1, \ldots, m)$ given by, for $\sigma \in W^B_m$,

$$\sigma(e_i) = \begin{cases} e_{\sigma(i)} & \text{if } \sigma(i) \leq m \\ -e_{2m+2-\sigma(i)} & \text{if } \sigma(i) > m. \end{cases}$$

We thus can view $W^B_m$ as a reflection group of this lattice. In particular, for an element $\alpha \in \mathbb{Z}^m$ we have the reflection $s_\alpha$ in $\alpha$ with $s_\alpha(x) = x - \langle \alpha, x \rangle \alpha$; e.g. $s_i = s_{e_i}$.

For a permutation $w$ of $\{1, 2, \ldots, n\}$ we define

$$r_w(i, j) = \#\{1 \leq a \leq i : w(a) \leq j\}$$

for $1 \leq i, j \leq n$. It is clear that a permutation is determined by this function. The length of an element of $W^B_m$ (in the sense of Coxeter groups) may be described in concrete terms as

$$\ell(w) = \#\{1 \leq i \leq j \leq m \mid w(i) > w(j)\} + \#\{1 \leq i \leq j \leq m \mid w(i) + w(j) > 2m+2\}.$$ 

We shall occasionally have to deal with the Weyl group $W^C_m$ of $Sp(2m)$. It has almost exactly the same description as $W^B_m$ except that it is seen as subgroup of $S_{2m}$:

$$W^C_m := \{\sigma \in S_{2m} | \sigma(i) + \sigma(2m+1-i) = 2m+1\};$$

a correspondence between them is given by $w \in W^B_m$ defining an element $w' \in W^C_m$ by $w' := \sigma w \sigma^{-1}$ where $\sigma(i) = i$ if $1 \leq i \leq m$ and $\sigma(i) = i-1$ if $m+1 < i \leq 2m+1$. The length of an element is given by

$$\ell(w) = \#\{1 \leq i < j \leq m \mid w(i) > w(j)\} + \#\{1 \leq i \leq j \leq m \mid w(i) + w(j) > 2m+1\}.$$ 

Finally, we define the discriminant, $\text{disc}(w) \in \{+1, -1\}$, of $w \in W^B_m$ to be the signature of $w$ as an element of $S_{2m+1}$. The reason for calling this homomorphism disc will appear later.

2.2 D combinatorics

The Weyl group $W^D_m$ of $SO(2m)$ consists of the permutations in $\sigma \in S_{2m}$ for which $\sigma(i) + \sigma(2m+1-i) = 2m+1$ and such that there is an even number of $1 \leq i \leq m$ for which $\sigma(i) > m$. The subgroup of $S_{2m}$ fulfilling the same conditions except for the parity condition form a subgroup of $S_{2m}$ which can be identified with the Weyl group $W^D_m$ for $Sp(2m)$. Hence $W^D_m$ is a subgroup of $W^C_m$ of index 2 and more precisely it is the kernel of the signature homomorphism $\text{disc}: W^C_m \to \{+1, -1\}$. We specify a permutation of $W^C_m$ as $[a_1, a_2, \ldots, a_m]$. Thus the conditions that
this specify an element of \( W_C^m \) is that \( a_i \notin \{a_j, 2n + 1 - a_j \} \) for all \( i \neq j \) and it belongs to \( W_D^m \) if also the number of \( a_i \) with \( a_i + m > 1 \) is even. The length of an element fulfills the formula

\[
\ell(w) = \# \{ 1 \leq i < j \leq m \mid w(i) > w(j) \} + \# \{ 1 \leq i < j \leq m \mid w(i) + w(j) > 2m + 1 \}.
\]

The simple reflections \( s_i, i = 1, \ldots, m, \) of \( W_D^m \) are the permutations \( s_i = (i, i + 1)(2m - i, 2m + 1 - i) \) for \( i = 1, \ldots, m - 1 \) and \( s_m = (m - 1, m + 1)(m, m + 2) \). The simple reflections of \( W_C^m \) are the \( s_i, i = 1, \ldots, m - 1 \), and \( s_m' = (m, m + 1) \). We also have the weight representation of \( W_C^m \) on \( \mathbb{Z}^m \) with basis vectors \( e_i \) (\( i = 1, \ldots, m \)) given by

\[
\sigma(e_i) = \begin{cases} 
\epsilon_{\sigma(i)} & \text{if } \sigma(i) \leq m \\
-\epsilon_{2m+1-\sigma(i)} & \text{if } \sigma(i) > m.
\end{cases}
\]

Note that the fact that the larger group is equal to \( W_C^m \) is somewhat accidental. To us it will rather be the Weyl group of \( O(2m) \) (as opposed to the Weyl group of \( \text{SO}(2m) \)) or, equivalently, as the group generated by \( W_D^m \) and the non-trivial graph automorphism of \( D_m \) (which in the \( D_4 \) case is the one permuting the last two vertices). From the latter point of view \( s_m' \) gives a non-trivial graph automorphism, indeed it commutes with \( s_i, 1 \leq i < m - 1 \) and conjugation by it permutes \( s_{m-1} \) and \( s_m \). To emphasize this point of view we shall, when relevant, write the supergroup \( W_C^m \) as \( W_D^m \). In this context we need a definition of length on \( W_D^m \) that mimics the length of \( W_D^m \) (rather than on \( W_C^m \)) and which we shall therefore denote \( \ell_D \):

\[
\ell_D(w) = \# \{ 1 \leq i < j \leq m \mid w(i) > w(j) \} + \# \{ 1 \leq i < j \leq m \mid w(i) + w(j) > 2m + 1 \}
\]

It has the property that its restriction to \( W_D^m \) equals its natural length and that \( \ell_D(ws_m') = \ell_D(w) \).

The elements which are reduced with respect to the set of roots of \( D_m \) obtained by removing the first root (so that the remaining roots form a root system of type \( D_{m-1} \)) are precisely those of the form \([a_1, a_2, \ldots, a_m] \) with \((a_2, \ldots, a_m)\) being the lexicographically smallest sequence of integers making \([a_1, a_2, \ldots, a_m] \) an element of \( W_D^m \). We write them as \( w_a := [2m + 1 - a, 1, 2, 3, \ldots] \), including of course examples such as \([2, 1, 3, \ldots, m], [m + 1, 1, 2, \ldots, m - 1, m + 2], \) and \([2m, 2, 3, \ldots, m - 1, m + 1] \). We shall call these elements the final elements of \( W_D^m \). There are \( 2m \) final elements. The longest one is \( w_1 \) which we shall also denote \( w_0 \). It has the reduced expression \( s_1s_2 \cdots s_{m-2}s_{m-1}s_ms_{m-2} \cdots s_1 \). We also put \( w_a' := w_ks_m', \) and we shall call these the twisted final elements with the alternative notation \( w_0' \) for \( w'_1 \).

### 3 Flag spaces

We shall be interested in flags in a finite-dimensional orthogonal or symplectic space and we start by recalling some well-known facts. Let thus \( V \) be an \( n \)-dimensional vector space over a field \( k \) provided with a non-degenerate quadratic or symplectic form \( \langle - , - \rangle \). A flag \( (0) = V_0 \subset V_1 \subset V_2 \subset \ldots \subset V_r \) of subspaces of \( V \) is called isotropic if the restriction of the form to \( V_r \) is zero. We say that the flag is maximal if \( r = k := [n/2] \) (and hence \( \dim(V_i) = i \)). We can extend a maximal flag to a self-dual complete flag by putting \( V_j = V_{n-j}^\perp \).

The group \( \text{SO}(n) \) does not always acts transitively on complete flags. Indeed, given a flag \( V \), we get a canonical isomorphism \( \det(V) = \det(V_k) \otimes \det(V/V_k) \). The pairing induces an isomorphism \( V_k \cong (V/V_k)^\vee \) and hence a canonical isomorphism \( \det(V) = \det(V_k) \otimes \det(V_k)^\vee \). This gives us a canonical element \( \alpha_k \in \det(V) \). It satisfies \( \alpha^2_k = \alpha^{-1}_k \). Two flags \( V \) and \( V' \) are in the same orbit under conjugation by \( \text{SO}(n) \) precisely when \( \alpha_k = \alpha_k' \) or equivalently precisely when \( \dim(V_k \cap V'_k) \equiv k \mod 2 \).

Now, given a complete flag \( V \), we may construct another complete flag \( V' \) as follows: We let \( V'_j = V_i \) for \( i \neq k \) and then let \( V'_j \) be the unique maximal totally isotropic subspace containing \( V_{k-1} \) and being contained in \( V_{k+1} \) that is distinct from \( V_k \). As \( V_k \cap V'_k = V_{k-1} \) we see that \( V \) and \( V' \) are not conjugate under \( \text{SO}(n) \). We shall call \( V' \) the flip of \( V \).
When the space is symplectic or $n$ is odd complete flags correspond precisely to Borel subgroups of the symplectic or special orthogonal group; one associates to a flag its stabiliser. The orthogonal even case is different however. To us the main difference is the fact that $SO(n)$ does not act transitively on complete flags.

This leads us to introduce the notion of *self-dual almost complete flag* (when $n = 2k$) which is specified by an isotropic flag $(0) = V_0 \subset V_1 \subset V_2 \subset \ldots \subset V_{k-1}$ where $\dim V_i = i$ (and hence extended to a larger flag by putting $V_j = V_{n-j}$ for $k + 1 \leq j \leq n$). If we let $\mathcal{F}_n$ be the space of almost complete flags and $\mathcal{F}'_n$ the space of complete flags, then the forgetful map $\mathcal{F}'_n \rightarrow \mathcal{F}_n$ is an étale double cover whose associated involution map $\mathcal{F}'_n \rightarrow \mathcal{F}'_n$ is given by the flip. Furthermore, $SO(n)$ acts transitively on $\mathcal{F}_n$ with stabilisers the Borel group of it. On the other hand $O(n)$ acts transitively both on $\mathcal{F}_n$ and $\mathcal{F}'_n$. The stabilisers for the action on $\mathcal{F}_n$ are subgroups of $O(n)$ whose intersection with $SO(n)$ are Borel subgroups and which map surjectively onto $O(n)/SO(n)$ whereas the stabilisers on $\mathcal{F}'_n$ are the Borel subgroups of $SO(n)$.

More generally if we have an orthogonal vector bundle $E \rightarrow X$ of constant rank $n = 2k$, then we have the bundle of almost complete flags $\mathcal{F}(E) \rightarrow X$ and complete flags $\mathcal{F}'(E) \rightarrow X$ and an étale double cover $\mathcal{F}'(E) \rightarrow \mathcal{F}(E)$. This double cover is actually the pullback of a double cover of $X$: The quadratic form on $E$ induces a perfect quadratic form on $det \mathcal{E}$, i.e., an isomorphism $det \mathcal{E} \otimes det \mathcal{E} \rightarrow \mathcal{O}_X$. This isomorphism is multiplied by $(-1)^k$ and the result is used to define a double cover, the *discriminant double cover*, $\pi: Y \rightarrow X$ with $\pi_*\mathcal{O}_Y = \mathcal{O}_X \oplus det \mathcal{E}$ and multiplication given by the (twisted by $(-1)^k$) isomorphism $det \mathcal{E} \otimes det \mathcal{E} \rightarrow \mathcal{O}_X$. The relativization of the construction of $\mathcal{O}_Y$ above gives us a section $\alpha$ of $det \mathcal{E}$ over $\mathcal{F}'(E)$ for which (after the twisting) has square 1. Hence we get a morphism $\mathcal{F}'(E) \rightarrow Y$ which fits into a cartesian diagram

\[
\begin{array}{ccc}
\mathcal{F}'(E) & \rightarrow & Y \\
\downarrow & & \downarrow \\
\mathcal{F}(E) & \rightarrow & X.
\end{array}
\]

The special properties of the even orthogonal case is the reason for the relevance of the group $W^D_m$ as the following proposition shows. It gives representatives for the orbits of pairs of flags.

**Proposition 3.1**

i) Let $e_1, \ldots, e_{2m}$ be the standard basis of a symplectic space with $\langle e_i, e_j \rangle = \delta_{i,2m+1-j}$ for $j \geq i$. The orbits of the action of $Sp(2m)$ on pairs of totally isotropic complete flags in $2m$-dimensional space are in bijection with the elements of the Weyl group $W_m$. The element $w \in W^C_m$ corresponds to the orbit of $(\sum_{j \leq i} ke_j, \sum_{j \leq i} ke_{w^{-1}(j)})$.

ii) Let $e_1, \ldots, e_{2m+1}$ be the standard basis of an orthogonal space with $\langle e_i, e_j \rangle = \delta_{i,2m+2-j}$. The orbits of the action of $SO(2m + 1)$ on pairs of totally isotropic complete flags in $2m+1$-dimensional space are in bijection with the elements of the Weyl group $W^B_m$. The element $w \in W^B_m$ corresponds to the orbit of $(\sum_{j \leq i} ke_j, \sum_{j \leq i} ke_{w^{-1}(j)})$.

iii) Let $e_1, \ldots, e_{2m}$ be the standard basis of an orthogonal space with $\langle e_i, e_j \rangle = \delta_{i,2m+1-j}$. The orbits of the action of $SO(2m)$ on pairs of totally isotropic complete flags in $2m$-dimensional space are in bijection with the elements of the group $W^D_m$. An element $w \in W^D_m$ corresponds to the orbit of $(\sum_{j \leq i} ke_j, \sum_{j \leq i} ke_{w^{-1}(j)})$. If $(F_*, D_*)$ lies in the orbit corresponding to $w$, then $disc(w) = (-1)^d$, where $d = \dim (E_m \cap D_m)$. Flipping the first flag changes the type from $w$ to $w s'_m$ and flipping the second changes it from $w$ to $s'_m w$.

**Proof:** The first and second part is of course well known, the third part perhaps less so but in any case is just as easy to prove.

We shall say that a basis such as in the proposition is *adapted* to the two flags. We shall also say that two complete flags are in *relative position* $w$ for $w \in W^C_m$, $W^B_m$ or $W^D_m$ respectively if they belong to the orbit above associated to $w$. Note that in the $B$ and $C$ cases we are dealing with orbits of $G$ (which equals $SO(2m + 1)$, resp. $Sp(2m)$) on the product of flag spaces $G/B \times G/B$ and we are dealing with the well-known bijection between such orbits. In the even orthogonal case (and when $k = k$) flags are in bijection with $O(2m)/B$, where $B$ is a Borel group.
of $\text{SO}(2m)$ (the stabiliser of a fixed flag) where of course $\text{O}(2m)/B$ has two components. Orbits under $\text{O}(2m)$ of pairs of flags are then in bijection with $W_m^D$. We may however reduce ourselves at will to just the action of $\text{SO}(2m)$ on $\text{SO}(2m)/B$. Indeed, $V_\bullet$ and $U_\bullet$ are in relative position $w$ precisely when $V_\bullet$ and $U_\bullet'$ are in relative position $w_s'$ where $U_\bullet'$ is the flip of $U_\bullet$.

All this relativizes to the situation of a symplectic or orthogonal vector bundle of rank $r$ over a base $S$ (in which 2 is invertible). We can then construct the flag bundle $\mathcal{F}(V)$ of complete self-dual flags in $V$. In the even orthogonal this factors as above through the discriminant cover, $D_V$, the double cover of $S$ classifying sections $\alpha$ of $\det(V)$ of square $\alpha^2 = (-1)^m$. The involution induced by $\alpha \mapsto -\alpha$ of $D$ over $S$ extends to an involution of $\mathcal{F}(V)$ taking a flag to its flip. The same terminology will be used for partial flags that contain a middle dimensional member.

4 F-zips

Recall (cf., [MW04]) that an orthogonal or symplectic F-zip is a tuple $(M, C^\bullet, D_\bullet, \varphi_\bullet)$, where $M$ is an orthogonal or symplectic vector bundle over a base of positive characteristic, $0 = C^0 \subseteq C^{r-1} \subseteq \cdots \subseteq C^r = M$ and $0 = D_0 \subseteq D_1 \subseteq \cdots \subseteq D_r = M$ are self-dual (not necessarily complete) flags on $M$ and $\varphi_\bullet$ a collection of isomorphisms $\varphi_i : F^*(C^i/C^{i+1}) \to D_{i+1}/D_i$ compatible with the isomorphisms $C^{i+1}/C^i \hookrightarrow (C^{r-i}/C^{r-i-1})^*$ and $D_{i+1}/D_i \hookrightarrow (D_{r-i}/D_{r-i-1})^*$ induced by the pairing. If the rank of $D_i$ has the constant value $n_i$ we say that the F-zip is of type $n = (n_r, n_{r-1}, \ldots, n_0)$. A flagged F-zip is an F-zip together with a complete self-dual flag $0 = E_0 \subseteq E_1 \subseteq \cdots \subseteq E_n = M$ with $C^i = E_{n_i}$ where $n_i := \text{rk}(C^i)$ (and $\text{rk}(E_i) = i$). We can use $\varphi_\bullet$ to extend the $D$ flag to a complete self-dual flag $G_\bullet$ by the condition that $D_{i+1} \subseteq G_{j'} \subseteq D_i$ when $C^i \subseteq E_j \subseteq C^{i+1}$, where $j' = j + n_{r-i-1} - n_i$, $m$ being the rank of $M$, and $G_{j'/D_{i+1}} = \varphi_i(F^*(E_j/C^i))$.

We now want to construct the stack of flagged F-zips. Starting from the algebraic stacks $\text{BO}(m)$ and $\text{BSp}(m)$ of orthogonal resp. symplectic vector bundles of rank $m$ (over $\mathbb{Z}/p$) one builds the algebraic stack $ZF$ of flagged F-zips (with $\text{rk} D_i = n_i$ and just as we have fixed these ranks we fix whether or not we have a symplectic or orthogonal bundle). If we only have an incomplete (but still self-dual) flag extending $C^\bullet$ we shall speak of a partially flagged F-zip and we can do the same construction getting a partial flag extending $D_\bullet$. A partially flagged F-zip is stable if for every $i$ and every $k$ we have that $G_{i'_r} \cap C^k + C^{k+1}$ is equal to some $E_j$ or in relevant cases (middle part of) the flip of $E_\bullet$ (where $i$ and $k$ are chosen so that $G_{i'_r}, C^k$ and $C^{k+1}$ are defined).

If the rank of the flagged orthogonal F-zip $(M, E, G)$ is even we can replace both $E$ and $G$ by their flips and it is easy to see that we get a new flagged F-zip which will be called the flip of the flagged F-zip.

Fixing the rank, $n$, of $M$ and the type (symplectic or orthogonal) the relative position of the flags $C^\bullet$ and $D^\bullet$ is, by Proposition 3.1, described by an element $w$ of $W_n^{-2}$, $W_{n-1}^{-2}$, and $W_n^D$ when the F-zip is symplectic, orthogonal with $n$ odd, and orthogonal with $n$ even respectively. This defines locally closed substacks $ZF_w$ of $ZF$ consisting of those flags (of fixed type and ranks $w$) of relative position $w$. We now also fix the sequence $\underline{w} = (0 = n_0 < n_1 < \cdots < n_r = n)$ where we demand that $\text{rk}(D_i) = n_i$ (in particular self-duality forces $n_{i+1} - n_i = n_{r-i} - n_{r-i-1}$) and let $w_0$ be the element of the appropriate Weyl group (as subgroup of $S_n$) that takes the first $n_0$ integers to the last $n_0$ (in order), the next $n_1 - n_0$ integers to the $n_1 - n_0$ last (still in order) and so on (that is, it sends the interval $[n_i + 1, n_{i+1}]$ to $[n + 1 - n_{i+1}, n - n_i]$ preserving order).

**Construction:** Given an element $w$ in the appropriate group we define a flagged F-zip over Spec $\mathbb{F}_p[x_{ij}]_{1 \leq i < j \leq n}/I$ as follows, where generators of the ideal $I$ are specified below:

- $e_i$, $i = 1, \ldots, n$, is a basis for $M$ with $\langle e_i, e_j \rangle = \delta_{i,n+1-j}$ for $i \leq j$.
- $C^i$ has $e_1, \ldots, e_i$ as a basis and $D_i$ has $e_{w^{-1}(1)}, \ldots, e_{w^{-1}(i)}$ as a basis.
For \( n_k < i \leq n_{k+1} \) we have \( \varphi_k(e_i) = e_{w^{-1}w_k(i)} + \sum_{w_k(j) < i} x_{ij} e_j \mod D_{n-r-k-1} \).

- The matrix \( \text{Id}_n + (x_{ij}) \) is symplectic or orthogonal respectively with respect to the scalar product of the basis \( e_1, \ldots, e_n \).
- \( x_{ij} = 0 \) unless \( i < j \), where \( i < j \) precisely when \( w^{-1}(i) > w^{-1}(j) \) for \( n_t < j < i \leq n_{t+1} \) for some \( \ell \) with \( n_\ell < n/2 \).

When \( n \) is odd, then we can define another flagged F-zip over \( \text{Spec} \mathbb{F}_p[x_{ij}]_{1 \leq i < j \leq n}/I \) with the same definition except that we let \( \varphi(e_{(n+1)/2}) = -e_{(n+1)/2} + \sum_{w_j(j) < (n+1)/2} x_{ij} e_j \mod D_t \), where \( x_{ii} = 0 \). Let \( T \) consist of the diagonal automorphisms \( e_i \mapsto t_i e_i \), where \( t_i \cdot t_{n+1-i} = 1 \) and \( t_{(n+1)/2} = 1 \) if \( n \) is odd. It transforms a \( \varphi \) into another F-zip with \( x_{ii} = t_{-w^{-1}w_k(i)}^{-1} \). As the endomorphism of \( T \) given by \( (t_i \mapsto t_{-w^{-1}w_k(i)}^{-1}) \) is separable (inducing \( -w^{-1}w_g(i) \) on the Lie algebra) we get that the map from the substack of \( \mathcal{ZF}_w \) with \( x_{ii} = 1 \) for \( i \neq (n+1)/2 \) and \( x_{ii} = \pm 1 \) if \( i = (n+1)/2 \) to \( \mathcal{ZF}_w \) is an equivalence and hence we may restrict to it.

It remains to show that we may remove the \( x_{ij} \) with \( n_t < j < i \leq n_{t+1} \) and \( w^{-1}(j) < w^{-1}(i) \).

Under those assumptions, the change of basis \( e_i' = e_i + \lambda e_j \), \( e_j' = e_j - \lambda e_i \) with \( \lambda = n + 1 - x \), preserves both flags.

We now have

\[
\varphi_k(e_i') = \varphi_k(e_i + \lambda e_j) = e_{w^{-1}w_k(i)} + \sum_{w_k(j) < i} x_{ij} e_j + \lambda (e_{w^{-1}w_k(j)} + \sum x_{ij} e_j)
\]

and we try to choose \( \lambda \) such that the coefficient in front of \( e_{w^{-1}w_k(j)} \) is equal to zero. This gives a monic equation in \( \lambda \) with \( \lambda^2 \) as top term and hence defines a surjective finite flat covering.

We can repeat this construction in a way so that we take the largest \( i \) and \( j \) first in order for subsequent operations not to reintroduce non-zero coefficients in positions where they have been removed. At the end we get the chosen F-zip on \( Y_w \) which shows fully faithfulness as each step is fully faithfully flat.

\[ \square \]

### 5 The Hodge discriminant

We shall now introduce a discriminant which is a Hodge theoretic description of Ogus’ crystalline discriminant (defined under slightly more general circumstances). For that we need the determinant of a complex in the sense of Mumford and Knudsen (cf., [KM76]). Recall that in order to get the signs right the determinant is a graded line bundle, i.e., a pair \((m, L)\) where \( m \) is an integer and \( L \) a line bundle. This is then used in the commutativity isomorphism \( L \otimes M \rightarrow M \otimes L \) where the sign \((-1)^{\ell m}\) is used, where \( \ell \) and \( m \) are the degrees of \( L \) and \( M \) respectively. The coherence conditions proved in [loc. cit.] then shows that we get an unambiguous isomorphism between tensor products of the same graded line bundles in different order.

We shall need one property of the determinant beyond those of [loc. cit. Def. 4]: If, for a perfect complex \( C \) of \( \mathcal{O}_S\)-modules, \( S \) a scheme, we let \( C^* := \text{RHom}_S(C, \mathcal{O}_S) \), then we have a canonical isomorphism \( \rho_C : \det(C)^* \overset{\sim}{\rightarrow} \det(C^*) \) functorial for quasi-isomorphisms. Indeed,
Recall (cf., [Il79, §2.1]) the Cartier isomorphism \( H \) taking determinants we get (cf., [loc. cit., Rmk after Thm. 2] for an explication) an isomorphism

\[
(L \otimes M) \otimes (M^* \otimes L^*) = L \otimes (M \otimes M^*) \otimes L^* \xrightarrow{id \otimes ev_M \otimes id} L \otimes \mathcal{O}_S \otimes L^* = L \otimes L^* \to \mathcal{O}_S,
\]

where we have used the above sign rule for the permutation. The unicity (as well as direct computation) also gives that we have a commutative diagram

\[
\begin{array}{ccc}
\det(C^*) & \xrightarrow{\rho_C} & \det(C)^* \\
\downarrow & & \downarrow \\
\det(C) & \xrightarrow{\det(ev_C)} & \det(C),
\end{array}
\]

where \( ev_C : C \to C^{**} \) is the evaluation map (and similarly for \( ev_{det(C)} \)). If \( \mathcal{E} \to \mathcal{F} \to \mathcal{G} \to \) is a distinguished triangle of perfect complexes we have a distinguished triangle \( \mathcal{G}^* \to \mathcal{F}^* \to \mathcal{E}^* \to \) and the resulting identification

\[
(\det \mathcal{E} \otimes \det \mathcal{G})^* = \det(\mathcal{F})^* = \det(\mathcal{F}^*) = \det(\mathcal{G}^*) \otimes \det(\mathcal{E}^*)
\]

is then a special case of the above identification.

Now, let \( \pi : X \to S \) be a smooth and proper map of schemes of pure relative dimension \( n \) over a base \( S \) of positive characteristic \( p \neq 2 \). Let \( L \) be the determinant of \( R\pi_*\Omega^*_X/S \) (which exists as \( R\pi_*\Omega^*_X/S \) is a perfect complex). By Poincaré duality we have a canonical isomorphism

\[
(R\pi_*\Omega^*_X/S)^* \to R\pi_*\Omega^*_X/S[-2n]
\]

which upon taking determinants gives an isomorphism

\[
L^* \xrightarrow{p} \det(R\pi_*\Omega^*_X/S[-2n]) \Rightarrow L^{(-1)2n} = L.
\]

Now, Poincaré duality gives a symmetric pairing and by [Il] this gives a perfect symmetric pairing \( L \otimes L \Rightarrow \mathcal{O}_S \). On the other hand, the naive truncations of the de Rham complex give rise to distinguished triangles

\[
R\pi_*\Omega^{i+1}_{X/S} \to R\pi_*\Omega^i_{X/S} \to R\pi_*\Omega^i_{X/S}[-i] \to .
\]

Taking determinants we get (cf., [loc. cit., Rmk after Thm. 2] for an explication) an isomorphism

\[
\mathcal{L} \Rightarrow \bigotimes_{i=0}^n \det(R\pi_*\Omega^i_{X/S})^{(-1)^i}.
\]

Similarly, we may use the canonical truncations to get a distinguished triangle

\[
R\pi_*\mathcal{H}^i(\Omega^*_X/S)[-i] \to R\pi_*\tau_{\geq i}\Omega^*_X/S \to R\pi_*\tau_{\geq i+1}\Omega^*_X/S \to .
\]

Recall (cf., [Il87, §2.1]) the Cartier isomorphism \( \mathcal{H}^i(F_{X/S}, \Omega^*_X/S) = \Omega^i_{X(p)/S} \), where \( F_{X/S} : X \to X(p) \) is the relative Frobenius map. Applying \( R\pi^*(p) \), with \( \pi^*(p) : X(p) \to X \) the structure map, we get \( R\pi_*\mathcal{H}^i(\Omega^*_X/S) = R\pi^*(p)\Omega^i_{X(p)/S} = R\pi^*(p)F_{X/S}^i\Omega_{X/S}^i \). Finally using the base change formula \( R\pi^*(p)LF_S^*F_S^*R\pi_* \) we get an identification of derived functors

\[
LF_S^*R\pi_*\Omega^*_X/S \Rightarrow R\pi_*\mathcal{H}^i(\Omega^*_X/S).
\]

1The reader who feels the need to recall the definition of naive and canonical truncations could profitably consult [Il04].
Combining these formulas and taking determinants we obtain an isomorphism

$$\mathcal{L} \mapsto \bigotimes_{i=n}^{0} \det(LF_{\mathcal{L}}^{i} R\pi^{*} \Omega^{i}_{X/S})(-1)^{i} = F_{S}^{*} \left( \bigotimes_{i=n}^{0} \det(R\pi^{*} \Omega^{i}_{X/S})(-1)^{i} \right).$$

(3)

We may then permute the last tensor product to get an isomorphism

$$F_{S}^{*} \left( \bigotimes_{i=n}^{0} \det(R\pi^{*} \Omega^{i}_{X/S})(-1)^{i} \right) \Rightarrow F_{S}^{*} \left( \bigotimes_{i=0}^{n} \det(R\pi^{*} \Omega^{i}_{X/S})(-1)^{i} \right).$$

Comparing the obtained formulas for $\mathcal{L}$ and $F_{S}^{*} \mathcal{L}$ we get an isomorphism $\varphi: \mathcal{L} \mapsto F_{S}^{*} \mathcal{L}$, in other words we have an $F$-structure on $\mathcal{L}$. Now, the isomorphism of (3) is compatible with duality (if we use the tensor product of the Hodge duality isomorphisms on the right hand side) and so is (3) because the Cartier isomorphism is multiplicative. This implies that $\varphi$ is compatible with the pairing on $\mathcal{L}$. We may now consider the sheaf $L$ (in the étale topology on $S$) of fixed points under $\varphi$ and we know that $\mathcal{L} = L \otimes_{F_{S}} \mathcal{O}_{S}$, so that in particular $L$ is a local system of 1-dimensional $F_{S}$-vector spaces. The pairing on $\mathcal{L}$ induces a symmetric non-degenerate pairing on $L$ and taking (locally) its discriminant gives us a locally constant function from $S$ to $F_{S}/F_{p}^{2}$. The latter group can be identified, using the Legendre symbol, with $\{ \pm 1 \}$ and we shall call the resulting function $S \rightarrow \{ \pm 1 \}$ the Hodge discriminant of $X \rightarrow S$. It clearly commutes with base change. In particular its value can be computed fibrewise.

The Hodge discriminant uses the whole cohomology of $X/S$. Often we can also work with the middle cohomology only. Indeed, if we have an orthogonal or symplectic $F$-zip $(M, C^{*}, D_{\bullet}, \varphi_{\bullet})$, we can make the same construction, identifying $\det M$ with $\det \gr^{\bullet} C^{*}$ and $\det \gr_{\bullet} D_{\bullet}$, using $\varphi$ to identify $F^{*}(\det \gr^{\bullet} C^{*})$ with $\det \gr_{\bullet} D_{\bullet}$ and finally using the induced pairing to define a discriminant for the fixed points. This yields a Hodge discriminant for the $F$-zip $(M, C^{*}, D_{\bullet}, \varphi_{\bullet})$.

Recall now (cf., [Og82, Def. 3.1]) the definition of Ogus' crystalline discriminant: Given an orthogonal or symplectic $F$-crystal $M$ over an algebraically field $k$ we get an induced $F$-crystal structure on $\det M$ for which $F$ is a power of $p$, $p^{m}$ say, times an isomorphism. Dividing by $p^{m}$ and taking fixed points we get a $\mathbb{Z}_{p}$-module of rank 1 with a perfect pairing. Taking its discriminant and reducing modulo $p$ gives us an element of $F_{p}^{*}/F_{p}^{2}$, the crystalline discriminant.

Before stating how these discriminants are related we recall that for a proper smooth variety of pure dimension $n$ over a field $k$ of positive characteristic $p$ we have the $\ell$-adic Betti number $b_{n}(X)$ (which is the same as the rank of the $n$’th crystalline cohomology group), the number $b'_{n}(X) := \dim H^{n}_{dR}(X/k)$ and the Hodge numbers $h^{ij}$ satisfying

$$b_{n}(X) \leq b'_{n}(X) \leq \sum_{i+j=n} h^{ij}(X).$$

If $b'_{n}(X) = \sum_{i+j=n} h^{ij}(X)$ then the $E_{2}^{i,j}$-term of the Hodge-to-de Rham spectral sequence equals the $E_{\infty}^{i,j}$-term for all $i + j = n$. By dimension counting this then implies the same thing for the $E_{1}^{i,j}$-term of the conjugate spectral sequence. Hence the Hodge and conjugate filtrations on $H^{n}_{dR}(X/k)$ together with the Cartier isomorphisms give an $F$-zip structure on $H^{n}_{dR}(X/k)$. This is symplectic if $n$ is odd and orthogonal for $n$ even.

**Proposition 5.1** Suppose that $X$ is a smooth and proper variety of pure dimension $n$ over a field $k$ of positive characteristic $p$.

i) Assume that $b'_{n} := \dim_{k} H^{n}_{dR}(X/k) = \sum_{i+j=n} h^{ij}(X)$. The Hodge discriminant of $X$ is equal to $(\frac{\chi}{p})(\chi^{b'_{n}}/2)$ times the Hodge discriminant of the $F$-zip $H^{n}_{dR}(X/k)$, where $\chi$ is the crystalline (étale) Euler characteristic of $X$. If $n$ is odd the Hodge discriminant is equal to $(-1)^{n/2}$.

ii) If $b_{n}(X) = \sum_{i+j=n} h^{ij}(X)$, then the Hodge discriminant of the $F$-zip $H^{n}_{dR}(X/k)$ is equal to Legendre symbol of the crystalline discriminant of the $F$-crystal $H^{n}_{cris}(X/W)$.
Proof: We start with the easily proven fact that if \( \xrightarrow{} X^0 \xrightarrow{} Y^0 \xrightarrow{} Z \xrightarrow{} X \) is a distinguished triangle of complexes (over a field) such the induced map \( H^n(Z) \to H^{n+1}(X^0) \) is zero, then we get a diagram, all of whose rows and columns are distinguished,

\[
\begin{array}{cccccc}
\tau_{\leq n}X^0 & \xrightarrow{} & \tau_{\leq n}Y^0 & \xrightarrow{} & \tau_{\leq n}Z & \xrightarrow{} & (\tau_{\leq n}X^0)[1] \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
X^0 & \xrightarrow{} & Y^0 & \xrightarrow{} & Z & \xrightarrow{} & X^0[1] \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\tau_{> n}X^0 & \xrightarrow{} & \tau_{> n}Y^0 & \xrightarrow{} & \tau_{> n}Z & \xrightarrow{} & (\tau_{> n}X^0)[1]
\end{array}
\]

Note furthermore that it is one of the properties of the Knudsen-Mumford determinant (cf., [KM76, Def 4]) that the two ways of using this diagram to get an isomorphism

\[
\det(Y) \xrightarrow{} \det(\tau_{\leq n}X^0) \otimes \det(\tau_{> n}X^0) \otimes \det(\tau_{\leq n}Z) \otimes \det(\tau_{> n}Z) \quad (4)
\]

give the same result.

The degeneration of the Hodge to de Rham spectral sequence and that of the conjugate spectral sequence both at total degree \( i + j = n \) implies that the necessary conditions are fulfilled to apply this and thus allow us to conclude that we have distinguished triangles:

\[
\begin{align*}
\tau_{< n}R\Gamma(X, \Omega^{\geq i+1}) & \xrightarrow{} \tau_{< n}R\Gamma(X, \Omega^{\geq i}) \xrightarrow{} \tau_{< n}R\Gamma(X, \Omega^0[-i]) \\
\tau_{> n}R\Gamma(X, \Omega^{\geq i+1}) & \xrightarrow{} \tau_{> n}R\Gamma(X, \Omega^{\geq i}) \xrightarrow{} \tau_{> n}R\Gamma(X, \Omega^0[-i]) \\
\tau_{< n}R\Gamma(X, \mathcal{H}^i[-i]) & \xrightarrow{} \tau_{< n}R\Gamma(X, \tau_{\geq i}\Omega^0) \xrightarrow{} \tau_{< n}R\Gamma(X, \tau_{\geq i+1}\Omega^0) \\
\tau_{> n}R\Gamma(X, \mathcal{H}^i[-i]) & \xrightarrow{} \tau_{> n}R\Gamma(X, \tau_{\geq i}\Omega^0) \xrightarrow{} \tau_{> n}R\Gamma(X, \tau_{\geq i+1}\Omega^0)
\end{align*}
\]

This gives us expansions

\[
\begin{align*}
\det(\tau_{< n}R\Gamma(X, \Omega^0)) &= \bigotimes_{i=0}^n \det(\tau_{< n-i}R\Gamma(X, \Omega^i))^{(-1)^i} \\
\det(\tau_{> n}R\Gamma(X, \Omega^0)) &= \bigotimes_{i=0}^n \det(\tau_{> n-i}R\Gamma(X, \Omega^i))^{(-1)^i} \\
\det(H^n(X, \Omega^0)) &= \bigotimes_{i=0}^n \det(H^{n-i}(X, \Omega^i))^{(-1)^i}
\end{align*}
\]

and

\[
\begin{align*}
\det(\tau_{< n}R\Gamma(X, \Omega^0)) &= \bigotimes_{i=n}^\infty \det(\tau_{< n-i}F^*\Gamma(X, \Omega^i))^{(-1)^i} \\
\det(\tau_{> n}R\Gamma(X, \Omega^0)) &= \bigotimes_{i=n}^\infty \det(\tau_{> n-i}F^*\Gamma(X, \Omega^i))^{(-1)^i} \\
\det(H^n(X, \Omega^0)) &= \bigotimes_{i=n}^\infty \det(F^*H^{n-i}(X, \Omega^i))^{(-1)^i},
\end{align*}
\]

where \( F = F_{\text{Spec}k} \).

Now, we also have an expansion

\[
\det(\Gamma(X, \Omega^0)) = \det(\tau_{< n}R\Gamma(X, \Omega^0)) \otimes \det(H^n(X, \Omega^0)) \otimes \det(\tau_{> n}R\Gamma(X, \Omega^0)). \quad (5)
\]

We have already given the left hand side an \( F \)-structure and the isomorphisms above give \( F \)-structures on each multiplicand of the right hand side. However, it follows from (4) and the fact
that the tensor product on graded line bundles is symmetric monoidal that those two $F$-structures are the same.

As for the self-pairing we have that the duality induces isomorphisms $(\tau_{c,t} R\Gamma(X,\Omega^*_X))^* = \tau_{c,t} R\Gamma(X,\Omega^*_X)[-2n]$ and $H^n(X,\Omega^*_X)^* = H^n(X,\Omega^*_X)$. This means that in the decomposition of $\tau_{c,t} R\Gamma(X,\Omega^*_X)$ the self-pairing on the left corresponds to a pairing on the right which pairs the first factor to the third and the second to itself. This is compatible with semi-linear structure so that when we take fixed points under $F$ we get a decomposition $L = L^e \otimes L^o \otimes L^s$, with $L^e$ and $L^o$ being paired to each other and $L^s$ to itself. Taking the signs into account we get that the discriminant of $L$ is equal to $(\frac{1}{p})^{\dim L^s}$ times the discriminant of $L^e$. However, the dimension of $L^e$ is equal to the dimension of $\tau_{c,n} R\Gamma(X,\Omega^*_X)$ which is $(\chi - b'_n)/2$. Of course, when $n$ is odd $L^e$ is trivial. This concludes the proof of i).

As for ii) we are reduced by i) to showing that the Hodge discriminant of $H^d_{cris}(X/k)$ is equal to the crystalline discriminant of $H^d_{cris}(X/W)$. By the Mazur-Ogus result [BO78, Appendix] we may choose a basis $e_1^1, \ldots, e_{p_{d_e}}^1, e_2^1, \ldots, e_{p_{d_e}}^2$ of $H^d_{cris}(X/W)$ such that $F_{cris}^*(\cdot)$ is divisible by $p^s$ and such that the Hodge filtration of $H^d_{cris}(X/k)$ is given by $H_i = \sum_{j \leq i} \sum_{1 \leq k \leq h} k\mathfrak{m}_k^{(j)}$, the conjugate filtration is given by $H_i = \sum_{j \leq i} \sum_{1 \leq k \leq h} \mathfrak{m}_k^{(j)} F_{cris}^*(\cdot)$ and the inverse Cartier isomorphism is given by $\{p^{-1} F\}$. Unraveling definitions then gives ii).

**Remark:** As the proposition shows, under suitable conditions the Hodge discriminant is equivalent to the crystalline discriminant. We justify introducing new notation since it would be somewhat artificial to use “crystalline” in a situation where it is not relevant; moreover, it makes sense more generally, for instance in the case of Enriques surfaces in characteristic two. Please note that we have defined the Hodge discriminant to be the Legendre symbol applied to an element rather than the element itself. (Of course the Legendre symbol gives a bijection $\{\pm 1\}$ so no information is lost.) The reason for this convention is to make the formulas of Proposition 5.2 as nice as possible; otherwise that formula would have to involve the inverse of the isomorphism provided by the Legendre symbol.

The further properties of the Hodge discriminant will differ somewhat depending on whether $H$ has even or odd dimension, so we shall discuss each case separately.

### 5.1 The Hodge discriminant of an orthogonal flagged $F$-zip

We now derive a formula for the Hodge discriminant of an orthogonal flagged $F$-zip. In the odd-dimensional case we need one more notion. Hence consider a flagged orthogonal $F$-zip $(H, C^*, D_\bullet, \varphi_*)$ of dimension $2m + 1$. We get two induced isomorphisms

$$C^{m+1}/C^m \iff C^{m+1} \cap D_{m+1}/C^m \cap D_m \Rightarrow D_{m+1}/D_m$$

and together with the inverse Cartier isomorphism they give rise to an isomorphism

$$F^*(C^{m+1}/C^m) \Rightarrow C^{m+1}/C^m.$$ 

On the other hand, we also have a pairing on $C^{m+1}/C^m$ induced from that of $H$ and it is compatible with $F^*(C^{m+1}/C^m) \Rightarrow C^{m+1}/C^m$. Hence, we get an $F_p^*/F_p^{2*}$-valued discriminant by taking fixed points. We shall call it the *middle discriminant*.

**Proposition 5.2** Let $(H, C^*, D_\bullet, \varphi_*)$ be an orthogonal flagged $F$-zip.

i) Assume $H$ has dimension $2m + 1$ of type $w \in W^C_m$. Then the Hodge discriminant equals $(-1)^{n_s} \text{disc}(w) \left(\frac{4}{p}\right)$, where $d = (-1)^{n_s} d'$ with $d'$ the middle discriminant, and $s = |r/2|$.

ii) Assume $H$ has dimension $2m$ of type $w \in W^D_m$. Then the Hodge discriminant equals $(-1)^{n_s} \left(\frac{4}{p}\right)^m \text{disc}(w)$, where $s = |r/2|$.

**Proof:** For the odd case we may assume by Proposition 4.1 that the $F$-zip is associated to a $k$-point of $Y_w$, i.e., there is a basis $e_1, \ldots, e_{2m+1}$ for $H$ with $\langle e_i, e_j \rangle = \delta_{i,2m+2-j}$. $F_i = \sum_{j \leq i} k e_j$,
and \( D_t = \sum_{j=1}^{g} \kappa e_{w^{-1}(j)} \) with \( \varphi_k \) acting as specified by the construction of the \( F \)-zip on \( Y_w \). This implies that
\[
\varphi_k(e_{n+1}^{-1}w_1) = \epsilon e_{w^{-1}w_1(n+1)} = \epsilon e_{w^{-1}w_1(2n+2)} = \cdots = \epsilon e_{w^{-1}w_1(n+1)}.
\]
Here \( \epsilon_k = 1 \) when \( k \neq m \) and \( \epsilon_m = \pm 1 \) when the middle discriminant is a square and \(-1\) when it is not. This implies that the semi-linear map on the determinant takes \( e_1 \wedge e_2 \cdots \wedge e_{2m+1} \) to \( e_1 e_2 \cdots e_{2m+1} \). Similarly we have that \( e_1 \wedge e_2 \cdots e_{2m+1} = (-1)^m \). Now we conclude by the mod \( p \) version of [Og82] Formula 3.4] using that \( d' \) is a square precisely when \( \epsilon_m \) and that
\[
disc(w_h) = (-1)^m.
\]

The proof of the even-dimensional case is identical to the odd case except that we always have \( \epsilon_m = 1 \). \( \qed \)

## 6 K3-surfaces

Let \( N \) be a non-degenerate integral lattice. A \emph{(partial) N-marking} of a K3 surface \( X \) over a field \( k \) of positive characteristic \( p \) is an isometric embedding \( N \to \text{NS}(X) \). (We recall that for a K3-surface the Néron-Severi group \( \text{NS}(X) \) is equal to the Picard group of \( X \).) The \emph{discriminant} of the marking is the discriminant of the lattice \( N \). We shall only be interested in partial markings whose degree is prime to \( p \) and thus that will be assumed unless otherwise mentioned. We define the \emph{primitive cohomology} of an \( N \)-polarized K3 surface \( X \) as the orthogonal complement of the image of \( N \) in \( H^2_{DR}(X/k) \).

The primitive cohomology is an orthogonal \( F \)-zip with dimension vector for its Hodge filtration being \((0, 1, n-1, n)\) for some \( n \). We shall also need another type of \( F \)-zip. Hence, an \( F \)-zip with vector \((0, \ldots, 0, m, \ldots, m)\) shall be called a \emph{Tate F-zip}. Tate F-zips thus consist of an orthogonal vector space \( V \) and an orthogonal F-structure \( \varphi : F^*V \to V \). It is thus completely described by the orthogonal representation of the Galois group of \( k \) given by the action on \( V := \ker(\varphi - 1) \) on \( V \otimes_k \mathbb{F}_p \). We shall say that the Tate F-zip is \emph{split} resp. \emph{non-split} as the form on \( V \) is. Its Hodge discriminant is then \((\frac{m}{p})\), where \( d \) is the discriminant of \( V \). In these terms we have that \( H^2_{DR}(X/k) \) is the sum, as \( F \)-zip, of the primitive cohomology and \( N \otimes_k \mathbb{F}_p \) considered as a Tate F-zip.

**Definition 6.1** Let \( M \) be a stable partially flagged orthogonal or symplectic \( F \)-zip.

i) \( M \) is \emph{final} if it is complete.

ii) If \( M \) is symplectic or orthogonal of odd dimension then it is \emph{canonical} if every stable flag is a refinement of it.

iii) If \( M \) is orthogonal of even dimension it is \emph{canonical} if every stable flag is a refinement of \( M \) or possibly, when it exists, its flip.

**Example:** For a Tate F-zip its (trivial) Hodge filtration already is canonical. A final filtration is an \( \mathbb{F}_p \)-rational self-dual flag except that in case the \( \mathbb{F}_p \)-form is non-split the middle element of the flag is only defined over \( \mathbb{F}_p^2 \).

**Lemma 6.2** Let \( w \) be an element of \( W^B_m \) or \( W^D_m \). Assume that for all \( 1 \leq i, j \leq n-1 \), where we do not have \( i = j = n/2 \),

\[
r_w(i, j) = \begin{cases} 
\min(j, r_w(i, n-1) + 1) - 1 & \text{if } i < a, \\
\min(j, r_w(i, n-1)) & \text{if } i \geq a,
\end{cases}
\]

where \( a := w^{-1}(1) \) and \( n = 2m+1 \) in the \( B \)-case and \( 2m \) in the \( D \)-case. Then \( w \) is a final element and conversely the \( r_w \) for \( w \) final fulfils this condition.

**Proof:** It is clear that \( r_w(i, n-1) = \# \{ 1 \leq b \leq i \mid w(b) \leq n-1 \} \) is determined completely by \( w^{-1}(n) \) which is equal to \( n + 1 - a \). The assumed conditions on \( r_w \) then implies that the whole function is determined by \( a \) and hence so is \( w \). It is easy to verify that a final \( w \) fulfils the conditions and that there is one such element for each \( a \). \( \qed \)
Proposition 6.3 A flagged orthogonal $F$-zip of type $(0, 1, n-1, n)$ is final precisely when its type is a (twisted) final element.

Proof: Suppose that $E_\bullet$ is a final filtration and $G_\bullet$ the corresponding conjugate filtration (so that $0 \subset E_1 \subset E_{n-1} \subset E_n$ is the Hodge filtration and $0 \subset G_1 \subset G_{n-1} \subset G_n$ the conjugate filtration). For each $1 \leq i \leq n-1$ we have by assumption that for every $i$ the subspace $G_i \cap E_{n-1} + E_1$ is equal to some $E_r$ (or possibly its flip $E_r'$ if $2r = n$). Then for $1 \leq j \leq n-1$

$$G_i \cap E_j + E_1 = (G_i \cap E_{n-1} + E_1) \cap E_j = E_r \cap E_j = E_{\min(r,j)},$$

where the end result would instead be $E_{r-1}$ if $G_i \cap E_{n-1} + E_1 = E_r'$ and $j = r$. Now, $r_w(i, j) =$ dim$(G_i \cap E_j)$ and in particular $E_1 \subseteq G_i$ precisely when $i \geq w^{-1}(1)$ and thus dim$(G_i \cap E_j + E_1)$ is equal to $r_w(i, j) + 1$ if $i < w^{-1}(1)$ and $r_w(i, j)$ otherwise (supposing that we do not have $i = j = n/2$). This shows that $r_w$ fulfills the condition of Lemma 1.2 and hence $w$ is final. The converse is just a matter of tracing the argument backwards.

Recall that two orthogonal $F$-zips of type $(0, 1, n-1, n)$ are called opposite if their intersections have the smallest possible dimensions, i.e., $F_1 \not\subset E_{n-1}$.

It follows from either the description of the final elements or from the proof of the next theorem that the canonical filtrations have the form $U_1 \subset U_2 \subset \cdots \subset U_k \subset U_{n-k} \subset \cdots U_n$, where the primitive cohomology has dimension $n$. We shall call $U_{n-k}/U_k$ the middle part of the canonical filtration. It comes equipped with a quadratic form induced from that of $H^2_{dR}(X/k)$ and the Cartier isomorphism induces an orthogonal $p$-linear isomorphism of it (i.e., a Tate $F$-zip structure). The fixed points under the Cartier isomorphism then give an $F_p$-rational structure on the middle part and the quadratic form induces a quadratic form on it. We shall say that the canonical filtration is split resp. non-split according to as that form is.

Theorem 6.4 Let $X$ be a polarised K3 surface of degree prime to $p$ over a field $k$ of characteristic $p > 0$ and let $H$ be its primitive Hodge cohomology of dimension $n$ with $m := \lceil n/2 \rceil$. Then $H$ has a canonical filtration. Any final filtration is obtained from the canonical one by choosing a complete $F$-stable filtration and if $k$ is separably closed it has a final filtration. All final filtrations have the same (twisted) final type.

Proof: We start with the (induced) Hodge filtration $0 \subset E_1 \subset E_{n-1} \subset E_n = H$ on the primitive cohomology with conjugate filtration $0 \subset F_1 \subset F_{n-1} \subset F_n = H$ with $F_1 = E_{n-i-1}$. If $F_1 = E_1$ then the two filtrations coincide and then this partially flagged $F$-zip is canonical as one easily checks. If $F_1 \neq E_1$ then we consider the image of $F_1$ in $E_n/E_{n-1}$. If this image is non-zero then the Hodge filtration and the conjugate one are opposite and we get a stable and hence canonical flagged $F$-zip. So suppose that $F_1$ has non-zero image in $E_{n-1}/E_1$. We can apply Frobenius and use the Cartier isomorphism to get the image $F_2$ in $E_{n-1}/E_1^p = E_{n-1}/F_1$. We then add to our flag the inverse image $F_2$ of $F_2$ in $E_{n-1}$. Now $F_1$ is totally isotropic, hence its image in $E_{n-1}/E_1$ is as well and as the Cartier isomorphism is multiplicative for the wedge product, so is $F_2$ and therefore $F_{n-2} := F_2^\perp$ contains $F_2$. We then continue this process: if $F_2$ is not contained in $E_{n-1}$ then we have obtained a stable filtration. This is also the case if $E_1 \subset F_2$. On the other hand if $F_2 \subset E_{n-1}$ and $F_2 \cap E_1 = \{0\}$ then we consider the image of $F_2$ in $E_{n-1}/E_1$ and transfer via $F$ and the Cartier isomorphism the image to $F_{n-1}/F_1$. Note that each stage of the induction $F_{n-1} \subset E_{n-1}$ precisely when $E_1 \subset F_1$ and thus we will not be forced to introduce any new elements to the flag because of the position of $F_{n-1} := F_{n-1}^\perp$. It is clear that this process stops and gives a canonical flag. That a canonical filtration can be extended to a final filtration and that they are all of the same type is easy and similar to the abelian case, see [EG10, Def-Lemma 2.11].

7 Canonical filtrations versus the height and Artin invariant

A natural question is now what the type of the final filtration means geometrically. The following theorem will provide the answer. Recall that we can define two invariants for a K3-surface $X$
in positive characteristic, the height and the so-called Artin invariant. The height \( h(X) \) is the height of the formal Brauer group, a smooth formal group of dimension 1. This invariant assumes values \( 1 \leq h < 10 \) or \( h = \infty \); in the latter case the formal Brauer group is the formal additive group. The Artin invariant \( \sigma_0 \) can be defined for supersingular K3-surfaces, i.e. those with \( h = \infty \) by putting \( \text{disc}(H^2(X, \mathbb{Z}_p(1))) = p^{2\sigma_0} \), cf., [Ar74]. We then have \( 1 \leq \sigma_0 \leq 10 \). The case \( h = 1 \) is the generic finite height case and \( \sigma_0 = 10 \) is the generic supersingular case.

These invariants can be detected by the crystalline cohomology. We therefore recall first some facts on crystalline cohomology and the relation with de Rham-cohomology (cf., [BO73, Thm 8.26]).

Let \( W(k) \) be the ring of Witt vectors of \( k \) and let \( \sigma \) be the map on \( W(k) \) induced by the Frobenius map on \( k \). The second crystalline cohomology group \( \mathcal{H} := H^2(X/W(k)) \) is a free \( W(k) \)-module of rank 22 and is provided with a \( W(k) \)-linear map \( F: \sigma \ast \mathcal{H} \to \mathcal{H} \). We have a natural isomorphism from \( \mathcal{H}/p\mathcal{H} \Rightarrow H^2_{\text{dR}}(X/k) \) and by base change by the Frobenius map on \( k \) we get an isomorphism \( \sigma^\ast \mathcal{H}/p\sigma^\ast \mathcal{H} \Rightarrow H^2_{\text{dR}}(X^{(p)}/k) \). If we put \( \mathcal{H}_i := F^{-i}p^{2-i}\mathcal{H} \) for \( i = 0, 1, 2 \), then the images \( H_i \) of \( \mathcal{H}_i \) in \( \sigma^\ast \mathcal{H}/p\sigma^\ast \mathcal{H} \) give the Hodge filtration on \( H^2_{\text{dR}}(X^{(p)}/k) \) (with \( E_0 = H_0 \), \( E_{n-1} = H_1 \) and \( E_n = H_2 \) in the notation of the proof of Thm 6.4) while the images of the \( \mathcal{H}_i^\ast := p^{-i}F\mathcal{H}_{2-i} \) in \( H^2_{\text{dR}}(X/k) \) give the conjugate filtration. Finally, the inverse Cartier isomorphism is induced by the map \( p^{-1}F: \mathcal{H}_{2-i} \to \mathcal{H}_i^\ast \).

Recall that we choose a marking by giving an isometric embedding \( N \to \text{NS}(X) \). In particular we have a discriminant \( d \) of the marking.

**Theorem 7.1** Let \( X \) be a polarized K3 surface of degree prime to \( p \) over a field \( k \) of characteristic \( p > 0 \) and let \( H \) be its primitive Hodge cohomology of dimension \( n \) with \( m := \lceil n/2 \rceil \).

i) If \( X \) has finite height with \( 2h < n \), then \( H \) has final type \( w_h \) or \( w_h' \). When \( n \) is even it is \( w_h \), if the middle part is non-split and \( w_h' \) if it is split.

ii) If \( X \) has finite height \( n = 2 \), then \( H \) has final type \( w_m' \).

iii) If \( X \) is supersingular with Artin invariant \( \sigma_0 < n/2 \), then \( H \) has final type \( w_{n-1-\sigma_0} \) or \( w_{n-1-\sigma_0}' \). When \( n \) is even it is \( w_{n-1-\sigma_0} \) if the middle part is split and \( w_{n-1-\sigma_0}' \) if it is non-split.

iv) If \( X \) is supersingular with Artin invariant \( \sigma_0 = n/2 \), then \( H \) has final type \( w_{n-1} \).

v) The Hodge discriminant of \( H \) is equal to \( (\frac{n}{d}) \), where \( d \) is the discriminant of the marking.

**Proof:** Note that because the discriminant of the marking is prime to \( p \), our space \( \mathcal{H} := H^2(X/W(k)) \) splits into the orthogonal direct sum \( N^\perp \bigoplus(W(k) \otimes N) \), where \( N \) embeds using the crystalline Chern class and a similar statement is true for Hodge cohomology. This gives in particular that the Hodge discriminant of \( H^2_{\text{dR}}(X/k) \) is the product of the Hodge discriminant of the primitive part and the Legendre symbol of the discriminant of \( N/pN \). By a theorem of Bloch and Ogus (cf., [Og83, Thm 4.9]), it is equal to \((-1)^{22-1} \) and this together with the relation between the Hodge and crystalline discriminants gives v).

Now, if we perform our construction of the canonical filtration on all of \( H^2_{\text{dR}}(X/k) \), it will be performed separately on the reduction modulo \( p \) of \( N^\perp \) and \( W(k) \otimes N \). Furthermore it will be completely trivial on the second factor having a canonical flag consisting only of the zero subspace and the full space. Hence we may as well work with the full crystalline and de Rham cohomologies rather than their primitive parts and we shall do exactly that. Thus now \( H \) may be identified with \( \mathcal{H}/p\mathcal{H} \). With these results in mind we shall now consider the different cases.

**Case 1.** Consider first the case of finite height \( h \). Then \( \mathcal{H} \) splits as an orthogonal \( F \)-stable direct sum

\[ M_{1/h} \bigoplus W(k)^{22-2h}(1) \bigoplus M_{2-1/h} . \]

Here \( M_{1/h} \) is the Dieudonné module with basis \( e_1, e_2, \ldots, e_{h-1} \) where \( F_1 = p^2 f_{i-1} \) for \( i = 2, \ldots, h-1 \) and \( F_1 = e_{h-1} \). Further, \( W(k)^{22-2h} \) is free of rank \( 22-2h \) with \( F \) acting as \( p \) on a basis. Finally, \( M_{2-1/h} \) is the dual \( M_{1/h}^\ast \) of \( M_{1/h} \) as Dieudonné module twisted once (i.e., the Frobenius map is multiplied by \( p \)). In particular, \( M_{2-1/h} \) has a basis \( f_1, f_2, \ldots, f_{h-1} \) with \( F f_i = pf_{i+1} \) for \( i = 1, \ldots, h-2 \) and \( F f_{h-1} = p^2 f_1 \). Furthermore, we have an orthogonal decomposition \( M_{1/h} \bigoplus M_{2-1/h} \perp W(k)^{22-2h}(1) \) which again means that the Hodge and conjugate filtrations
will be a direct sum of those of the summands. As before the filtrations on the \( W(k)^{22-2h}(1) \) factor will be trivial and we hence may restrict to the other factor and will put \( \mathcal{H} \) equal to \( M_{1/h} \bigoplus M_{2-1/h} \). There the pairing will be given by identifying \( M_{2-1/h} \) with the dual of \( M_{1/h} \). From the description above we conclude that

\[
(M_{1/h})_1 = pW_{e_1} + W_{e_2} + \cdots + W_{e_{h-1}},
\]

\[
(M_{2-1/h})_1 = M_{2-1/h},
\]

\[
(M_{1/h})_0 = p^2W_{e_1} + pW_{e_2} + \cdots + pW_{e_{h-1}},
\]

\[
(M_{2-1/h})_0 = pWf_1 + \cdots + pWf_{h-2} + Wf_{h-1}.
\]

This implies that \( H_0 \) has \( \mathcal{J}_{h-1} \) as a basis and \( H_1 \) has \( \mathcal{E}_{2}, \ldots, \mathcal{E}_{h-1}, \mathcal{F}_{1}, \ldots, \mathcal{F}_{h-1} \) as a basis. Similarly, we get that \( H_0^c \) has \( \mathcal{E}_{h-1} \) as a basis and \( H_1^c \) has \( \mathcal{E}_{1}, \ldots, \mathcal{E}_{h-1}, \mathcal{F}_{1}, \ldots, \mathcal{F}_{h-2} \) as a basis and we also see that \( C^{-1}: F^*(H_1/H_0) \to H_1^c/H_0^c \) takes \( \mathcal{E}_i \) to \( \mathcal{E}_{i-1} \) for \( 1 \leq i \leq h-1 \) and \( \mathcal{F}_i \) to \( \mathcal{F}_{i+1} \) for \( 0 \leq i \leq h-2 \).

Now, as we saw during the construction of the canonical filtration we do not need to introduce \( U_{n-1} := U_{l-1} \) of our desired filtration at each stage of the construction but can do it when the construction is finished. From the description above it follows that \( H_0 + H_0^c = k\mathcal{E}_{h-1} + k\mathcal{F}_{h-1} \). Transferring by the Cartier isomorphism forces us to add \( k\mathcal{E}_{h-2} + k\mathcal{E}_{h-1} \) to the refinement of the conjugate filtration. Continuing one sees that all the \( k\mathcal{E}_{h-i} + \cdots + k\mathcal{E}_{h-1} \) for \( i \leq h \) must be added to the canonical filtration. Then also their annihilators \( k\mathcal{F}_{n-i} + \cdots + k\mathcal{F}_{h-1} + M_{l/h} \) must be added. We thus get a canonical filtration with the property that \( k^{22-2h} = W(k)^{22-2h}(1) \) maps isomorphically to the quotient of the \( h \)'th step in the filtration. We can complete such a canonical flag by adding a complete self-dual flag of \( W(k)^{22-2h}(1) \) which is fixed under \( p^{-1}F \) i.e., an \( \mathbb{F}_p \)-rational such flag. By comparing our zip to the standard case of Proposition 5.2 and the form of the final elements one sees directly that these are of type \( w_h \) or \( w'_h \). To decide whether the form on \( \mathbb{F}_p^{22-2h} \) is split or not we interpret its discriminant in terms of the crystalline discriminant (cf., [a19]), i.e., the discriminant of the fixed points of \( p^{2h-2}F \) on \( \Lambda^{22-2h}(W(k)^{22-2h}(1)) \) multiplied by \((-1)^{11-h} \). As \( \mathcal{H} \) splits up as the orthogonal direct sum of \( W(k)^{22-2h}(1) \) and a hyperbolic space on \( M_{1/h} \), we see that the crystalline discriminant of \( \mathcal{H} \) equals the product of \((-1)^h \) and the crystalline discriminant of \( W(k)^{22-2h}(1) \). It follows from Proposition 5.2 that if the type is \( w \), then the Hodge discriminant is \(-\left(\frac{w}{p}\right)^{11} \text{disc}(w)\). Now, from the Bloch-Ogus theorem and what we just proved we get that the Hodge discriminant of the middle part is \(-\left(\frac{w}{p}\right)^{11} \text{disc}(w)\) as it is split precisely when its Hodge discriminant is \(-\left(\frac{w}{p}\right)^{11-h} \). We see that it is split precisely when \( \text{disc}(w) = -1 \).

Case 2. Turning now to the case of infinite height let us recall the setup of [a19]. (As we do not want to assume that \( p = 22 \) we shall however replace \( NS \otimes \mathbb{Z}_p \) by the flat cohomology group \( H^2(X, \mathbb{Z}_p(1)) \), which it is equal to when \( p = 22 \)). We let \( N \) be the flat cohomology group \( H^2(X, \mathbb{Z}_p(1)) \) and consider \( N \otimes k \) with \( F \) acting as \( \text{id} \otimes F \). We then have de Rham Chern class map \( c_1: N \to H^2_{\text{dR}}(X/k) \) and we shall also \( c_1 \) for the \( k \)-linear extension \( N \otimes k \to H^2_{\text{dR}}(X/k) \) of \( c_1 \). The kernel of this map plays the central role. We write the kernel of it on the form \( F^*K \) for some sub-vector space \( K \subseteq N \otimes k \). We let \( \bar{K} \) be the inverse image of \( K \) in \( N \otimes W \). We can consider \( \mathcal{H} \) as a \( W \)-submodule of \( N \otimes Q \), where \( Q \) is the fraction field of \( W \). Then, by definition and the fact that \( pN^* \subseteq N \), with \( N^* \) the dual of \( N \) with respect to the intersection pairing, we have that \( \mathcal{H} = p^{-1}k^* \bar{K} \). Furthermore, as \( F = p \otimes \sigma \) on \( N \otimes W \) it is clear that

\[
\mathcal{H}_1 = F^{-1}p\mathcal{H} = p^{-1}(\bar{K} \cap k^* \bar{K}) \quad \text{and} \quad \mathcal{H}_0 = F^{-1}p^2K = \bar{K}
\]

and they map to the Hodge filtration of \( H \). On the other hand,

\[
\mathcal{H}_0^c = F(\mathcal{H}_2) = \sigma^*2(\bar{K}) \quad \text{and} \quad \mathcal{H}_1^c = p^{-1}F(\mathcal{H}_1) = p^{-1}(\sigma^* \bar{K} \cap \sigma^*2 \bar{K})
\]

which then map to the conjugate filtration. Starting our procedure for constructing the canonical filtration we see that it stops immediately when \( H_0 = H_0^c \), but this is the case precisely when the
Artin invariant \( \sigma_0 \) equals 1. If not, we add the image \( E_2 \) of \( H_0^\bullet \) in \( H/H_0 \) to the Hodge filtration, whose inverse image in \( H \) then is \( U_2 := \tilde{K} + \sigma^3 \tilde{K} + \sigma^2 \tilde{K} \). The next step is to transfer \( E_2 \) via the Cartier isomorphism to get an addition, \( V_2 \), to the conjugate filtration. As the Cartier isomorphism between the “middle parts” of the Hodge and conjugate filtrations is implemented by \( p^{-1} F = \sigma^* \) we get that the inverse image of \( V_2 \) in \( H \) is given by

\[
\sigma^* \tilde{K} + \sigma^2 \tilde{K} + \sigma \tilde{K}.
\]

The process stops at that stage precisely when \( \sigma^3 \tilde{K} \leq \tilde{K} + \sigma^3 \tilde{K} + \sigma^2 \tilde{K} \) which in turn is equivalent to \( \tilde{K} + \sigma^3 \tilde{K} + \sigma^2 \tilde{K} = pN^* \otimes W(k) \) (by [loc. cit. 3.12.3]) and thus to \( \sigma_0 = 2 \) (as we have put ourselves in the case when \( \sigma_0 > 1 \)). If not, the process continues, forcing us to add the image of \( \sigma^2 \tilde{K} + \sigma^3 \tilde{K} + \sigma^4 \tilde{K} \) to the Hodge filtration. If we continue in this way it is clear that we will stop at \( \tilde{K} + \sigma^3 \tilde{K} + \cdots + \sigma^m \tilde{K} \) which equals \( pN^* \otimes W(k) \). In this way we get an extension of the Hodge filtration which ends at \( R \otimes k \), where \( R \) is the radical of \( N := N \otimes \mathbb{F}_p \). Its annihilator is \( N \otimes k \) and hence we get that the “middle subquotient” of the canonical filtration is canonically isomorphic to \( N/R \otimes k \) with the natural quadratic structure and the map induced by the Cartier isomorphism having \( N/R \) as its fixed points. Hence extending the canonical filtration to a final one amounts to finding a complete self-dual flag in \( N/R \). We also get from [loc. cit. 3.4] and the fact that the discriminant of \( N(X) \) is \( -p^{2\sigma_0} \) that the quadratic form on \( N/R \) is non-split.

Also in this case it is evident by inspection from the filtration thus obtained that it is of type \( w_{n-1} \sigma_0 \) or \( w'_{n-1} \sigma_0 \) in the case where \( \sigma_0 = n/2 \) we find \( w_{n-1} \sigma_0 \). In the general case we see that the F-zip is the sum of an F-zip of dimension \( 2\sigma_0 \) and a Tate F-zip which is isomorphic to the middle part F-zip. From the multiplicativity of the Hodge discriminant and the case \( n = 2\sigma_0 \) we conclude.

8 Shuffles

In this section we shall discuss an analogue and generalization of shuffles introduced in [EG10]. They play a role in describing maps between the strata \( U_w \) on the flag space. They are a key instrument for deciding whether the push forward of the corresponding cycle class will vanish.

Lemma 8.1

i) Let \( w \) be an element of a Coxeter group and suppose that \( \ell(ws_i) = \ell(w) - 1 \). Then either \( \ell(s_iws_i) = \ell(w) \) or \( \ell(s_iws_i) = \ell(w) - 2 \).

ii) For \( w \) an element of \( W_m \), \( W_n \), or \( W_m \) and \( 1 \leq i < m \) we have that \( \ell(ws_i) = \ell(w) - 1 \) precisely when \( w(i + 1) < w(i) \) and then \( \ell(s_iws_i) = \ell(w) - 2 \) precisely when \( w^{-1}(i + 1) < w^{-1}(i) \).

iii) For \( w \) an element of \( W_m \) we have \( \ell(ws_m) = \ell(w) - 1 \) precisely when \( w(m) > w(m + 1) \) and then \( \ell(s_mws_m) = \ell(w) - 2 \) precisely when \( w^{-1}(m + 2) < m \).

iv) For \( w \) an element of \( W_n \) we have \( \ell(ws_m) = \ell(w) - 1 \) precisely when \( w(m + 1) > w(m + 2) \) and then \( \ell(s_mws_m) = \ell(w) - 2 \) precisely when \( w^{-1}(m + 1) < m \).

v) For \( w \in W_m \) we have \( \ell(ws_m) = \ell(w) - 1 \) precisely when \( w(m - 1) > w(m + 1) \) and \( w(m) > w(m + 2) \) and then \( \ell(s_mws_m) = \ell(w) - 2 \) precisely when \( w^{-1}(m + 1) > w^{-1}(m + 2) \).

Proof: Easy.

Assume now that \( w \in W_n \) and that \( \ell(ws_i) = \ell(w) - 1 \) for some \( 1 < i \leq m \). This means that for the universal flags \( E_i \) and \( G_i \) on \( U_w \) the image of \( G_{w(i+1)} \cap E_{i+1} \) in \( E_{i+1}/E_{i+1} \) is a line bundle. We define a new self-dual flag \( E'_i \) on \( U_w \) by the condition that \( E'_i = E_j \) for \( i \neq j \leq n \) and \( E'_i/E_{i-1} \) be equal to the image of \( G_{w(i+1)} \cap E_{i+1} \). This then gives a map

\[
\sigma_{w,i} \colon U_w \to \mathcal{F}_n, \quad (E'_i,G_i) \mapsto (E'_i,G_i)
\]

which we shall call the \( i \)'th elementary shuffle map for \( w \). We say that the shuffle map is unambiguous if there is a \( v \in W_n \) such that the image of \( \sigma_{w,i} \) lies in \( U_v \). Please note the condition \( i > 1 \) which ensures that the first and last step of the Hodge filtration are left unchanged.
Proposition 8.2  

i) The element $\sigma_{w,i}$ for $w \in W_n$ is unambiguous precisely when $\ell(s_i w s_i) = \ell(w)$. In that case the image of $\sigma_{w,i}$ is equal to $U_{s_i w s_i}$ and $\sigma_{w,i}$ is finite and purely inseparable of degree $p$.

ii) If $\ell(s_i w s_i) = \ell(w) - 2$ then $\sigma_{w,i}$ maps onto $U_{w s_i} \cup U_{s_i w s_i}$. In particular it is not generically finite.

Proof: Assume first that $\ell(s_i w s_i) = \ell(w)$. We may locally (in the étale topology) choose a basis adapted to the two flags, i.e., an orthonormal basis $e_1, \ldots, e_n$ of $M$ (on $U_w$) such that $E_j$ is spanned by $e_1, \ldots, e_j$ and $G_{w^{-1}(j)}$ is spanned by $e_{w^{-1}(1)}, \ldots, e_{w^{-1}(j)}$. We then have that $E_i'$ is spanned by $e_1, \ldots, e_i, e_{i+1}$. We may further assume that $C^{-1} e_j = e_{w^{-1}(j)} \mod G_{j-1}$ for all $1 < j < n$. Put $k := w^{-1}(i)$ and $\ell := w^{-1}(i + 1)$, we then have, by the assumption and Lemma [3], that $k < \ell$. There is a $\lambda$ such that $C^{-1} e_{i+1} = e_\ell + \lambda e_k \mod G_{i-1}$. We now put for $j \leq m$

$$e_j' = \begin{cases} e_j & \text{if } j \neq i, i + 1, \ell, \\ e_{i+1} & \text{if } j = i, \\ e_i & \text{if } j = i + 1, \\ e_\ell & \text{if } j = \ell. \end{cases}$$

By the assumption $k < \ell$ we get that $E_i'$ is spanned by $e_1', \ldots, e_j'$ and we may extend it (uniquely) to an adapted basis for $E_i'$ and $G_i'$. This makes it clear that $(E_i', G_i')$ is of type $s_i w s_i$.

Consider conversely the universal flag $E_i$ on $U_w$, where $w = s_i w s_i$ and put again $k := w^{-1}(i)$ and $\ell := w^{-1}(i + 1)$, where this time $k > \ell$ and $w^{-1}(i) < w^{-1}(i + 1)$.

We choose as before an adapted basis and let $E_i'$ be spanned by $e_1, \ldots, e_{i+1} + \rho e_i$ and then $G_i'$ is spanned by $e_\ell + (\rho^p + \lambda) e_k$ and $G_{i-1}$. It is then easy to see that $(E_i', G_i')$ is of type $w$ precisely when $\rho^p + \lambda = 0$ which gives i).

We now assume that $\ell(s_i w s_i) = \ell(w) - 2$. The setup is then the same as before except that we now have $k > \ell$. This means that $(E_i', G_i')$ will be of type $w s_i$ if $\lambda \neq 0$ and of type $s_i w s_i$ if $\lambda = 0$. The converse is similar to the converse of i) (with the difference that the new flag pair will be of type $w$ for all choices of $\rho$).

Definition 8.3  

A sequence of elements $w_1, \ldots, w_r$ of $W_n$ is said to be a shuffle sequence if for each $1 \leq k < r$ there is an $1 < i_k \leq m$ such that $\ell(w_k s_i_k) = \ell(w_k) - 1$ and $w_{k+1} = s_{i_k} w_k s_{i_k}$ with $\ell(s_{i_k} w_k s_{i_k}) = \ell(w_k)$. It is said to be ambiguous if there is an $i_k$ such that $\ell(w r s_{i_k}) = \ell(w r) - 1$ and $\ell(s_{i_k} w_k s_{i_k}) = \ell(w r) - 2$, final if $w_k$ is final, and cyclic if there are $1 \leq j < k < r$ such that $w_j = w_k$.

Proposition 8.4  

i) For every $w \in W_n$ there exists a shuffle sequence starting with $w$ and which is either ambiguous, final, or cyclic.

ii) If there is an ambiguous or cyclic shuffle sequence starting with $w \in W_n$, then the restriction of the projection map $F_n \to K_n$ to $U_w$ is not generically finite.

iii) Given a final shuffle sequence $w_1, \ldots, w_r$, the restriction of the projection map $F_n \to K_n$ to $U_{w_r}$ is the composite of a finite flat purely inseparable map of degree $p^{-1}$ and the finite étale map $U_{w_r} \to V_{w_r}$.

Proof: Let $w = w_1, \ldots, w_r$ be a shuffle sequence which is maximal for not being ambiguous, final, or cyclic. In particular $w_r$ is not final and therefore there is an $1 < i_r \leq m$ such that $\ell(w_r s_{i_r}) = \ell(w_r) - 1$. If $\ell(s_{i_r} w_r s_{i_r}) = \ell(w_r)$, then by the maximality we must have either that $w_{r+1} := s_{i_r} w_r s_{i_r}$ is final or appears in the sequence so that we get a final or cyclic sequence by adding $w_{r+1}$. If $\ell(s_{i_r} w_r s_{i_r}) = \ell(w_r) - 2$ we instead get an ambiguous sequence thus proving i).

If there is an ambiguous sequence $w = w_1, \ldots, w_r$, then the projection map $U_w$ factors by Proposition 8.2 as $U_w \to U_{w r s_{i_r}} \to U_{w r s_{i_r} w_r} \to K_n$ and as $\ell(w r s_{i_r}) < \ell(w)$ and $\ell(s_{i_r} w_r s_{i_r}) < \ell(w)$ and hence $U_w$ has an image of dimension smaller than that of $U_w$. On the other hand if there is a cyclic sequence, then the projection factors through an infinite sequence of $\sigma_{w, j}$’s and as each of them is of degree $> 1$ we get that image has lower dimension. This proves ii).
Finally, assume that we have a final sequence \( w = w_1, \ldots, w_r \). Then the projection factors as the composite \( \sigma_w \circ \cdots \circ \sigma_{w_r} \circ \sigma_{w_{r-1}} \circ \cdots \circ \sigma_{w_1} \cdot i_i \) and the projection \( U_{w, w_{r-1}, \ldots, w_1} \rightarrow K_n \). The latter is an étale cover of \( V_{w_1} \), and the first is finite purely inseparable of degree \( p \).

We shall call an ambiguous or cyclic shuffle a degenerate shuffle. Proposition \( \text{[5.4]} \) implies that either all shuffles of an element \( w \in \mathcal{W}_m \) are degenerate or they are all final. In the first case, the projection map restricted to \( \mathcal{U}_w \) is not generically finite on each of its irreducible components and in particular the image of \( [\mathcal{U}_w] \) is zero. In the second the class of the push forward is non-zero and equal \( p^\ell [\mathcal{U}_w] \), where \( \ell \) is the length of a final shuffle of \( w \) to the final element \( \nu \).

9 Final elements

9.1 Final elements in \( \mathcal{W}_m^B \)

In order to calculate cycle classes of our strata we shall apply a Pieri formula which gives an expression of the intersection product of a class of a stratum with a first Chern class in terms of cycle classes of strata of dimension one less. For this we need a precise description of the colength one elements in the Weyl group below a given final (or twisted final) element. In this auxiliary section we describe the elements involved.

We begin by factoring the final elements in the Weyl group \( \mathcal{W}_m^B \) as a product of simple reflections.

Lemma 9.1 The products \( \nu_k = s_ks_{k+1} \cdots s_{m}s_{m-1} \cdots s_1 \) with \( 1 \leq k \leq m-1 \) and \( \nu_{2m-k} = s_{k}s_{k-1} \cdots s_1 \) with \( m \geq k \geq 0 \) are reduced expressions for the \( 2m \) final elements of \( \mathcal{W}_m^B \). We have \( \nu_1 = \nu_0 \) and \( \nu_{2m} = 1 \).

Proof: Easily verified.

Note that the final elements are linearly ordered by their length. We now determine the elements of colength 1 below a final element in the Bruhat order.

Proposition 9.2 i) The elements in \( \mathcal{W}_m^B \) of colength 1 below the final element \( w = s_ks_{k+1} \cdots s_{m}s_{m-1} \cdots s_1 \) with \( k < m \) are \( s_k \cdots \hat{s}_i \cdots s_{m} \cdots s_1 \) for \( i = k, \ldots, m-1 \), and \( s_k \cdots \hat{s}_i \cdots s_{m} \cdots s_1 \) for \( i = m-1, m-2, \ldots, 1 \). They are obtained from the final element by multiplying \( w \) to the right by the element \( s_\alpha \), where \( \alpha \) is the root \( \epsilon_1 + \epsilon_{k+1}, \ldots, \epsilon_1 + \epsilon_m, \epsilon_1 - \epsilon_m, \ldots, \epsilon_1 - \epsilon_2 \) respectively.

ii) The elements of colength one below \( w = s_ks_{s_{k-1}} \cdots s_1 \) are the elements \( s_m \cdots \hat{s}_i \cdots s_1 \) for \( i = m, \ldots, 1 \). They are obtained by multiplying \( w \) from the right by \( s_\alpha \) where \( \alpha \) is the root \( \epsilon_1, \epsilon_1 - \epsilon_m, \epsilon_1 - \epsilon_{m-1}, \ldots, \epsilon_1 - \epsilon_2 \) respectively.

iii) The elements of colength one below \( w = s_k s_{k-1} \cdots s_1 \) are the elements \( s_k \cdots \hat{s}_i \cdots s_1 \) for \( i = k, \ldots, 1 \). They are obtained from the final element by multiplying \( w \) to the right by the element \( s_\alpha \), where \( \alpha \) is the root \( \epsilon_1 - \epsilon_{k+1}, \ldots, \epsilon_1 - \epsilon_2 \) respectively.

Proof: We know that the elements of colength 1 below an element are obtained by considering a reduced expression for the element, taking the elements obtained by removing one element from the expression, and then keeping the elements of colength 1. Lemma \( \text{[5.1]} \) provides a reduced expression. In case i), among the elements obtained by removing one simple reflection from the reduced expression clearly the one obtained by removing \( s_m \) (when present) is not of colength 1 and the others are easily shown to be. Finally, if the element has the factorization \( w'w'' \) and the colength 1 element has the factorization \( w'w'' \) then it is obtained by multiplying by \( (w'w'')^{-1}s_{m}s_{m-1} \) to the right, i.e., by \( s_\alpha \), where \( \alpha = (w'w'')^{-1}(\alpha_1) \). From this the rest follows by a simple calculation. The cases ii) and iii) are similar.

We shall now consider the elements of colength 1 below a final element and determine if they have degenerate or final shuffle type.

Proposition 9.3 i) The element \( s_ks_{k+1} \cdots s_{m} \cdots \hat{s}_i \cdots s_1 \) with \( 1 \leq i < k < m \) is degenerate.

ii) The element \( s_ks_{k+1} \cdots s_{m} \cdots \hat{s}_i \cdots s_1 \) with \( m > i \geq k \) has an elementary shuffle to the element \( s_ks_{k+1} \cdots s_{m} \cdots \hat{s}_{i+1} \cdots s_1 \) if \( i < m-1 \) and to \( s_ks_{k+1} \cdots \hat{s}_{m-1} \cdots s_1 \) if \( i = m-1 \).
iii) For $m > i > k$ the element $s_k \cdots \hat{s}_i \cdots s_m \cdots s_1$ has an elementary shuffle to the element $s_k \cdots \hat{s}_{i-1} \cdots s_m \cdots s_1$.

iv) The element $s_k \cdots \hat{s}_i \cdots s_1$ is degenerate if $i < k \leq m$.

**Proof:** Starting with i) we note that the elements $s_j$ with $k \leq j \leq i$ commute with the $s_i$ with $i-1 \geq l \geq 1$. This means that $s_k \cdots s_m \cdots s_{i-1} \cdots s_1 = s_k \cdots s_m \cdots s_{i+2s_{i-1}} \cdots s_{i+1}$ and this implies that we can perform an $i+1$st shuffle giving the element $s_{i+1}s_k \cdots s_m \cdots s_{i+2s_{i-1}} \cdots s_1$. If $i+1 = k$ this element has shorter length, while if $i+1 = k-1$ we get $s_{k-1} \cdots s_m \cdots s_{i+2s_{i-1}} \cdots s_1$ and then move $s_{i+2}$ to the right and perform a shuffle with it. We thus arrive at the element $s_{i+k-1}s_k \cdots s_m \cdots s_{i+3s_{i-1}} \cdots s_1$, and by applying the braid relation we get the element $s_{i+k-1}s_k \cdots s_m \cdots s_{i+3s_{i-1}} \cdots s_1$ and by moving $s_{k-1}$, the third factor, this is seen to equal $s_{k-1}s_k \cdots s_m \cdots s_{i+3s_{i-1}}s_{i-1} \cdots s_1$, and by moving $s_{i+1} = s_{k-1}$ to the right, then performing a shuffle by $s_{i+1}$ we get an element of shorter length. If, however, $i+1 < k-1$ we get $s_k \cdots s_m \cdots s_{i+3s_{i-1}}s_{i+2s_{i-1}} \cdots s_1$ and then we can perform a shuffle by $s_{i+2}$. Continuing in this way this leads to a shorter element.

We continue with ii) and assume that $i+1 \neq m$. Then $s_k s_{k+1} \cdots s_m \cdots s_{i+1} \cdots s_1$ equals $s_k s_{k+1} \cdots s_m \cdots s_{i+2} \cdots s_1$ as the involved simple transpositions commute. This means that we may perform an elementary shuffle to get the element $s_{i+1} s_k s_{k+1} \cdots s_m \cdots s_{i+2} \cdots s_1$ which in turn is equal to $s_k s_{k+1} \cdots s_{i+1} s_{i+2} \cdots s_1$. Using the braid rule we get that this element equals $s_k s_{k+1} \cdots s_{i+1} s_{i+2} \cdots s_1$, and we observe that this in turn equals $s_k s_{k+1} \cdots s_{i+1} s_{i+2} s_{i-1} \cdots s_1$ and this is $s_k \cdots s_m s_{i+1} \cdots s_1$. By Lemma 9.3 this element is reduced so that we have performed an unambiguous shuffle to the claimed element. If instead $i+1 = m$ we have that $s_k s_{k+1} \cdots s_m s_{m-2} \cdots s_1$ is equal to $s_k s_{k+1} \cdots s_m s_{m-2} \cdots s_1$ which on which its turn equals the element $s_k s_{k+1} \cdots s_{m-2} s_m s_{m-1} \cdots s_1$, a reduced expression of the right element.

For iii) note that $s_k s_{i-1} s_{i+1} \cdots s_m \cdots s_1$ equals $s_k \cdots s_{i-1} s_{i+1} \cdots s_m \cdots s_{i-1} s_{i-1} \cdots s_1$, and we observe that in the last $s_i$ migrates to the right to give $s_k \cdots s_{i+1} \cdots s_m \cdots s_{i-1} \cdots s_1$. Performing an elementary shuffle leads to $s_k s_{k+1} \cdots s_{i+1} \cdots s_m s_{i-1} \cdots s_1$ which is equal to the element $s_k s_{i+1} \cdots s_m s_{i-1} \cdots s_1$. This is, still by the lemma, a reduced expression of the desired element.

The proof of iv) is analogous to that of i).

**Corollary 9.4** i) For a final element $w = s_k \cdots s_m \cdots s_1$ with $k < m$ the only non-degenerate elements of colength 1 below $w$ are $w s_\alpha$ with $\alpha = \epsilon_1 + \epsilon_{k+1}, \ldots, \epsilon_1 + \epsilon_m, \epsilon_1 - \epsilon_m, \ldots, \epsilon_1 - \epsilon_{k+1}$.

ii) For the final element $w = s_m s_{m-1} \cdots s_1$ there is only one non-degenerate element of colength 1 below it, namely $w s_{\epsilon_1}$.

iii) For the final element $w = s_k \cdots s_1$ with $1 \leq k \leq m-1$ there is only one non-degenerate element of colength 1 below $w$, namely $w s_{\epsilon_1 - \epsilon_{k+1}}$.

### 9.2 Final elements in $W^D_m$

This section is analogous to the preceding one and we will therefore be brief.

**Lemma 9.5** The products $w_k = s_k \cdots s_{m-2m}s_{m-1} \cdots s_1$ with $1 \leq k \leq m-2$ together with the product $w_{m-1} = s_m s_{m-1} \cdots s_1$, the elements $w_m = s_m s_{m-2} \cdots s_1$ and $w_{m+1} = s_m \cdots s_{2m-2} \cdots s_1$ and the products $w_{m+j} = s_m s_{m-j-1} \cdots s_1$ with $j = 2, \ldots, m$ are reduced expressions for the $2m$ final elements of $W_m$. We have $w_1 = w_0$ and $w_{2m} = 1$.

**Proof:** Easily verified.

For each integer $\ell$ with $0 \leq \ell \leq 2m - 2$ and $\ell \neq m - 1$ there is one final element with length $\ell(w) = \ell$ while there are two final elements of length $m - 1$. We can associate a graph to these $2m$ final elements by associating a vertex to each final element and an edge to a pair $u, v$ if $v = s_j u$. 

for some $s_j$. Conjugation by $s'_m$ interchanges the two final elements of length $m - 1$.

![Diagram](image)

The colength 1 elements below the final elements are given in the following lemma.

**Lemma 9.6** i) There are $2m - k - 1$ elements in $W^D_m$ of colength 1 below the final element $w = s_k \cdots s_{m-2}s_m \cdots s_1$ for $k \leq m - 2$ and they are $s_k \cdots \hat{s}_i \cdots s_{m-2}s_m \cdots s_1 = ws_{i+\epsilon+1}$ for $i = k, \ldots, m - 2$, the elements $s_k \cdots s_{m-2}s_m s_{m-1} \cdots s_1 = ws_{\epsilon_1+\epsilon_m}$, $s_k \cdots s_{m-2}s_m s_{m-1} \cdots s_1 = ws_{s_{\epsilon_1-s_{\epsilon_m}}}$, and the elements $s_k \cdots s_{m-2}s_m s_{m-1} \cdots s_1 = ws_{\epsilon_{m+1-i}}$ for $i = 2, \ldots, m - 1$.

ii) There are $m$ elements of colength 1 below the final element $w = s_m s_{m-1} \cdots s_1$ and they are $ws_{\alpha}$ with $\alpha = \epsilon_1 + \epsilon_m, \epsilon_1 - \epsilon_m, (-\epsilon_1 - \epsilon_2).

iii) The elements in $W^D_m$ of colength 1 below the final element $w = s_m s_{m-2} \cdots s_1$ are $s_m s_{m-2} \cdots s_1 = ws_{s_{\epsilon_1-\epsilon_m}}$ and $s_m s_{m-2} \cdots s_1 = ws_{s_{\epsilon_1-\epsilon_m}}$ for $i = m - 2, \ldots, 1$.

iv) The elements in $W^D_m$ of colength 1 below the final element $w = s_{m-1} s_{m-2} \cdots s_1$ are $s_{m-1} s_{m-2} \cdots s_1 = ws_{s_{\epsilon_1-\epsilon_m}}$ and $s_{m-1} s_{m-2} \cdots s_1 = ws_{s_{\epsilon_1-\epsilon_m}}$ for $i = m - 2, \ldots, 1$.

v) The elements in $W^D_m$ of colength 1 below the final element $w = s_k \cdots s_1$ with $1 \leq k \leq m$ are the elements $s_k \cdots \hat{s}_i \cdots s_1 = ws_{s_{\epsilon_1-\epsilon_{k+1}}}$ for $i = k, \ldots, 1$.

**Proof:** The proof is analogous to the case of $W^B_m$ treated in the preceding section.

Again, we now consider the elements of colength 1 below a final element and determine if they have degenerate or final shuffle type.

**Proposition 9.7** i) The element $s_k \cdots s_{m-2}s_m \cdots \hat{s}_i \cdots s_1$ with $i < k \leq m - 2$ is degenerate.

ii) The element $s_k \cdots s_m s_{m-2} \cdots \hat{s}_i \cdots s_1$ with $i \geq k$ has an elementary shuffle by $(s_{i+1})$ to the element $s_k \cdots s_{m-2} \cdots \hat{s}_{i+1} \cdots s_1$ if $i < m - 2$ and a double shuffle (by $s_{m-1}s_m$) to $s_k \cdots s_{m-2} \cdots s_1$ if $i = m - 2$ and $k < m - 2$ and an elementary shuffle (by $s_m$) to $s_m \cdots s_1$ if $k = m - 2 = i$.

iii) The elements $s_k \cdots s_{m-2}s_m \cdots s_1$ and $s_k \cdots s_{m-2}s_m s_{m-1} \cdots s_1$ are degenerate.

iv) For $m - 2 \geq i \geq k$ the element $s_k \cdots \hat{s}_i \cdots s_{m-2}s_m \cdots s_1$ has an elementary shuffle (by $s_i$) to the element $s_k \cdots s_{i-1} \cdots s_{m-2}s_m \cdots s_1$.

v) The element $s_m \cdots \hat{s}_i \cdots s_1$ is degenerate if $m - 1 \leq i \leq 1$.

vi) The element $s_m s_{m-2} \cdots \hat{s}_i \cdots s_1$ with $m - 2 \geq i > 1$ is degenerate.

**Proof:** The proof is analogous to the $W^B_m$ case and is omitted.

**Corollary 9.8** i) For a final element $w = s_k \cdots s_{m-2}s_m \cdots s_1$ with $k \leq m - 2$ the only non-degenerate elements of colength 1 below $w$ are $ws_{\alpha}$ with $\alpha = \epsilon_1 + \epsilon_k, \ldots, \epsilon_1 + \epsilon_{m-1}, \epsilon_1 - \epsilon_{k+1}$.

ii) For the final element $s_m s_{m-1} \cdots s_1$ there are two non-degenerate elements of colength 1 below it, namely $ws_{s_{\epsilon_1+\epsilon_m}}$ and $ws_{s_{\epsilon_1-\epsilon_m}}$.

iii) For the final element $w = s_m s_{m-2} \cdots s_1$ there is only one non-degenerate element of colength 1 below it, namely $ws_{s_{\epsilon_1+\epsilon_m}}$.

iv) For the final element $w = s_{m-1} s_{m-2} \cdots s_1$ there is only one non-degenerate element of colength 1 below it, namely $ws_{s_{\epsilon_1-\epsilon_m}}$.

v) For the final element $w = s_k \cdots s_1$ with $1 \leq k \leq m - 2$ there is only one non-degenerate element of colength 1 below it, namely $ws_{s_{\epsilon_1-\epsilon_{k+1}}}$. 
9.3 Twisted final elements in $W^{D_m}$

The twisted final elements are of the form $ws'_m$ with $w$ as in Lemma 9.3. Similarly, the elements of colength 1 below a twisted final element $ws'_m$ are of the form $ws'_m$ with $u$ a colength 1 element below $w$ as described in Lemma 9.6. We have to analyze whether these elements are degenerate or have final shuffle type. We omit the analogue of Proposition 9.7 and formulate immediately the analogue of Corollary 9.8.

**Corollary 9.9**

(i) For a twisted final element $ws'_m$ with $w = s_k \ldots s_{m-2}s_{m} \ldots s_1$ and $k \leq m - 2$ the only non-degenerate elements of colength 1 below $ws'_m$ are of the form $us'_m$ with $u$ equal to $ws_n$ with $\alpha = \epsilon_1 + \epsilon_{k+1}, \ldots, \epsilon_1 + \epsilon_m$, and $\epsilon_1 - \epsilon_m, \ldots, \epsilon_1 - \epsilon_{k+1}$.

(ii) For the twisted final element $ws'_m$ with $w = s_ms_{m-1} \ldots s_1$ there are two non-degenerate elements of colength 1 below it, namely corresponding to $ws_{s_1+\epsilon_m}$ and $ws_{s_1-\epsilon_m}$.

(iii) For the twisted final element $ws'_m$ with $w = s_ms_{m-2} \ldots s_1$ there is only one non-degenerate element of colength 1 below it, namely corresponding to $ws_{s_1+\epsilon_m}$.

(iv) For the final element $ws'_m$ with $w = s_{m-1}s_{m-2} \ldots s_1$ there is only one non-degenerate element of colength 1 below it, namely corresponding to $ws_{s_1-\epsilon_m}$.

(v) For the final element $ws'_m$ with $w = s_k \ldots s_1$ with $1 \leq k \leq m - 2$ there is only one non-degenerate element of colength 1 below it, namely corresponding to $ws_{s_1-\epsilon_{k+1}}$.

10 The local structure of strata

The reason for working on the flag space over our moduli space is that the strata are much better behaved than on the moduli space. In fact, up to infinitesimal order $< p$ the strata look like usual Schubert strata. This idea of [FG10] and the methods employed there can be transferred to our situation. Hence we assume that we have a family $f : X \to S$ of $N$-marked K3-surfaces (where $S$ may be an algebraic stack). We shall also need to assume a versality condition: For any geometric point $s$ of $S$ contraction of forms by vector fields induces a map $H^1(X_s, T_{X_s}) \to \text{Hom}(H^0(X_s, \Omega^2_{X_s}), H^1(X_s, \Omega^1_{X_s}))$ we can then compose this with the map induced by the projection on the second factor of the decomposition $H^1(X_s, \Omega^1_{X_s}) = N \otimes k \perp P$ and then further compose the resulting map with the Kodaira-Spencer map $T_sS \to H^1(X_s, T_{X_s})$. The required versality condition is that $S$ be smooth at all $s$ and that the composed map $T_sS \to \text{Hom}(H^0(X_s, \Omega^2_{X_s}), P)$ be surjective.

The space $F_n$ together with the $U_n$ is a stratified space. The space $F_{1,n}$ of complete self-dual flags on an orthogonal space is also a stratified space with the stratification given by the Schubert cells. The idea is that our flag space at a point can be identified up to the $(p - 1)$st neighborhood with the flag space at an appropriate point. Moreover, under this correspondence the strata on $F_n$ correspond precisely to the Schubert strata on $F_{1,n}$. This enables us to transplant the detailed knowledge about Schubert strata up to order $p$ to our situation. More precisely, if $R$ is a local ring with maximal ideal $m$ defining an affine scheme $S$ then the height-1 hull of $R$ (or $S$) is given by $R/m^{(p)}$, with $m^{(p)}$ generated by the $p$th powers of elements of $m$. We call two local rings are height 1-isomorphic if their respective height 1-hulls are isomorphic.

**Theorem 10.1** Let $k$ be a perfect field $k$ of positive characteristic $p$. For each $k$-point $x$ of $F_n$ there is a $k$-point $y$ of $F_{1,n}$ such that the height 1-neighbourhood of $x$ is isomorphic to the height 1-neighbourhood of $y$ times a smooth space by a stratified isomorphism.

**Proof:** We consider the de-Rham cohomology $H$ together with the Gauss-Manin connection on the height-1 neighborhood $Y$ of $x$. We can trivialize $H$ plus its Gauss-Manin connection on $Y$ since the ideal of $x$ has a divided power structure for which divided powers of degree $\geq$ are zero. This implies that the orthogonal flags $E_x$ and $G_x$ on $H$ are horizontal. We thus get a map from $Y$ to the space of orthogonal flags on a standard orthogonal space, that is, an isomorphism from $Y$ to a height-1 neighborhood on $F_{1,n}$. It is not difficult to see that it preserves strata. □

The following theorem is the main consequence of this.
Theorem 10.2  i) Each stratum $U_w$ is smooth of dimension $\ell(w)$.
  
  ii) The closed stratum $\overline{U}_w$ is reduced, Cohen-Macaulay and normal of dimension $\ell(w)$ and is the closure of $U_w$ for all $w$ in the Weyl group.
  
  iii) If $w$ is final then the restriction of the projection $F_n \to K_n$ is a finite surjective étale covering from $U_w$ to $V_w$ of degree equal to the number of final filtrations on a canonical filtration of type $w$.

Proof: This theorem follows from Thm 10.1 in exactly the same fashion as Corollary 8.4 in Section 8.2 of [EG1] follows from Theorem 8.1 there.

Lemma 10.3 Let $w \in W^B_m$ be a final element and let $\pi_w : U_w \to V_w$ be the restriction of the projection from $F_n \to K_n$ with $n = 2m + 1$.

i) For $1 \leq k \leq m - 1$ we have $\deg(\pi_{w_k})/\deg(\pi_{w_{k+1}}) = p^{2m - 2k - 1} + p^{2m - 2k - 2} + \ldots + 1$.

ii) Similarly, we have $\deg(\pi_{w_{m+k}})/\deg(\pi_{w_{m+k+1}}) = p^{2k-1} + p^{2k-2} + \ldots + 1$.

Proof: Note that $\deg(\pi_w)$ is the number of final filtrations on a given canonical filtration of type $w$. For case i) we look at the number of lines in a linear space of dimension $2m - 2k$ over $\mathbf{F}_p$, i.e. the number of points in projective space of dimension $2m - 2k$. For case ii) we look at the number of isotropic lines in an orthogonal space of dimension $2k + 1$, i.e. the degree is the number of points on a quadric of dimension $2k - 1$.

Lemma 10.4 Let $w \in W^D_m$ be a final element and let $\pi_w : U_w \to V_w$ be the restriction of the projection from $F_n \to K_n$ with $n = 2m$.

i) For $1 \leq k \leq m - 1$ we have $\deg(\pi_{w_k})/\deg(\pi_{w_{k+1}}) = p^{m-k-1} + \sum_{j=0}^{2m-2k-2} p^j$.

ii) We have $\deg(\pi_{w_{m-1}}) = \deg(\pi_{w_m}) = (\pi_{w_{m+1}}) = (\pi_{w_{m+2}}) = 1$.

iii) Similarly, for $2 \leq k \leq m - 1$ we have $\deg(\pi_{w_{m+k}})/\deg(\pi_{w_{m+k+1}}) = p^{k-1} + \sum_{j=0}^{2k-2} p^j$.

Proof: The proof is the same as for Lemma 10.3 except that the count of isotropic lines are different. It also depends on whether the form is split or not but that is provided by Theorem 7.1.

Lemma 10.5 Let $w = w's' \in W^D_m$ be a twisted final element and let $\pi_w : U_w \to V_w$ be the restriction of the projection from $F_n \to K_n$ with $n = 2m$.

i) For $1 \leq k \leq m - 1$ we have $\deg(\pi_{w_k})/\deg(\pi_{w_{k+1}}) = p^{m-k-1} + \sum_{j=0}^{2m-2k-2} p^j$.

ii) We have $\deg(\pi_{w_{m-1}}) = \deg(\pi_{w_m}) = (\pi_{w_{m+1}}) = (\pi_{w_{m+2}}) = 1$.

iii) Similarly, for $2 \leq k \leq m - 1$ we have $\deg(\pi_{w_{m+k}})/\deg(\pi_{w_{m+k+1}}) = -p^{k-1} + \sum_{j=0}^{2k-2} p^j$.

Proof: Again the proof is the same as for Lemma 10.3 with needed extra information provided by Theorem 7.1.

11 Pieri’s formula and the cycle classes of the strata

Since the strata in our case, unlike the abelian case, are (almost) linearly ordered we can fruitfully apply a Pieri type formula to get a formula for the classes of $\overline{V}_\nu$. The appropriate formula is the Pieri formula of Pittie and Ram ([PR9]). There is a small problem in that the result only applies when we start with a $G$-torsor over a connected semi-simple group $G$ and in our case the structure group is the disconnected group $O(n)$. The resolution of this problem differs somewhat in the two cases of even or odd $n$ so part of the discussion is postponed to the separate discussions for the two cases. In any case, the Pittie-Ram formula expresses the intersection product of the cycle class of a stratum with a first Chern class in terms of cycle classes of strata of one dimension less. We have to use the formula on the flag space and then project it down. The precise details of the Pieri formula differ enough between the odd and even dimensional cases to make separate discussions in the two cases. Throughout we shall assume the versality assumption made in the preceding section.
11.1 The odd-dimensional case

We now assume \( n = 2m + 1 \). Now, \( O(2m+1) = SO(2m+1) \times \{ \pm 1 \} \) and hence an \( O(2m+1) \)-torsor is the same thing as one \( SO(2m+1) \)-torsor and one double cover. Thus the problem mentioned above is resolved by considering instead the \( SO(2m+1) \)-torsor. In concrete terms this means replacing our \( F \)-zip vector bundle \( H \) by \( H \otimes \det(H) \).

We want to apply the Pieri formula to the two complete flags that we have on the flag space \( F_n \). If we let \( \lambda = \sum n_i \ell_i \), where \( \ell_i = c_1(E_i/E_{i-1}) \) for \( 1 \leq i \leq m \) is the first Chern class corresponding to the root \( \epsilon_i \). The starting point for the Pieri formula is the following construction: Given a sequence \( z = (z_1, \ldots, z_m) \) of cohomology classes (of fixed degree) and a weight vector \( \lambda = \sum n_i \ell_i \) (in the weight lattice of type \( B_m \)) we define \( z^\lambda := \sum n_i z_i \). We shall apply this to \( x = (\ell_1, \ldots, \ell_m) \) and \( y = (k_1, \ldots, k_m) \), where \( k_i := c_1(G_i/G_{i-1}) \) and then, for suitable \( \lambda \), we shall consider \( x^\lambda \) and \( y^\lambda \). However, the elements of \( x \) and \( y \) span the same subgroup of the cohomology so we can also write \( y^\lambda \) as \( x^{\lambda'} \) for a suitable \( \lambda' \). Clearly the association \( \lambda \to \lambda' \) is a linear operator on the weight lattice. It is easily seen that just as for the symplectic case it is given by \( \lambda' = pw_\emptyset w(\lambda) \). From this point on we shall only be considering elements of the form \( x^\mu \) and for simplicity we shall write them just as \( \mu \). The Pieri formula (see the proof of [EG10, Thm 10.1] for details) now takes the form

\[
(1 - pw_\emptyset w)(\lambda)[\mathcal{U}_w] = - \sum_{\ell(w_{s_n}) = \ell(w)-1} \langle \alpha, \lambda \rangle [\mathcal{U}_w^{w_{s_n}}].
\]

The term \( 1 - pw_\emptyset w \) is viewed as an element of the group ring \( \mathbb{Q}[\mathcal{W}_m^B] \) acting on the roots \( \ell_i \) and the sum is over roots \( \alpha \) such that the length \( \ell(w_{s_n}) \) is one less than the length of \( w \). Moreover, \( \alpha \) is the usual coroot defined by \( \alpha \).

To obtain a formula for the multiplication of \( [\mathcal{U}_w] \) by a given line bundle \( \rho \) we have to solve the equation \( (1 - pw_\emptyset w)(\lambda) = \rho \). If we put \( v := w_\emptyset w \) and if we let \( c \) be the smallest positive integer such that \( v^c(\rho) = s\rho \) for some \( s \in \{ \pm 1 \} \) then a solution is given by

\[
\lambda = \frac{1}{1 - sp^c} \sum_{i=0}^{c-1} p^i v^i(\rho).
\]

We carry this out with \( \rho = \ell_1 = \lambda_1 \), the first Chern class of the Hodge bundle, such that we obtain a formula for \( \lambda_1[\mathcal{U}_w] \). We shall call \( c \) the reduced orbit length and say that the orbit is even or odd according to as \( s \) is \( +1 \) or \( -1 \). Then we push down to the moduli space. The degenerate strata push down to zero and the non-degenerate to a power of \( p \) times the push down of a final stratum.

The final elements in this case are of the form \( w_k = s_1 \cdots s_m \cdots s_1 \) with \( 1 \leq k < m \) and \( w_{k+m} = s_m \cdots s_m \cdots s_1 \cdots s_1 \) for \( 0 \leq k \leq m-1 \) and \( w_{2m} = 1 \). Note that \( w_\emptyset = w_1 \) with this usage. The corresponding final strata on the flag space are \( \mathcal{U}_{w_k} \) with \( k = 1, \ldots, 2m \) with corresponding strata \( \nabla_{w_k} \) on the moduli space. For a final element we denote the canonical map \( \mathcal{U}_w \to \nabla_w \) by \( \pi_w \) and its degree by \( \deg(\pi_w) \).

**Remark:** The strata \( \nabla_{w_k} \) for \( 1 \leq k \leq m \) are the strata corresponding to finite height equal to \( k \), the stratum \( \nabla_{w_{m+1}} \) is the supersingular stratum and the stratum \( \nabla_{w_{k+m}} \) corresponds to Artin invariant equal to \( m+1-k \) for \( 1 \leq k \leq m \).

**Theorem 11.1** The cycle classes of the final strata \( \nabla_w \) on the base \( S \) are polynomials in \( \lambda_1 \) with coefficients that are polynomials in \( \frac{1}{2} \mathbb{Z}[p] \) given by

1. \( [\nabla_{w_k}] = (p-1)(p^2-1) \cdots (p^{k-1}-1)\lambda_1^{k-1} \) if \( 1 \leq k \leq m \),
2. \( [\nabla_{w_{m+1}}] = \frac{1}{2}(p-1)(p^2-1) \cdots (p^{m-1}-1)\lambda_1^m \),
3. \( [\nabla_{w_{m+k}}] = \frac{1}{2}(p^{2k} - 1)(p^{2(k+1)} - 1) \cdots (p^{2m} - 1) \lambda_1^{m+k-1} \) if \( 2 \leq k \leq m \).
PROOF: We start with a final element $w$ of the form $w_k = s_k \cdots s_m \cdots s_1$ with $1 \leq k < m$. The colength 1 elements $w_k s_\alpha$ that are not degenerate correspond to the $2m - 2k$ elements $\alpha_1 = \epsilon_1 + \epsilon_{k+1}, \ldots, \alpha_{m-k} = \epsilon_1 + \epsilon_m, \alpha_{m-k+1} = \epsilon_1 - \epsilon_m, \ldots, \alpha_{2m-2k} = \epsilon_1 - \epsilon_{k+1}$. These are the only elements that will contribute to the push down. Note that we have $w_k s_{\alpha_1} = w_{k+1}$, again a final element.

For the element $v = w_0 w$ we have $v^j(1) = 2m + 1 - k + j$ for $j = 1, \ldots, k - 1$ which means that the reduced orbit length is $k$ and the orbit even. We thus find that

$$(1 - pv)\lambda_1 = \sum_{i=0}^{k-1} p^i v^j(\ell_1) = \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i}.$$ 

Therefore the Pieri formula gives

$$(p^k - 1)\lambda_1 [\mathcal{U}_{w_k}] = \sum_{j=1}^{m-1} (\epsilon_1 + \epsilon_{k+j}, \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i}) [\mathcal{U}_{w_k^{s_{\alpha_j}}}] + \sum_{j=1}^{m-1} (\epsilon_1 - \epsilon_{m+1-j}, \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i}) [\mathcal{U}_{w_k^{s_{\alpha_{m-k+j}}}}],$$

where $\equiv$ means that we count modulo degenerate strata. Pushing it down annihilates the classes of the degenerate strata and yields

$$(p^k - 1)\lambda_1 [\mathcal{V}_{w_k}] \deg(\pi_{w_k}) = \sum_{j=1}^{2m-2k} [\mathcal{V}_{w_k^{s_{\alpha_j}}} \deg(\pi_{w_k^{s_{\alpha_j}}}) = (1 + p + \ldots + p^{2m-2k-1}) [\mathcal{V}_{w_{k+1}}] \deg(\pi_{w_{k+1}})$$

since the $w_k s_{\alpha_j}$ for $j = 2, \ldots, 2m - 2k$ are shuffles of $w_{k+1} = w s_{\alpha_1}$ which map to $\mathcal{V}_{w_{k+1}}$ with degree $p^j - 1$. By Lemma 10.3 we have $\deg(\pi_{w_k})/\deg(\pi_{w_k^{s_{\alpha_j}}}) = p^{2m-2k-1} + \ldots + 1$ and get $[\mathcal{V}_{w_{k+1}}] = (p^k - 1)[\mathcal{V}_{w_k}]$ for $k = 1, \ldots, m - 1$. Since $[\mathcal{V}_{w_1}] = 1$ part i) follows.

For part ii) we note that there is only one non-degenerate element of colength 1, namely $w s_{\alpha} = w_{m+1}$ and it corresponds to $\alpha = \epsilon_1$ with $\alpha = 2 \epsilon_1$. Note that $v = [m + 2, 2m + 1, 2, 3, \ldots, m - 1]$ and $\sum_{i=0}^{m-1} p^i v^j(\ell_1) = \ell_1 - \sum_{i=1}^{m-1} p^i \ell_{m+1-i}$. This gives

$$(p^m - 1)[\mathcal{V}_{w_m}] \deg(\pi_{w_m}) = 2 [\mathcal{V}_{w_{m+1}}] \deg(\pi_{w_{m+1}})$$

and we observe that $\deg(\pi_{w_m}) = 1 = \deg(\pi_{w_{m+1}})$. This proves ii).

For the case iii) we consider a final element $w_{k+m} = s_{m-k} s_{m-k-1} \cdots s_1$ with $k \geq 1$. There is only one non-degenerate element $w_{k+m} s_\alpha$ of colength 1, namely $w_{k+1+m}$ with $\alpha = \epsilon_1 - \epsilon_{m+1-k}$.

The element $v = w_0 w_{m+k} = [m, 2m + 1, 2, 3, \ldots]$ has an odd orbit of reduced orbit length $m + 1 - k$ and thus $v^{m+1-k} \lambda_1 = -\lambda_1$ so that $\sum_{i=0}^{m-k} p^i v^j(\ell_1) = \ell_1 + \sum_{i=1}^{m-k} p^i \ell_{m+2-k-i}$ and the Pieri formula gives

$$(p^{m-k} - 1)\lambda_1 [\mathcal{M}_{m+k}] \deg(\pi_{w_{m+k}}) = (p - 1)[\mathcal{V}_{w_{m+k+1}}] \deg(\pi_{w_{m+k+1}}).$$

Here we have $\deg(\pi_{w_{m+k+1}})/\deg(\pi_{w_{m+k}}) = p^{2k-1} + \ldots + 1$ which gives $(p^{m-k} + 1)\lambda_1 [\mathcal{M}_{m+k}] = (p^{2k-1} - 1)[\mathcal{V}_{w_{m+k+1}}]$. This proves the formulas.

That the formulas are up to a factor $1/2$ polynomials in $\mathbb{Z}[\lambda_1, p]$ is clear for cases i) and ii) and follows from next remark for case iii).

Remark: The formula for case iii) can also be written as

$$[\mathcal{V}_{w_{m+k}}] = \frac{1}{2} \prod_{j=1}^{m+1-k} (p^j - 1) \left[ \frac{m}{m + 1 - k} \right] \lambda_1^{m+k-1},$$

where $[n, i)_q$ is the usual $q$-binomial coefficient.
11.2 The even-dimensional case

The reduction to an SO-torsor in the even case is more involved than in the odd case. To begin with if we have an O(2m)-torsor $P \rightarrow X$ we get a double cover $Y := P/\text{SO}(2m) \rightarrow X$ and the quotient map $P \rightarrow Y$ is an SO(2m)-torsor. However, in order to have a Bruhat cell decomposition of $P \rightarrow Y$ (which is necessary even to formulate the Pieri formula) we need a reduction of the structure group to $B$ (a Borel subgroup of SO(2m)). This we get from our original setup in the following way: We can find a subgroup $B' \subset \text{O}(2m)$ containing $B$ as a subgroup of index 2 and we assume that we have a $B'$-torsor $Q \rightarrow X$ which then gives rise to a $B$-torsor $Q \rightarrow Q/B = Y$. If we look at the corresponding $G/B$-fibrations (where $G = \text{SO}(2m)$) we get a commutative diagram

$$Q \times_B G/B \longrightarrow Q \times_{B'} G/B$$

$$\downarrow \hspace{1cm} \downarrow$$

$$Y \longrightarrow X$$

and we get a Pieri formula to $Q \times_B G/B \rightarrow Y$ and then push it down to $Q \times_{B'} G/B$. What happens during this pushdown is the following: The class $\lambda_1$ (which is the only class for which we shall use the Pieri formula) is the pullback of a class on $Q \times_{B'} G/B$ so by the projection formula it can be moved out of the push down. We get a “Bruhat decomposition” also of $Q \times_{B'} G/B$ but the strata now corresponds to $B'$-orbits of $G/B$. Such an orbit is a union of one or two $B$-orbits depending on whether or not an element in $B' \setminus B$ fixes the $B$-orbit or not. Hence, the projection $Q \times_B G/B \rightarrow Q \times_{B'} G/B$ maps Bruhat strata to Bruhat strata and two strata $\mathcal{U}_w$ and $\mathcal{U}'_w$ in $Q \times_B G/B$ are mapped to the same stratum precisely when either $w'' = w$ or $w'' = s_m w s_m'$. In our specific case the $B'$-bundle arises by starting with a $G'$-torsor ($G' = \text{O}(2m)$) $P \rightarrow X$ and then pulling it back along $P \times_{G'/B'} G'/B'$ (note that $G'/B' = G/B$ where this pullback has a canonical reduction of its structure group to $B'$.

In flag terms we have the following description. Let $E$ be a quadratic vector bundle of rank $2m$ over $X$. The pairing on it induces an isomorphism $\text{det}(E) \otimes \text{det}(E) \cong O_X$ and hence gives a double cover $Y \rightarrow X$. We can also consider the *almost complete* flag space $\mathcal{F} \rightarrow X$ of self dual flags $0 \subset E_1 \subset E_2 \subset \cdots \subset E_{m-1} \subset E_{m+1} \subset E_{2m} = E$ with dim $E_i = i$. The fibre product $\mathcal{F}' := X \times_\mathcal{F} F$ has the explicit description as the space of complete self dual flags $0 \subset E_1 \subset E_2 \subset \cdots \subset E_{m-1} \subset E_m \subset E_{m+1} \subset \cdots \subset E_{2m} = E$ and the double cover involution on $Y$ induces the operation on such flags which replaces $E_m$ by the other totally isotropic $m$-dimensional subspace $E_{m-1} \subset E'_m \subset E_{m+1}$. The fibre product $\mathcal{F}'' := \mathcal{F}' \times_\mathcal{F} \mathcal{F}'$ consisting of pairs $(E_*, F_*)$ of complete self dual flags split up in two components: one is $\mathcal{F}'_0$, where $\dim(E_m \cap F_m) \equiv m \mod 2$, and the other one is $\mathcal{F}'_1$, where $\dim(E_m \cap F_m) \equiv m + 1 \mod 2$. The group $\mathbb{Z}/2 \times \mathbb{Z}/2$ acts on $\mathcal{F}' \times_\mathcal{F} \mathcal{F}'$, a group factor acting on the corresponding factor of $\mathcal{F}' \times_\mathcal{F} \mathcal{F}'$. The elements $(1, 0)$ and $(0, 1)$ permutes the two components and $(1, 1)$ preserves them. Each element $w \in W_m^D$ gives a stratum of $\mathcal{F}''$ consisting of the flags in relative position $w$. When $w \in W_m^D$, the stratum lies in $\mathcal{F}''_1$ and when $w \in W_m^D s_m^j$ it lies in $\mathcal{F}''_j$. The group element $(1, 0)$ then takes the stratum of $w$ to that of $s_m w$ and the element $(0, 1)$ takes $w$ to that of $s_m^j w$.

11.2.1 The untwisted even case

The first step in getting to a Pieri formula is to identify the linear map that takes $\lambda$ to $\lambda'$. This time it is *not* given by $pw\theta w$ as $w\theta(m) = m + 1$ which does not have the desired effect. Instead we have to use the linear map $pw\theta w$ because $w\theta(m) = m$. This means that Pieri’s formula takes the form

$$(1 - pw\theta w)(\lambda)[\mathcal{U}_w] = - \sum_{\ell(s_m) = \ell(w) - 1} \langle \alpha, \lambda \rangle [\mathcal{U}_w s_m]$$

Recall that the final elements are the $2m$ elements $w_k = s_k \cdots s_m s_{m-2} \cdots s_1$ for $k = 1, \ldots, m - 2$, $w_{m-1} = s_m s_{m-1} \cdots s_1$, $w_m = s_m s_{m-2} \cdots s_1$ and $w_{m+j} = s_{m-j} \cdots s_1$ for $j = 1, \ldots, m - 1$ and
Theorem 11.2 The cycle classes of the final strata $\nabla_w$ for final $w_j \in W_m^D$ on the base $S$ are powers of $\lambda_1$ times polynomials in $\frac{1}{k}\mathbb{Z}[p]$ given by

i) $[\nabla_{w_k}] = (p - 1)(p^2 - 1) \cdots (p^{k-1} - 1)\lambda_1^{k-1}$ if $k \leq m - 1$,

ii) $[\nabla_{w_{m+1}}] = (p - 1)(p^2 - 1) \cdots (p^{m-1} - 1)\lambda_1^{m-1}$,

iii) $[\nabla_{w_{m+k}}] = \frac{1}{2} \prod_{j=1}^{m-k} (p^j - 1) \prod_{i=1}^{m-k+2} (p^i + 1) \prod_{i=1}^{m-k-1} (p^i - 1)\lambda_1^{m+k-2}$ if $2 \leq k \leq m$.

Furthermore, we have that $\nabla_{w_m} = \emptyset$.

Proof: Let $w_k = s_k \cdots s_{m-2}s_m \cdots s_1$ be a final element with $1 \leq k \leq m - 2$. There are $2m - 2k - 2$ non-degenerate elements of colength 1 under $w_k$ and they are of the form $w_{a_i}$ with $a_i = \epsilon_1 + \epsilon_{k+1}, \ldots, \alpha_{m-k} = \epsilon_1 + \epsilon_{m-1}$ and $\alpha_{m-k} = \epsilon_1 - \epsilon_{m-1}, \ldots, \alpha_{2m-2k-2} = \epsilon_1 - \epsilon_{k+1}$. We find that $v := w'_0w_k$ has an even orbit of reduced orbit length $k$ and

$$(1 - pv)\lambda_1 = \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i}.$$}

Therefore the Pieri formula gives

$$(p^k - 1)\lambda_1[\nabla_{w_k}] \equiv \sum_{j=1}^{m-k-1} (\epsilon_1 + \epsilon_{k+j}, \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i})[\nabla_{w_{a_j}}] + \sum_{j=m-k}^{2m-2k-2} (\epsilon_1 - \epsilon_{2m-k+1-j}, \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i})[\nabla_{w_{a_j}}],$$

where $\equiv$ means again that we work modulo degenerate strata. Pushing it down annihilates the classes of the degenerate strata and yields

$$(p^k - 1)\lambda_1[\nabla_{w_k}] \text{deg}(\pi_{w_k}) = \sum_{j=0}^{2m-2k-2} \text{deg}(\pi_{w_{a_j}}) + (1 + \ldots + p^{m-k-2} + p^{m-k} + \ldots + p^{2m-2k-2})[\nabla_{w_{k+1}}] \text{deg}(\pi_{w_{k+1}}),$$

since the $w_{k,a_j}$ for $j = 1, \ldots, m - k - 1$ are shuffles of $w_{k+1} = w_{a_0}$ for which $U_{w_{k,a_j}}$ maps to $U_{w_{k+1}}$ with degree $p^{j-1}$, while for $j = m - k, \ldots, 2m - 2k - 2$ we get degree $p^j$. By Lemma 10.3 we have $\text{deg}(\pi_{w_k})/\text{deg}(\pi_{w_{k+1}}) = p^{2m-2k-2} + \ldots + p^{m-k} + p^{m-k-2} + \ldots + 1$ and hence get

$$(p^k - 1)\lambda_1[\nabla_{w_k}] = (p^j - 1)\lambda_1[\nabla_{w_j}]$$

for $k = 1, \ldots, m - 1$. Since $[\nabla_{w_1}] = 1$ part i) follows.

For part ii) we consider the final element $w = s_m s_{m-1} \ldots s_1$ and see that $v := w'_0w$ has an even orbit of reduced orbit length $m - 1$ and that $(1 - pv)\lambda_1 = \ell_1 - \sum_{i=1}^{m-2} p^i \ell_{m-1-i}$. In this case there are two non-degenerate elements of colength 1 namely $w_{a_0}$ with $a$ being equal to $\epsilon_1 + \epsilon_m$ and $\epsilon_1 - \epsilon_m$ respectively. Applying the Pieri formula and pushing down first to the unoriented flag space and then to the moduli space we get

$$(p^{m-1} - 1)\lambda_1[\nabla_{w_{m-1}}] \text{deg}(\pi_{w_{m-1}}) = [\nabla_{w_m + w_{m+1}}] \text{deg}(\pi_{w_m}).$$

By Lemma 10.3 $\text{deg}(\pi_{w_{m-1}}) = \text{deg}(\pi_{w_m}) = 1$ which gives ii) after pushing down.

For part iii) we consider the element $w_m = s_m s_{m-2} \ldots s_1$. The element $v := w'_0w$ has an odd orbit of reduced orbit length $m$ and we have

$$(1 - pv)\lambda_1 = \ell_1 - p^m \ell_m + \sum_{i=2}^{m-1} p^i \ell_{m+1-i}.$$
There is now only one non-degenerate element of colength 1, namely $w_m s_\alpha$ with $\alpha = \epsilon_1 + \epsilon_m$. We get
\[(p^m + 1)\lambda_1 (\nabla_{w_m + w_m - 1}) \text{deg}(\pi_{w_m}) = (p - 1) (\nabla_{w_m + 2}) \text{deg}(\pi_{w_m + 2})\].

Again by Lemma 10.4 we have $\text{deg}(\pi_{w_m}) = \text{deg}(\pi_{w_m + 2}) = 1$.

Now take $w = w_{m+j} = s_{m-j} \ldots s_1$ with $j \geq 2$. The element $v := w'_j w$ has an odd orbit of reduced orbit length $m - j$. We get
\[(1 - pv) \lambda_1 = \epsilon_1 + \sum_{i=1}^{m-j} p^i \epsilon_{m+2-j-i} \].

There is again only one non-degenerate element of colength 1, namely $w_m s_\alpha$ with $\alpha = \epsilon_1 - \epsilon_{m+1-j}$. Therefore $(\alpha, \lambda) = (1 - p^{j-1})$. We find
\[(p^{m+1-j} + 1)\lambda_1 (\nabla_{w_{m+j}}) \text{deg}(\pi_{w_{m+j}}) = (p^{j-1} - 1) (\nabla_{w_{m+j}}) \text{deg}(\pi_{w_{m+j+1}})\].

By Lemma 10.4 we have $\text{deg}(\pi_{w_{m+j+1}}) = p^{2j-2} + \ldots + 2p^{j-1} + \ldots + 1$. Using the factorization $p^{2j-2} + \ldots + 2p^{j-1} + \ldots + 1 = (p^{j-1} + 1)(p^{j-1} + p^{j-2} + \ldots + 1) = (1 + p^{j-1})/(1 - p^j)$ and iterating we get the formula. As there is only a small number of cases, the fact that one gets polynomials is most easily verified by explicit computation (one could also use [EG10, Prop. 13.2]).

**Remark:** Similarly to the odd case we can write the third formula as
\[
\frac{p^{k-1} + 1}{p^m - 1} \prod_{i=1}^{m+1-k} (p^j - 1) \begin{pmatrix} m \\ k - 1 \end{pmatrix}_{p^2},
\]
though this does not make it visibly a polynomial in $p$.

**11.2.2 The twisted even case**

We now turn to the twisted even-dimensional case. Going back to the previous notation we have the space $F''$ of pairs of complete flags of $H$ where $H$ now is the de Rham cohomology of the universal K3-surface. We have a disjoint decomposition $F'' = F''_0 \cup F''_1$, where $F''_0$ is the $G/B$-fibration over $F'$ with structure group $B$ and where we consequently have a Pieri formula. However, the $F$-zip structure on $H$ gives a section of the projection (on the first factor) $F'' \to F'$ which is contained completely in $F''_0$. In order to get a section along which we can pullback a Pieri formula on $F''_0$ we must compose with the isomorphism $F''_1 \to F''_0$ obtained by applying the involution of $F''$ acting on the second factor (say) of $F''$. This extra involution implies that the linear map $\lambda \mapsto \lambda'$ is now given by $pu_\mathbb{Z}w$ (and not by $pu_\mathbb{Z}w'$ as in the untwisted case). Apart from that the argument of the Pieri formula proceeds along lines very similar to the untwisted case.

Recall that the final elements are $2m$ elements $w_k = s_k \ldots s_{m-2} s_{m-1} s_1$ for $k = 1, \ldots, m - 2$, $w_{m-1} = s_m s_{m-1} \ldots s_1$, $w_m = s_m s_{m-2} \ldots s_1$ and $w_{m+j} = s_{m-j} \ldots s_1$ for $j = 1, \ldots, m - 1$ and $w_{2m} = 1$.

**Theorem 11.3** The cycle classes of the final strata $\nabla_w$ for twisted final elements $w_j \in W_{m,s_j}'$ on the base $S$ are powers in $\lambda_1$ with coefficients that are polynomials in $\frac{1}{2} \mathbb{Z}[p]$ given by

\begin{itemize}
  \item[i)] $[\nabla_{w_j}] = (p - 1)(p^2 - 1) \cdots (p^{k-1} - 1) \lambda_1^{k-1}$ if $k \leq m - 1$,
  \item[ii)] $[\nabla_{w_m}] = (p - 1)(p^2 - 1) \cdots (p^m - 1) \lambda_1^{m-1}$,
  \item[iii)] $[\nabla_{w_{m+k}}] = \frac{1}{2} \prod_{i=1}^{m-1} (p^j - 1) \prod_{i=m-k+2}^{m-1} (p^j + 1) \lambda_1^{m+k-2}$ if $2 \leq k \leq m$.
\end{itemize}
Furthermore, we have $\overline{\nabla}_{w_{m+1}} = \emptyset$.

**Proof:** Let $w_k = s_k \ldots s_m t_{s_m} \ldots s_1$ be a final element with $1 \leq k \leq m - 2$. There are $2m - 2k$ non-degenerate elements of colength 1 under $w_k$ and they are of the form $ws_\alpha$ with $\alpha_1 = \epsilon_1 + \epsilon_{k+1}, \ldots, \alpha_{m-k} = \epsilon_1 + \epsilon_m$ and $\alpha_{m-k+1} = \epsilon_1 - \epsilon_m, \ldots, \alpha_{2m-2k} = \epsilon_1 - \epsilon_{k+1}$. We find that $v := w_k w_k$ has an even orbit of reduced orbit length $k$ and

$$(1 - pv)\lambda_1 = \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i}$$

Therefore the Pieri formula gives

$$(p^k - 1)\lambda_1 [\overline{\nabla}_{w_k}] \equiv \sum_{j=0}^{m-k} (\epsilon_1 + \epsilon_{k+j}, \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i})[\overline{\nabla}_{ws_\alpha_j}] + \sum_{j=m-k+1}^{2m-2k} (\epsilon_1 - \epsilon_{2m-k+1-j}, \ell_1 - \sum_{i=1}^{k-1} p^i \ell_{k+1-i})[\overline{\nabla}_{w_{s_\alpha_j-1}}],$$

where $\equiv$ means again that we work modulo degenerate strata. Pushing it down annihilates the classes of the degenerate strata and yields

$$(p^k - 1)\lambda_1 [\overline{\nabla}_{w_k}] \deg(\pi_{w_k}) = \sum_{j=1}^{2m-2k} [\overline{\nabla}_{w_{k+1}}] \deg(\pi_{ws_\alpha_j}) = (1 + \ldots + 2p^{m-k-1} + \ldots + 2p^{2m-2k-2})[\overline{\nabla}_{w_{k+1}}] \deg(\pi_{w_{k+1}}),$$

since the $w_k s_{\alpha_j}$ for $j = 1, \ldots, m - k$ are shuffles of $w_{k+1} = w s_{\alpha_{k+1}}$ for which $\overline{\nabla}_{w_k s_\alpha}$ maps to $\overline{\nabla}_{w_{k+1}}$ with degree $p^j$, while for $j = m - k + 1, \ldots, 2m - 2k$ we get degree $p^{j-2}$. By Lemma 10.4 we have $\deg(\pi_{w_k}) / \deg(\pi_{w_{k+1}}) = p^{2m-2k-2} + \ldots + 2p^{m-k-1} + \ldots + 1$ and hence get $[\overline{\nabla}_{w_{k+1}}] = (p^k - 1)[\overline{\nabla}_{w_k}]$ for $k = 1, \ldots, m - 1$. Since $[\overline{\nabla}_{w_1}] = 1$ part i) follows.

For part ii) we consider the final element $w = s_m s_{m-1} \ldots s_1$ and see that $v := w_k w$ has an even orbit of reduced orbit length $m - 1$ and that $(1 - pv)\lambda_1 = \ell_1 - \sum_{i=1}^{m-2} p^i \ell_{m-i}$. In this case there are two non-degenerate elements of colength 1 namely $ws_\alpha$ with $\alpha_1 = \epsilon_1 + \epsilon_m$ and $\alpha_2 = \epsilon_1 - \epsilon_m$. Applying the formula we get

$$(p^{m-1} - 1)\lambda_1 [\overline{\nabla}_{w_m-1}] \deg(\pi_{w_{m-1}}) = [\overline{\nabla}_{w_{s_\alpha_1}}] \deg(\pi_{w_m}) + [\overline{\nabla}_{w_{s_\alpha_2}}] \deg(\pi_{w_{m+1}}).$$

By Lemma 10.3 $\deg(\pi_{w_{m-1}}) = \deg(\pi_{w_m}) = 1$ which gives ii) after pushing down.

For part iii) we consider the element $w_m = s_m s_{m-2} \ldots s_1$. The element $v := w_k w$ has an even orbit of reduced orbit length $m$ and we have

$$(1 - pv)\lambda_1 = \ell_1 + p \ell_m - \sum_{i=2}^{m-1} p^i \ell_{m+1-i}.$$
There is again only one non-degenerate element $w_s$ with $\alpha = \epsilon_1 - \epsilon_{m+1-j}$. Therefore $\langle \alpha, \lambda \rangle = (1 - p^{j-1})$. We find

$$(p^{m+1-j} + 1)\lambda_1 [\nabla_{w_{m+j}}] \deg(\pi_{w_{m+j}}) = (p^{j-1} - 1) [\nabla_{w_{m+j}}] \deg(\pi_{w_{m+j}+1}).$$

By Lemma 10.4 we have $\deg(\pi_{w_{m+j}}) = p^{2j-2} + \cdots + p^j + p^{j-2} + \cdots + 1$. Using the factorization $p^{2j-2} + \cdots + p^j + p^{j-2} + \cdots + 1 = (p^j + 1)(p^{j-2} + p^{j-2} + \cdots + 1)$ and iterating we get the formula. Again the polynomiality is most easily verified by explicit computation. □

**Remark:** This time formula iii) can be rewritten

$$\frac{1}{2} \frac{p^{k-1} - 1}{p^m + 1} \prod_{i=1}^{m-k+1} (p^i - 1) \left[ \frac{m}{k-1} \right]_{p^2}.$$  

**Remark:** It is not unreasonable to conjecture that the $\nabla_{w_k}$ are complete for $k \geq 3$. Moreover, the class $\lambda_1$ is conjectured to be ample on the moduli space. In characteristic 0 this follows from Baily-Borel. If this is true then the open strata $\nabla_{w_k}$ for $k \geq 3$ are affine.

## 12 Applications

We shall now discuss two applications both pertaining to the even case.

### 12.1 (Quasi-)Elliptic fibrations with a section

If $X$ is a K3-surface and $f: X \to \mathbb{P}^1$ is an elliptic (or possibly quasi-elliptic in characteristic 3) fibration with a section $E \subset X$ a section, then $E$ and a general fibre $F$ span a hyperbolic plane $H$ in $\text{NS}(X)$ thus giving a $H$-marking of $X$. Let now $\mathcal{M}^{es}$ be the stack of K3-surfaces together with a (quasi-)elliptic fibration (with base $\mathbb{P}^1$) with a chosen section on it. As the choice of an ample line bundle is not part of the choices made let us take a moment to explain why this is an algebraic stack. We can consider the stack of K3-like (i.e., a surface with rational double points only as singularities and whose minimal resolution is a K3-surface) with an (quasi-)elliptic fibration with a section and irreducible fibres which is smooth along the section. Three times a fibre plus the section is an ample divisor and hence the stack of such surfaces is algebraic. Then $\mathcal{M}^{es}$ is the Artin-Brieskorn simultaneous resolution stack of it.

**Proposition 12.1** $\mathcal{M}^{es}$ is of twisted even type of rank 20 so that Theorem 11.3 applies with $m = 10$. In particular $\sigma_0 = 10$ is not possible.

**Proof:** We start by verifying the versality hypothesis for $\mathcal{M}^{es}$. Let us therefore fix a geometric point $X \to \text{Spec} \, k$. Recall that deformations of K3-surfaces are unobstructed and the derivative of the period map $H^1(X, T_X) \to \text{Hom}(H^0(X, \Omega^2_X), H^1(X, \Omega^1_X))$ is an isomorphism. Consider now the closed (formal) subscheme $A$ of some formal universal deformation $X \to S$ of $X$ defined by the condition that the $H$-marking of extend over $A$. Then $A$ is defined by two equations and its tangent space, as a subspace of $H^1(X, T_X)$ is given by the condition that $v \cdot c_1(\mathcal{L}) = 0 \in H^2(X, \mathcal{O}_X)$ for all line bundles $\mathcal{L} \in H$ and where $c_1(\mathcal{L}) \in H^1(X, \Omega^1_X)$ is the Hodge cohomology Chern class (induced by dlog: $\mathcal{O}^1_X \to \Omega^1_X$). As the degree of the polarization is prime to $p$, $c_1$ gives an injection $H \otimes k \hookrightarrow H^1(X, \Omega^1_X)$ and hence the codimension of $T_s(A)$ in $T_s(S)$, where $s$ is the closed point of $S$, is 2 and hence $A$ is smooth. Furthermore, it also follows that $T_0(A)$ maps isomorphically onto $\text{Hom}(H^0(X, \Omega^2_X), P)$, where $P$ is the primitive part of $H^1(X, \Omega^1_X)$. This gives the required versality for the stack of $H$-marked surfaces. What remains to show is that if the marking of $X$ comes from a (quasi-)elliptic fibration with a section then so does any deformation of it. For the fibration we let $\mathcal{L} = \mathcal{O}_X(F)$ be the line bundle of a fibre $F$. Then $H^1(X, \mathcal{L}) = 0$ and hence for any extension of it (to some closed subscheme of $S$), its direct
image will be a vector bundle \( \mathcal{E} \) of rank 2 which gives a map to the \( \mathbb{P}(\mathcal{E}) \)-bundle extending the (quasi-)elliptic fibration. Similarly, the section is a \((-2)\)-curve \( E \) and as \( H^1(X, \mathcal{O}_X(E)) = 0 \) any extension of \( \mathcal{O}_X(E) \) will give an extension of the curve which then is a section. By construction both line bundles extend over \( A \).

As the discriminant of \( \mathbb{H} \) is \(-1\) we get by Theorem 7.1 that the Hodge discriminant of the primitive part is equal to 1. Then from Proposition 5.2 (and the fact that in the notations of that proposition \( m = 10 \)) we conclude that we are in the twisted case. Theorem 11.3 then gives the classes of the height and Artin invariant strata (together with the fact that \( \sigma_0 = 10 \) is not possible).

**Remark**: There is an alternative way of excluding \( \sigma_0 = 10 \) similar to the way Artin excluded \( \sigma_0 = 11 \) for a general supersingular K3-surface. By [ASD73] a supersingular (quasi-)elliptic K3-surface \( X \) has \( \rho = 22 \) and by the fact that \( \mathbb{H} \) is unimodular we get that \( \text{NS}(X) = \mathbb{H} \perp P \). If \( \sigma_0(X) = 10 \), then the scalar product on \( P \) is divisible by \( p \) and \( P(1/p) \) is a unimodular even negative definite form of rank 20 which is not possible as its index, 20, is not divisible by 8. This argument has the advantage of working also for \( p = 2 \).

### 12.2 Proof of Theorem A

In order to prove Theorem A of the introduction we need to verify the versality condition as the theorem then follows from Theorem 11.1. However the proof of the versality is completely standard and essential the same as the proof in the previous case of elliptic surfaces with a section.

### 12.3 The canonical double cover of an Enriques surface

We let \( N \) be the lattice \( E_{10}(-1) = \mathbb{H} \perp E_8(-1) \) and we fix a chamber (inside of the positive cone) with respect to the roots of \( N \) (see [CD89, II§5] for a discussion of chambers in \( E_{10}(-1) \)). Let \( \mathcal{M}^E \) be the moduli stack of marked Enriques surfaces where a marking is an isometry between the standard Enriques lattice \( N_{10} = \mathbb{H} \perp E_8(-1) \) and the Néron-Severi group taking the fixed chamber into the ample cone of the Néron-Severi group. We can then construct \( \mathcal{M}^{E,d} \rightarrow \mathcal{M}^E \), the moduli stack of canonical double covers of marked Enriques surfaces (i.e., while \( \mathcal{M}^E(S) \), for a scheme \( S \), is the groupoid of families of marked Enriques surfaces over \( S \), \( \mathcal{M}^{E,d}(S) \) is the groupoid of families of marked Enriques surfaces together with an unramified double cover of the Enriques surface which is fibrewise non-trivial).

**Remark**: Note that \( \mathcal{M}^{E,d} \rightarrow \mathcal{M}^E \) is not an isomorphism but rather a (non-trivial) \( \mathbb{Z}/2 \)-gerbe. The non-triviality is reflected in the fact that given a family \( X \rightarrow S \) of Enriques surfaces a canonical double cover \( X' \rightarrow X \) which is non-trivial over every geometric fibre over \( S \). There is an obstruction in \( H^2(S, \mathbb{Z}/2) \) which in general is non-zero to the existence of such a cover, making “canonical double cover” something of a misnomer.

Pulling back the Néron-Severi group along the universal double cover \( X' \rightarrow X \) over \( \mathcal{M}^{E,d} \) we get a marking by \( N(2) \) of the family \( X' \rightarrow \mathcal{M}^{E,d} \) of K3-surfaces.

**Proposition 12.2** \( \mathcal{M}^{E,d} \) is of twisted even type of rank 12 so that Theorem 11.3 applies with \( m = 6 \). In particular \( \sigma_0 = 6 \) is not possible.

**Proof**: Again we start by verifying that \( \mathcal{M}^{E,d} \) fulfils the versality condition. We use the fact that \( \mathcal{M}^{E,d} \) also can be described as the stack of K3-surfaces together with \( \iota \), a fixed point free involution. Its tangent space is then the space of linear maps \( H^0(X, \Omega^1_X) \rightarrow H^1(X, \Omega_X) \) commuting with the involution. Now, \( \iota \) acts by \(-1\) on \( H^0(X, \Omega^1_X) \) and by \(+1\) on \( N(2) \otimes \mathbb{k} \) and \(-1\) on \( P \) under the decomposition \( H^1(X, \Omega_X) = N(2) \otimes \mathbb{k} \perp P \) which gives what we want.

The marking has discriminant \(-2^{10}\) which is \(-1\) up to squares just as in the previous example. Hence we are in the twisted even case (with \( m = 6 \)) and again Theorem 11.3 applies.
Remark: Also in this case there is an arithmetic proof of the impossibility of $\sigma_0 = 6$. The proof does not extend to characteristic 2 however as the polarization is not of degree prime to 2 (and the situation is in fact quite different in characteristic 2).
