Abstract

We present several ideas in the direction of physical interpretation of $q$- and $f$-oscillators as nonlinear oscillators. First we show that an arbitrary one-dimensional integrable system in action-angle variables can be naturally represented as a classical and quantum $f$-oscillator. As an example, the semi-relativistic oscillator as a descriptive of the Landau levels for relativistic electron in magnetic field is solved as an $f$-oscillator. By using dispersion relation for $q$-oscillator we solve the linear $q$-Schrödinger equation and corresponding nonlinear complex $q$-Burgers equation. The same dispersion allows us to construct integrable $q$-NLS model as a deformation of cubic NLS in terms of recursion operator of NLS hierarchy. A peculiar property of the model is to be completely integrable at any order of expansion in deformation parameter around $q = 1$.

As another variation on the theme, we consider hydrodynamic flow in bounded domain. For the flow bounded by two concentric circles we formulate the two circle theorem and construct the solution as the $q$-periodic flow by non-symmetric $q$-calculus. Then we generalize this theorem to the flow in the wedge domain bounded by two arcs. This two circular-wedge theorem determines images of the flow by extension of $q$-calculus to two bases: the real one, corresponding to circular arcs and the complex one, with $q$ as a primitive root of unity. As an application, the vortex motion in annular domain as a nonlinear oscillator in the form of classical and quantum $f$-oscillator is studied. Extending idea of $q$-oscillator to two bases with the golden ratio, we describe Fibonacci numbers as a special type of $q$-numbers with matrix Binet formula. We derive the corresponding golden quantum oscillator, nonlinear coherent states and Fock–Bargman representation. Its spectrum satisfies the triple relations, while the energy levels’ relative difference approaches asymptotically to the golden ratio and has no classical limit.

Keywords: $q$-oscillator, NLS hierarchy, nonlinear oscillator, circle theorem, Fibonacci numbers

1. Introduction

The harmonic oscillator has played a central role in classical and modern science, starting from the elementary pendulum in the seventeenth century, when the ideas of Johannes Kepler signified an important intermediate step between the previous magic-symbolical and the modern quantitative-mathematical description of nature [1]. At that time, the birth of classical physics was caused by application of an abstract idea of periodicity to a concrete variety of problems [2]. Wave theory and Fourier series are some tools developed from this concept in classical physics. But only in modern science have we observed an essentially new qualitative transition from dynamics to the oscillation theory. It was emphasized by Mandelstam in lectures on oscillation theory [3] that the difference between standard dynamics and the oscillation theory is that in dynamics we are interested in a description of what is going on in a given place at a given time, while in the oscillation theory we are interested in the motion of the system as a whole. In the classical mechanical picture of the world, positions and velocities are primary objects, while oscillations are the secondary ones. However, starting from quantum mechanics, in which our knowledge of simultaneous positions and velocities is restricted by the Heisenberg uncertainty relations, this point of view has been drastically changed. Wave mechanics affirms that the wholeness of the quantum process is something of the same primacy as position of a particle. And every particle is associated with some stationary oscillation process. It is essential to note that knowledge of phase of the particle and knowledge of the stationary state are excluding from each other. The phase of the particle (trajectory) in a single stationary state does not exist, since any attempt to derive this phase switches the system to another stationary state [4]. This way the basic
characteristic of oscillation theory, as a consideration of the process as a whole, comes to underlie the fundamental questions of mechanics in the quantum world. This point of view also influenced the modern theory of nonlinear dynamical systems, studying the qualitative behavior of a system in the phase space, its integrability properties and chaos [5].

In a recent development of quantum integrable systems, the concept of a quantum group as a deformation of the Lie group with deformation parameter $q$ was discovered. The notion of quantum $q$-oscillator as a $q$-deformed harmonic oscillator was introduced in studies on the quantum Heisenberg–Weyl group [6–8]. This oscillator is related to so-called symmetric $q$-calculus [11], while another version of $q$-oscillator [9, 10] is related to non-symmetric $q$-calculus. The difference is in definition of $q$-number and several generalizations of these numbers and oscillators with different bases were found. In the large stream of articles devoted to $q$-oscillator, here we would like to emphasize the set of papers published by Man’ko and co-authors [12–14].

In these papers the physical approach to $q$-oscillator as a nonlinear oscillator was developed. It was shown that it is an oscillator with frequency depending on its energy in the form of hyperbolic cosine function of the energy. The classical motion of this nonlinear oscillator becomes descriptive of the motion of a $q$-oscillator and the frequency of oscillations is increasing exponentially with energy. By standard quantization of this nonlinear system, the authors got a quantum $q$-oscillator as a nonlinear quantum oscillator with anharmonicity described by power series in energy. Then they generalized the approach to an arbitrary energy dependence of frequency and called it as the $f$-oscillator. In fact, in addition to frequency, any constant parameters in some exactly solvable system can be replaced by integrals of motion. This idea in some sense continues Dirac’s approach to fundamental constants as a simple functions slowly varying in time. The slow variation of parameters can be implemented by adiabatic invariants and integrals of motion, with corresponding quantization. Then starting from any integrable system one can replace parameters of the system by integrals of motion and get the hierarchy of integrable systems from the given one.

In the present paper we develop several ideas as a variations on such approach to $q$- and $f$-oscillators as the main theme. In section 2 we show that an arbitrary one-dimensional integrable model in action-angle variables has natural description as a classical and quantum $f$-oscillator. As an example we consider a semi-relativistic oscillator, related with Landau levels for relativistic electron in magnetic field. In section 3 we review some results on symmetric $q$-oscillator and in the next section 4 we study linear $q$-Schrödinger equation with dispersion relation of this oscillator. The symmetry operators and polynomial solutions with moving zeros are described, as well as nonlinearization of the model by complex Cole–Hopf-Madelung transformation. The symmetry of the linear equation then is rewritten as Bäcklund transformation for the nonlinear $q$-Burgers equation. In section 6, following the general procedure developed in [28], we construct the nonlinear Schrödinger equation with symmetric $q$-dispersion. This $q$-NLS equation is an integrable model from NLS hierarchy with Lax representation, infinite number of integrals of motion, soliton solutions etc. In the limit $q \rightarrow 1$ it reduces to NLS, which is one of the universal soliton equations and for $q \approx 1$ provides higher order corrections in dispersion and nonlinearity. A peculiar property of the model is to be completely integrable at any order of expansion in deformation parameter around $q = 1$. As a next variation on $q$-calculus application in section 7 we consider hydrodynamic flow in bounded circular wedge domain. We formulate general two circular wedge theorem and show that the flow is determined by $q$-periodic functions. For real $q = r_q^2/r_1^2$ it is the flow in annular concentric circles domain, while for wedge with angle $\pi/n$, $q$ is the primitive root of unity. For a vortex problem in such domains we describe a full set of vortex images as a kaleidoscope in terms of $q$-elementary functions. As an application we describe the point vortex motion in annular domain as a nonlinear oscillator with frequency depending on radius of motion. Then we find the $f$-oscillator form of this model and discuss corresponding quantization. Finally, in section 10 by introducing the matrix form of Binet formula for Fibonacci numbers, we solve the so-called golden oscillator and find corresponding coherent states and Fock–Bargman type representation. Details of some proofs are given in the appendix.

We regret that in this paper we are not able to give a complete list of references in this very wide field of research. Instead of this we try to represent some basic ideas in a pedagogical way.

2. Integrable models and nonlinear oscillators

Representation of an integrable model by the action-angle variables allows one to interpret the model as a set of nonlinear oscillators. For simplicity here we illustrate the idea only for the one degree of freedom Hamiltonian system. Due to conservation of energy this system is integrable. Let $H(p, q)$ be the Hamiltonian function with canonical variables $(q, p)$. The action and angle variables $(J, \theta)$ are introduced by generating function, [15]

$$S(q, J) = S(q, H(J)) = \int^q p(q, H)\,dq,$$

(1)

as the abbreviated action, in the following way

$$J = \frac{1}{2\pi} \oint p(q, H)\,dq = J(H), \quad \theta = \frac{\partial S(q, J)}{\partial J}.$$

(2)

We suppose that the motion is finite and the integral is taken along the full period of oscillations. Hamilton’s equations of motion in these variables are

$$J = -\frac{\partial H(J)}{\partial \theta} = 0, \quad \theta = \frac{\partial H(J)}{\partial J} \equiv \omega(J).$$

(3)

The first equation implies that $H$ is a function of $J$ only, independent of $\theta$ (cyclic coordinate), and the action variable, as well as the energy $E$ is an integral of motion. The second
equation determines nonlinear frequency \( \omega = \omega(J) \) and solution

\[
J = J(E), \quad \theta(t) = \omega(J)t + \theta_0.
\]

The change of \( S \) and \( \theta \) in the period is

\[
\Delta S = \oint p\,dq = 2\pi J, \quad \Delta \theta = \frac{\partial \Delta S}{\partial J} = 2\pi,
\]

and trajectory of the system represents a curve on the cylindrical surface in phase space \((p, q)\) endowed with time axis \( t \) [15]. Then, original variable \((q, p)\) as functions of \((J, \theta)\) are periodic and can be decomposed to Fourier series as the spectral decomposition

\[
q(J, \theta) = \sum_{n=-\infty}^{\infty} q_n(J)e^{in\theta}, \quad p(J, \theta) = \sum_{n=-\infty}^{\infty} p_n(J)e^{in\theta}.
\]

2.1.1. Linear oscillator. As an example, the linear oscillator

\[
H_0 = \frac{p^2}{2m} + \frac{m\omega_0^2 q^2}{2}
\]

in action variables is

\[
H_0(J) = \omega_0 J, \quad \omega(J) = \omega_0
\]

with the following solution

\[
J = \frac{H_0}{\omega_0}, \quad \theta(t) = \omega_0 t + \theta_0.
\]

The spectral decomposition has only harmonics with \( n = \pm 1 \) and

\[
q(J, \theta) = \sqrt{\frac{2J}{m\omega_0}} \sin(\omega_0 t + \theta_0), \quad p(J, \theta) = \sqrt{2Jm\omega_0} \cos(\omega_0 t + \theta_0).\]

Appearance of other modes in the decomposition (6) means anharmonicity in oscillations.

2.1.2. Complex coordinates. Quantization of action-angle variables implies that the action variable \( J \) is replaced by Hermitian operator \( J \), while instead of \( \theta \) one should use the unitary operator \( e^{i\theta} \) [4, 16]. This suggests that proper variables for quantization of the system in action-angle variables \( \{\theta, J\} = 1 \) are complex functions

\[
\alpha = i\sqrt{J}e^{-i\theta}, \quad \bar{\alpha} = -i\sqrt{J}e^{i\theta},
\]

with canonical bracket

\[
\{\alpha, \bar{\alpha}\} = -i.
\]

Since \( J = a\bar{a} \), the Hamiltonian of the linear oscillator (8) in these variables is just \( H_0 = a\bar{a} \) (for simplicity we put \( \omega_0 = 1 \) and generic nonlinear Hamiltonian is function of \( H_0 \):

\[
H = H(J) = H(a\bar{a}) = H(H_0).
\]

It determines evolution equation as a nonlinear oscillator

\[
\ddot{\alpha} = -i\frac{\partial H(a\bar{a})}{\partial \bar{a}} = -iH'(\bar{\alpha})\alpha = -i\omega(\bar{\alpha})\alpha,
\]

with frequency \( \omega(\bar{\alpha}) \) depending on value of amplitude, where the last one is an integral of motion.

2.2. Classical f-oscillator

For generic \( H = H(J) = H(a\bar{a}) \) as in (13), by introducing complex variables

\[
\alpha_f = \frac{H(J)}{J\alpha}, \quad \bar{\alpha}_f = \sqrt{\frac{H(J)}{J}}\bar{\alpha},
\]

where \( J = \alpha a \), we express the model in the form of the f-oscillator [14],

\[
H(\alpha_f, \bar{\alpha}_f) = \alpha_f\bar{\alpha}_f,
\]

with the Poisson bracket

\[
\{\alpha_f, \bar{\alpha}_f\} = -i\frac{\partial H(\alpha_f, \bar{\alpha}_f)}{\partial \bar{\alpha}_f} = -i\omega(\alpha_f, \bar{\alpha}_f)
\]

and evolution determined by the same frequency as in (14)

\[
\ddot{\alpha}_f = -i\omega\alpha_f.
\]

2.3. Quantum f-oscillator

Quantization of this system replaces complex variables \( \alpha, \bar{\alpha} \) with bosonic operators \( a, a^+ \), \( \{a, a^+\} = 1 \), the action variable \( J \) with the number operator \( N = a^+a \), and classical Hamiltonian function \( H(J) \) with unique Hermitian quantum operator \( H(N) \). In terms of the last one we define new operators as

\[
\alpha_f = a\sqrt{\frac{H(N)}{N}} = \sqrt{\frac{H(N+1)}{N+1}}a^+,
\]

\[
\alpha_f^+ = a^+\sqrt{\frac{H(N+1)}{N+1}} = \frac{H(N)}{N}a
\]

so that

\[
\alpha_f^+\alpha_f = H(N), \quad \alpha_f\alpha_f^+ = H(N+I)
\]

and

\[
\{\alpha_f, \alpha_f^+\} = H(N+I) - H(N).
\]

The Hamiltonian operator of the corresponding quantum f-oscillator is introduced as [14],

\[
\mathcal{H} = \frac{\alpha_f a_f^+ + \alpha_f^+ a_f}{2}.
\]

In terms of \( H(N) \) operators it becomes the operator

\[
\mathcal{H} = \frac{1}{2}[H(N) + H(N+I)].
\]
with discrete energy spectrum

\[ E_n = \frac{1}{2} [H(n) + H(n + 1)]. \quad (24) \]

### 2.4. Semi-relativistic oscillator as quantum f-oscillator

As an example here we consider the semi-relativistic harmonic oscillator with energy

\[ E(p) = \sqrt{m^2 c^4 + c^2 \left(p^2 + m^2 \omega_0^2 x^2\right)}. \quad (25) \]

in non-relativistic limit \( c \to \infty \) becoming the usual harmonic oscillator

\[ E(p) \approx mc^2 + \frac{1}{2m} \left(p^2 + m^2 \omega_0^2 x^2\right) + O\left(\frac{1}{c}\right). \quad (26) \]

This type of dispersion appears in several physical applications. First is the problem of a relativistic electron in a magnetic field: the relativistic Landau levels problem [17]. Another class of applications is the relativistic harmonic oscillator model of hadrons to explain magnetic moments of baryons and hadron spectroscopy [18].

In terms of action variables the Hamiltonian function is

\[ H(J) = mc^2 \sqrt{1 + \frac{2\omega_0}{mc^2} J}. \quad (27) \]

and in terms of complex variables (11) we have nonlinear oscillator

\[ H(a\bar{a}) = mc^2 \sqrt{1 + \frac{2\omega_0}{mc^2} a\bar{a}}, \quad (28) \]

with nonlinear frequency

\[ \omega(J) = \frac{\partial H(J)}{\partial J} = \frac{\omega_0}{\sqrt{1 + \frac{2\omega_0}{mc^2} J}}. \quad (29) \]

In the non-relativistic limit it reduces to the linear oscillator frequency \( \omega_0 \). Introducing

\[ a_f = \sqrt{m^2 c^4 + 2mc^2 \omega_0 a\bar{a}} \sqrt{a\bar{a}} - \omega_0 \frac{mc^2}{|a_f|^2}, \quad \alpha_f = \sqrt{m^2 c^4 + 2mc^2 \omega_0 a\bar{a}} \sqrt{a\bar{a}} \quad (30) \]

with Poisson brackets

\[ \{a_f, \alpha_f\} = -i\omega_0 \frac{mc^2}{|a_f|^2}, \quad (31) \]

we get the classical f-oscillator form of the model

\[ H(a_f, \bar{a}_f) = a_f \bar{a}_f. \quad (32) \]

The evolution is determined by equation

\[ \dot{a}_f = -i\omega \left(\alpha_f^2\right) a_f, \quad (33) \]

where the frequency is the nonlinear function depending on amplitude

\[ \omega(\alpha_f^2) = \omega_0 \frac{mc^2}{|a_f|^2}. \quad (34) \]

When \( c \to \infty \) it gives

\[ \omega \approx \omega_0 \left(1 - \omega_0 \frac{mc^2}{|a_f|^2}\right), \quad (35) \]

so that the linear oscillator is recovered at \( c = \infty \). The next order correction in \( 1/c \) is just a quadratic nonlinearity in amplitude. This type of nonlinearity is very specific and is described by the cubic nonlinear Schrödinger equation (NLS) as generic integrable nonlinear envelope soliton equation [19]. This means that the first relativistic correction to the nonlinear dispersion (35) will produce the NLS equation.

### 2.4.1. Quantization of semi-relativistic oscillator

Introducing operators

\[ a_f = a \sqrt{m^2 c^4 + 2mc^2 \omega_0 N} \]

\[ a_f = a \sqrt{m^2 c^4 + 2mc^2 \omega_0 (N + 1)} \]

we find relations

\[ a_f a_f^+ = m^2 c^4 + 2mc^2 \omega_0 N, \quad (36) \]

\[ a_f a_f^+ = m^2 c^4 + 2mc^2 \omega_0 (N + 1) \]

and commutator

\[ [a, a^+] = \sqrt{m^2 c^4 + 2mc^2 \omega_0 (N + 1)} - m^2 c^4 + 2mc^2 \omega_0 N. \quad (37) \]

Then the Hamiltonian is operator

\[ H = \frac{1}{2} \left[\sqrt{m^2 c^4 + 2mc^2 \omega_0 (N + 1)} - m^2 c^4 + 2mc^2 \omega_0 N\right]. \quad (38) \]

with discrete spectrum

\[ E_n = \frac{1}{2} \left[\sqrt{m^2 c^4 + 2mc^2 \omega_0 (n + 1)} - m^2 c^4 + 2mc^2 \omega_0 n\right]. \quad (39) \]
3. Classical and quantum symmetric q-oscillator

Here we briefly reproduce the main formulas for the classical and quantum q-oscillator [12, 13].

3.1. Classical symmetric q-oscillator

In terms of complex variables
\[ \alpha = \frac{x + ip}{\sqrt{2}}, \quad \bar{\alpha} = \frac{x - ip}{\sqrt{2}} \]
the Hamilton function is
\[ H_q(\alpha, \bar{\alpha}) = \frac{\sinh (\lambda \bar{\alpha})}{\sinh \lambda}, \]
with Poisson bracket
\[ \{ \alpha, \bar{\alpha} \} = -i, \]
and evolution equations
\[ \dot{\alpha} = -i \omega_q \alpha, \quad \dot{\bar{\alpha}} = i \omega_q \bar{\alpha}. \]

The action-angle variables are defined as
\[ \alpha = i \sqrt{J} e^{-i \theta}, \quad \bar{\alpha} = -i \sqrt{J} e^{i \theta} \]
with bracket \( \{ \theta, J \} = 1 \), so that the Hamiltonian function depends only on \( J \),
\[ H_q(J) = \frac{\sinh (\lambda J)}{\sinh \lambda}. \]

Then the nonlinear frequency depends exponentially on amplitude and the energy
\[ \omega_q(J) = \frac{\partial H(J)}{\partial J} = \frac{\lambda}{\sinh \lambda} \cosh (\lambda J). \]

3.1.1. Quantum symmetric q-oscillator. The standard creation and annihilation operators \( a \) and \( a^\dagger \) with commutator \( [a, a^\dagger] = 1 \) in the Fock basis \( \{ |n\rangle \} \), \( n = 0, 1, 2 \ldots \)
determine the number operator \( N = a^\dagger a \) and symmetric q-number operator
\[ [N]_q = \frac{q^N - q^{-N}}{q - q^{-1}} = \frac{\sinh \lambda N}{\sinh \lambda}, \]
where \( q \equiv e^i \). By transformation [12, 20, 21]
\[ a_f = a \sqrt{\frac{[N]_q}{N}} = \sqrt{\frac{[N + I]_q}{N + I}}, \quad a_f^\dagger = a^\dagger \sqrt{\frac{[N + I]_q}{N + I}} \]
so that
\[ a_f^\dagger a_f = [N]_q, \quad a_f a_f^\dagger = [N + I]_q \]
and
\[ [a_f, a_f^\dagger] = [N + I]_q - [N]_q \]
the Hamiltonian is represented in terms of symmetric q-number operators
\[ H = \frac{a_f a_f^\dagger + a_f^\dagger a_f}{2} = \frac{1}{2} ([N]_q + [N + I]_q) \]
and the spectrum is \([6-8] \)
\[ E_n = \frac{1}{2} ([n]_q + [n + 1]_q) = \frac{1}{2} \sinh \left( \frac{n + \frac{1}{2}}{2} \right). \]

4. The Schrödinger and complex Burgers equations for symmetric q-oscillator dispersion

4.1. q-Schrödinger equation

The first quantization of the q-oscillator is described by the linear Schrödinger equation with Hamiltonian
\[ H_q = \frac{1}{2} \sinh \lambda \left( -\frac{\hbar^2}{m} \frac{d^2}{dx^2} + k x^2 \right). \]

For free q-particle, when the oscillator coupling constant \( k = 0 \), we have the Hamiltonian
\[ H_{0q} = \frac{1}{2} \sinh \lambda \left( -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \right), \]
which determines the linear Schrödinger equation with nonlinear dispersion
\[ i \hbar \frac{\partial \Psi}{\partial t} = \frac{1}{2} \sinh \lambda \left( -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \right) \Psi. \]

We can call it a q-Schrödinger equation.

4.2. Symmetry operators and solutions

Operators of the time and space translations
\[ P_0 = i \hbar \frac{\partial}{\partial t}, \quad P_x = -i \hbar \frac{\partial}{\partial x} \]
commute with the Schrödinger operator
\[ S = i \hbar \frac{\partial}{\partial \theta} - H_{0q} = i \hbar \frac{\partial}{\partial \theta} - \frac{1}{\sinh \lambda} \sinh \left( -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \right). \]

Operators of the space translations
\( P_x, S \) are also commuting with \( S \), \([K, S] = 0 \). Commuting it with space and time translations we obtain the following algebra of symmetry operators
\[ [P_0, P_x] = 0, \quad [P_0, K] = -i \hbar, \]
\[ [P_x, K] = -\frac{\lambda}{m} \sinh \lambda \cosh \lambda \left( \frac{P_0}{m} \right). \]
An operator commutative with Schrödinger operator determines the dynamical symmetry [31]. If \( \Psi \) is a solution of (57) and \( W \) is an operator, so that \([W, S] = 0\) then \( S \Psi \) is also a solution of (57). Then, as follows, \( K \) operator can generate new solutions of (57).

In the limit \( \lambda \rightarrow 0 \) the boost operator (60) reduces to the Galilean boost

\[
K = x + \frac{i \hbar t}{m} \frac{d}{dx}
\]

and \( q \)-deformed symmetry algebra (61) to the usual non-relativistic algebra of the Galilean group [31].

4.2.1. \( q \)-Polynomial solutions. For given classical dispersion

\[
E(p) = \frac{1}{\sinh \lambda} \sinh \left( \frac{p^2}{2m} \right)
\]

we define the plane wave solution as a generating function of \( q \)-Kampe de Feriet polynomials \( H_n^{(q)}(x, t) \). \( q = e^\epsilon \),

\[
e^\frac{i}{\hbar} (\ln E(p) - \epsilon) = \sum_{n=0}^{\infty} \frac{1}{n!} \frac{h^2}{2m} x^n H_n^{(q)}(x, t).
\]

The polynomials

\[
H_n^{(q)}(x, t) = \exp \left( -\frac{i \hbar^2}{2m \sinh \lambda} \left( -\lambda \frac{d^2}{dx^2} \right) \right) x^n
\]

are solutions of (57) with initial value \( H_n^{(q)}(x, 0) = x^n \). From commutativity \([S, K] = 0\), operator \( K \) evolves according to the Heisenberg equation

\[
i\hbar \frac{d}{dt} H_0^{(q)} = \left[ H_0^{(q)}, K \right]
\]

and has the form

\[
K(t) = e^{-\frac{i}{\hbar} H_0^{(q)} t} K(0) e^{\frac{i}{\hbar} H_0^{(q)} t} = e^{-\frac{i}{\hbar} \sum_{l=1}^{\infty} x^l l!} K(0) e^{\frac{i}{\hbar} \sum_{l=1}^{\infty} x^l l!}.
\]

From this it follows that operator \( K \) generates an infinite hierarchy of polynomial solutions according to the recursion

\[
K H_n^{(q)}(x, t) = K e^{-\frac{i}{\hbar} H_0^{(q)} t} x^n = e^{-\frac{i}{\hbar} \sum_{l=1}^{\infty} x^l l!} K(0) e^{\frac{i}{\hbar} \sum_{l=1}^{\infty} x^l l!} = H_{n+1}^{(q)}(x, t),
\]

and the first few polynomials are

\[
H_0^{(q)} = x,
\]

\[
H_1^{(q)}(x) = x^2 + \frac{i \hbar}{m} \frac{\lambda}{\sinh \lambda} t,
\]

\[
H_2^{(q)}(x) = x^3 + \frac{3}{2} \frac{\hbar^2}{m^2 \sinh^2 \lambda} t^2,
\]

\[
H_3^{(q)}(x) = x^4 + \frac{3}{2} \frac{\hbar^2}{m^2 \sinh^2 \lambda} t^2 + \frac{\hbar^2}{m^2 \sinh^2 \lambda} x^2 t,
\]

\[
H_4^{(q)}(x) = x^5 + \frac{5}{2} \frac{\hbar^2}{m^2 \sinh^2 \lambda} t^2 + \frac{15}{2} \frac{\hbar^2}{m^2 \sinh^2 \lambda} x^2 t^2,
\]

\[
H_5^{(q)}(x) = x^6 + \frac{15}{2} \frac{\hbar^2}{m^2 \sinh^2 \lambda} t^2 + \frac{45}{2} \frac{\hbar^2}{m^2 \sinh^2 \lambda} x^2 t^2,
\]
where \( F = S - i\hbar R \) is the complex potential, with real and imaginary parts as the classical and quantum velocities

\[
V = V_c + iV_q = \frac{1}{m} S_c - i\frac{\hbar}{m} R_c. \tag{82}
\]

Then (80) becomes the quantum \( q \)-Hamilton–Jacobi equation:

\[
\frac{\partial F}{\partial t} + \frac{1}{\sinh \lambda} \sinh \left( \frac{\lambda}{2m} \left( -i\hbar \frac{\partial}{\partial x} + F \right) \right)^2 \cdot 1 = 0. \tag{83}
\]

In the classical (dispersionless) limit \( h \to 0 \) the quantum velocity \( V_q \) vanishes and the complex potential reduces to the real velocity potential \( F = S \), so that (83) becomes the classical \( q \)-Hamilton–Jacobi equation for action \( S \):

\[
\frac{\partial S}{\partial t} + \frac{1}{\sinh \lambda} \sinh \left( \frac{\lambda}{2m} \left( \frac{\partial S}{\partial x} \right)^2 \right) = 0. \tag{84}
\]

Differentiating (80) we have nonlinear complex \( q \)-Burgers type equation for the complex velocity (complex \( q \)–Madelung equation)

\[
\frac{\partial V}{\partial t} + \frac{1}{m \sinh \lambda} \frac{\partial}{\partial x} \sinh \left( \frac{\lambda}{2m} \left( -i\hbar \frac{\partial}{\partial x} + mV \right)^2 \right) \cdot 1. \tag{85}
\]

In the classical limit it gives the Newton equation in the hydrodynamic form

\[
\frac{\partial V_c}{\partial t} + \frac{\lambda}{\sinh \lambda} V_c \cosh \left( \frac{\lambda}{2m} \frac{mV_c^2}{2} \right) \frac{\partial V_c}{\partial x} = 0, \tag{86}
\]

which is just a differentiation of the classical Hamilton–Jacobi equation (84). Equation (86) has an implicit general solution

\[
V_c(x, t) = f \left( x - V_c(t) \frac{\lambda}{\sinh \lambda} \cosh \left( \frac{\lambda m V_c^2}{2} \right) \right) \tag{87}
\]

where \( f \) is an arbitrary function, and develops shock at a critical time when derivative \( (V_c)_x \) is blowing up.

### 5.1. Bäcklund transformation for complex \( q \)-Burgers equation

As we have seen, using boost transformation (60) from a given solution \( \Psi \) of the \( q \)-Schrödinger equation (57) we can generate another solution as

\[
\Psi_2 = KP \left[ x + \frac{i\hbar}{m \sinh \lambda} \cosh \left( \frac{\lambda h^2}{2m} \frac{d^2}{dx^2} \right) \frac{d}{dx} \right] \Psi. \tag{88}
\]

By using identity

\[
\Psi^{-1} G \left( -i\hbar \frac{\partial}{\partial x} \right) \Psi = G \left( -i\hbar \frac{\partial}{\partial x} + mV \right) \cdot 1 \tag{89}
\]

for complex velocities \( V_a = -\frac{\hbar}{m} \ln \Psi_a, \ (a = 1, 2) \), for complex \( q \)-Burger equation (85) we obtain the Bäcklund transformation

\[
V_a = V_1 - \frac{\hbar}{m} \frac{\partial}{\partial x} \ln \left( x - \frac{\lambda}{\sinh \lambda} \cosh \left( \frac{\lambda}{2m} (-i\hbar \frac{\partial}{\partial x} + mV)^2 \right) \right) \cdot V_1. \tag{90}
\]

It is noted that in the classical limit \( h \to 0 \), \( V \to V_c \) the above Bäcklund transformation reduces to the trivial identity \( V_1 = V_2 \).

### 6. Integrable nonlinear \( q \)-Schrödinger equation

In previous sections we have studied \( q \)-Schrödinger equation determined by hyperbolic sine dispersion. By adding the oscillator coupling term it becomes an exactly solvable \( q \)-oscillator equation (55). Here we show that from this dispersion it is also possible to construct an NLS type integrable evolution equation. This \( q \)-NLS equation in the limit \( q \to 1 \) or \( \lambda \to 0 \) reduces to the NLS equation. It is interesting to note that by expansion in powers of \( \lambda \) then we have an infinite set of NLS type equations integrable at arbitrary order of deformation \( q \).

#### 6.1. \( q \)-nonlinear \( q \)-Schrödinger equation

Dispersion formula for linear \( q \)-Schrödinger equation (57) expanded to series in \( p^2 \) is

\[
E(p) = \frac{1}{\sinh \lambda} \sinh \left( \frac{\lambda p^2}{2m} \right)
= \frac{\lambda}{\sinh \lambda} \frac{p^2}{2m} + \frac{\lambda^3}{3! \sinh \lambda} \left( \frac{p^2}{2m} \right)^3 + ...	ag{91}
\]

This may be used to construct a linear \( q \)-Schrödinger equation as a formal power series

\[
i\hbar \frac{\partial}{\partial t} \psi = \left[ \frac{\lambda}{\sinh \lambda} \left( \frac{-\hbar^2}{2m} \frac{d^2}{dx^2} \right) \right. + \left. \frac{\lambda^3}{3! \sinh \lambda} \left( \frac{-\hbar^2}{2m} \frac{d^2}{dx^2} \right)^3 + ... \right] \psi \tag{92}
\]

Combining two complex conjugate versions of this equation together we have the system

\[
i\sigma_3 \left( \frac{\psi}{\psi} \right)_t = \frac{1}{\sinh \lambda} \sinh \left( \frac{-\hbar^2}{2m} \left( i\sigma_3 \frac{d}{dx} \right)^2 \right) \left( \frac{\psi}{\psi} \right). \tag{93}
\]

Following the general procedure described in appendix A one may proceed further: by replacing the derivative operator \( R_0 = i\sigma_3 \frac{d}{dx} \) as momenta to the full recursion operator \( R \) (A.2), one obtains an integrable nonlinear \( q \)-Schrödinger...
equation (\(q\)-NLS)
\[
\iota \sigma \frac{\psi}{\psi} = \frac{1}{\sinh \lambda} \sinh \left( \lambda \frac{\hbar^2}{2m} R^2 \right) \frac{\psi}{\psi},
\]
(94)

6.1.1. The linear problem. Applying the general result of appendix A to the above \(q\)-deformed non-relativistic dispersion, we have the next linear problem (the Lax representation) for equation (94)
\[
\frac{\partial}{\partial x} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} -\frac{i}{2} p & -\kappa^2 \psi \\ \frac{i}{2} p & 0 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix},
\]
(95)
\[
\frac{\partial}{\partial t} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} -i \lambda & -\kappa^2 \bar{C} \\ -i \lambda & 0 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix},
\]
(96)
where
\[
\begin{aligned}
\frac{C}{\lambda} &= \sinh \frac{\lambda}{2m} R^2 - \sinh \frac{\lambda}{2m} p^2 \frac{\psi}{\psi}, \\
A &= -\frac{1}{2} \sinh \frac{\lambda}{2m} p^2 - \kappa^2 \left( f^2 \psi - f^2 \bar{\psi} \right) \\
&\quad \times \sinh \frac{\lambda}{2m} R^2 - \sinh \frac{\lambda}{2m} p^2 \frac{\psi}{\psi}.
\end{aligned}
\]
(97)
(98)

and the spectral parameter \(p\) has the meaning of the classical momentum. The model is an integrable nonlinear \(q\)-Schrödinger equation with \(q\)-deformed dispersion as well as the nonlinear terms. In the limit \(\lambda \to 0\) it reduces to standard NLS model (A.4). The last one as a universal integrable equation describing envelope modulation has appeared in many applications, especially in nonlinear optics. It admits \(N\)-soliton solutions, higher symmetries etc [19]. A remarkable property of our model (94) is that it generalizes the NLS model in a very special way. If we expand it in \(\lambda\), then at every order of \(\lambda\) we get an integrable system. This means that we have integrable corrections to the NLS equation at any order of \(\lambda\). Due to the symmetry \(\lambda \to -\lambda\) of (94) only even powers of \(\lambda\) appear in the expansion. Then the lowest corrections are given by the integrable NLS model with sixth-order dispersion \(\psi_{xxxxxx}\) and up to 13th order nonlinearity
\[
\iota \sigma \frac{\psi}{\psi} = \frac{\hbar^2}{2m} R^2 \frac{\psi}{\psi} + \frac{\lambda^2}{6} \left( -\frac{\hbar^2}{2m} R^2 + \frac{\hbar^6}{(2m)^3} R^6 \right) \frac{\psi}{\psi} + O(\lambda^4).
\]
(99)

7. Hydrodynamic flow in bounded domain

As a next variation on the subject here we consider hydrodynamical problem related with motion in double connected domain. This problem can naturally be formulated in terms of \(q\)-calculus and as we will see, for the point vortex motion in annulus it provides an example of nonlinear oscillator, formulated as an \(f\)-oscillator.

7.1. Hydrodynamic flow in bounded domain

For incompressible and irrotational flow in a domain bounded by curve \(C\), the problem is to find analytic function \(F(z)\) with boundary condition
\[
3Fk = \psi |_{C} = 0,
\]
where \(\psi\) is the stream function. Then the normal velocity vanishes at boundary \(\psi |_{C} = 0\).

7.2. Milne–Thomson’s one circle theorem

For a given flow in plane with complex potential \(f(z)\), introduction of boundary circle at the origin \(C: |z| = r\) produces the flow with complex potential [24]
\[
F(z) = f(z) + \hat{f} \left( \frac{r^2}{z} \right),
\]
(100)
where \(Q = \frac{\iota}{\alpha} f(z) = \sum_{n=-\infty}^{\infty} f(Q^n z)\) is flow in even annular image domain, \(\hat{f}(\frac{r^2}{z}) = \sum_{n=-\infty}^{\infty} f(Q^n z)\) is the flow in odd annular image domain.

From (100) it follows that \(\hat{f}(Qz) = f(Qz)\), which implies that the complex potential is \(Q\)-periodic function \(F(Qz) = F(z)\). Depending on the number and position of vortices or other objects, we fix singularity of this function in terms of \(q\)-elementary functions [22, 27].

7.4. Wedge theorem

Here we are going to formulate some new theorems in wedge domain. For a given flow in plane with complex potential \(f(z)\), introduction of boundary wedge with angle \(\alpha = 2\pi/N = \pi/n\), where \(N = 2n\) is a positive even number, produces the flow with complex potential
\[
F_q(z) = f(z) + \hat{f} \left( q^2 z \right) + f \left( q^2 z \right) + ... + f \left( q^{2(n-1)} z \right),
\]
(101)
\[
+ \hat{f} \left( q^2 z \right) + \hat{f} \left( q^2 z \right) + ... + \hat{f} \left( q^{2(n-1)} z \right),
\]
(102)
or briefly
\[
F_q(z) = \sum_{k=0}^{n-1} f \left( q^{2k} z \right) + \sum_{k=0}^{n-1} \hat{f} \left( q^{2k} z \right),
\]
(103)
where \( q = e^{i \pi/2} = e^{i \pi} \) is the primitive root of unity: \( q^n = q^{2n} = 1 \). For proof of this theorem see appendix B.

Here we notice that the complex potential (103) is \( q^2 \) periodic analytic function \( F_q(z) = F_q(z) \), while the complex velocity \( \overrightarrow{V}(z) = i F_q(z) / dz \) is the scale invariant analytic function \( \overrightarrow{V}(q^-z) = q^{-2} \overrightarrow{V}(z) \).

7.4.1. Vortex kaleidoscope. As an example, we consider single vortex in the wedge at point \( z_0 \):

\[
F(z) = \frac{i \Gamma}{2 \pi} \ln (z - z_0).
\]

7.4.2. Complex potential. For single vortex in the wedge at point \( z_0, z_0, z_0 q^2, z_0 q^4, \ldots, z_0 q^{2(n-1)} \) and with negative strength at points \( z_0, z_0 q^2, z_0 q^4, \ldots, z_0 q^{2(n-1)} \). Positive images are just rotations of original vortex position \( z_0 \) on angles \( \pi/2, 3 \pi/2, 5 \pi/2 \), etc., while negative images are rotations of the reflected vortex position \( \tilde{z}_0 \) on the same angles. This expression can be drastically simplified due to the next identity

\[
(z - z_0) (z - z_0 q^2) (z - z_0 q^4) \ldots (z - z_0 q^{2(n-1)}) = z^n - z_0^n.
\]

Comparing with vortex kaleidoscope (107) we observe doubling of images by reflection in circle \( r \).

7.5. Circular wedge theorem

Here we consider circular wedge with angle \( \alpha = 2 \pi/N = \pi/n \), bounded by lines \( \Gamma_1: z = x \) and \( \Gamma_2: z = x e^{i \pi/2} \) and the circular boundary \( \Gamma_3: z = r e^{i \theta}, 0 < \theta < \alpha \). Then, the flow bounded by such domain is

\[
F_q(z) = \sum_{k=0}^{n-1} \left[ f \left( q^{k} z \right) + \tilde{f} \left( q^{k} z \right) \right] + \sum_{k=0}^{n-1} \left[ \frac{r^2}{q^{k^2} z} \right] + \frac{r^2}{q^{k^2} z}.
\]

The proof is similar to the above one and shows that the imaginary part of \( F(z) \) vanishes at boundaries \( \Gamma_1, \Gamma_2 \) and \( \Gamma_3 \). The theorem could be considered as combination of Milne–Thomson’s one circle theorem with the wedge theorem.

7.5.1. Doubled vortex kaleidoscope. For single vortex in circular wedge after some calculations and simplifications we obtain

\[
F_q(z) = \frac{i \Gamma}{2 \pi} \ln \left( \frac{z^n - z_0^n}{z^n - z_0^n} \right).
\]

In explicit form we obtain

\[
F(z) = \sum_{m=-\infty}^{\infty} \sum_{k=0}^{n-1} \left[ f \left( q^{m} q^{k^2} z \right) + \tilde{f} \left( q^{m} q^{k^2} z \right) \right] + \frac{r^2}{q^{m^2} z} + \frac{r^2}{q^{m^2} z}.
\]

It is noticed that in this case we have \( q \)-calculus with two different bases. The first one \( q = r^2/r_2^2 \) is a real number relating an infinite number of reflections in both circular boundaries. The second one \( q = e^{2 \pi i} \) is a complex unitary number with finite number of reflections \( n \). The complex
potential here is a double \( q \), \( Q \)—periodic analytic function:
\[
F(q; z) = F(z), \quad F(Qz) = F(z).
\] (115)

7.6.1. Self-similar infinite vortex kaleidoscope. For single vortex in annular domain the complex velocity at point \( z \) in the double circular wedge we get the result
\[
F(z) = \frac{i^q}{2\pi} \sum_{m=-\infty}^{\infty} \ln \left( \frac{(z - z_0^m)(z - \frac{r_1^m}{z_0} Q^m)(z - \frac{r_2^m}{z_0} Q^m)}{(z - z_0^m)(z - \frac{r_1^m}{z_0} Q^m)(z - \frac{r_2^m}{z_0} Q^m)} \right).
\] (116)

For \( n = 2, q^2 = -1 \) we have a single vortex in first quadrant of annulus and
\[
F(z) = \frac{i^q}{2\pi} \sum_{m=-\infty}^{\infty} \ln \left( \frac{z - z_0^m}{z - z_0^m} \right) \left( \frac{z - \frac{r_1^m}{z_0} Q^m}{z - \frac{r_1^m}{z_0} Q^m} \right).
\] (117)

This function describes self-similar kaleidoscope of infinite set of vortices on \( Q \) geometric lattice. It generalizes the expression for single-vortex images in concentric annular domain considered in [22]. For \( n = 1, q = 1 \), and we have a single vortex in the upper half-plane of annular domain
\[
F(z) = \frac{i^q}{2\pi} \sum_{m=-\infty}^{\infty} \ln \left( \frac{z - z_0^m}{z - z_0^m} \right) \left( \frac{z - \frac{r_1^m}{z_0} Q^m}{z - \frac{r_1^m}{z_0} Q^m} \right).
\] (118)

or
\[
F(z) = \frac{i^q}{2\pi} \sum_{m=-\infty}^{\infty} \ln \left( \frac{z - z_0^m}{z - z_0^m} \right) \left( \frac{z - \frac{r_1^m}{z_0} Q^m}{z - \frac{r_1^m}{z_0} Q^m} \right) \left( \frac{z - \frac{r_1^m}{z_0} Q^m}{z - \frac{r_1^m}{z_0} Q^m} \right).
\] (119)

This formula demonstrates how vortices are reflected for every value of \( m \).

8. Vortex in annular domain as \( f \)-oscillator

As an application of the above formulas, here we consider the point vortex problem in annular domain as a nonlinear oscillator, or as the specific form of the \( f \)-oscillator.

8.1. Vortex rotation in annulus as nonlinear \( q \)-oscillator

For a single vortex in annular domain the complex velocity at the vortex position is determined by [22],
\[
\dot{z}_0 = x_0 + i y_0 = V_0(z) \bigg|_{z=z_0} \quad (120)
\]
with canonical bracket
\[ \{ z_0, \bar{z}_0 \} = -\frac{2i}{J}, \]
and Hamiltonian function
\[
H(z_0, \bar{z}_0) = \frac{J^2}{4\pi} \ln \left| e_J \left( \frac{1z_0^2}{(1-q)r_1^2} \right) e_J \left( \frac{r_2^2}{(1-q)J} \right) \right|.
\]
where the Jackson \( q \)-exponential function is defined as
\[ e_j(z) = \sum_{n=0}^{\infty} \frac{z^n}{[n]!}. \]
It is entire in \( z \) if \( |q| > 1 \), and admits infinite product representation
\[
\prod_{k=1}^{\infty} \left( 1 - \frac{z}{q^k} \right) = \frac{1}{1 - z} e_q \left( \frac{-z}{1 - q^{-1}} \right).
\]
showing that zeros of this function are ordered in geometric progression with ratio \( q \). By introducing the action-angle variables \( (J, \theta) \)
\[
z_0 = i\sqrt{J} e^{i\theta}, \quad \bar{z}_0 = -i\sqrt{J} e^{i\theta},
\]
we get the Hamiltonian function in terms of action variables \( J \) only
\[
H(J) = \frac{J^2}{4\pi} \ln \left| e_J \left( \frac{J}{(1-q)J} \right) e_J \left( \frac{r_2^2}{(1-q)J} \right) \right|.
\]
and the frequency of rotation
\[
\omega(J) = \frac{\partial H(J)}{\partial \theta} = \frac{J}{2\pi(q-1)J} \times \left[ L_n q \left( 1 - \frac{J}{r_1^2} \right) - L_n q \left( 1 - \frac{r_2^2}{J} \right) \right].
\]
The angular momentum then is just \( L = \Gamma J \). To represent our model as an \( f \)-oscillator we introduce complex functions
\[
z_f = \sqrt{\frac{H(z_0, \bar{z}_0)}{z_0 \bar{z}_0}}, \quad \bar{z}_f = \sqrt{\frac{H(z_0, \bar{z}_0)}{z_0 \bar{z}_0}}.
\]
Then we have simply \( f \)-oscillator
\[
H(z_f, \bar{z}_f) = z_f \bar{z}_f,
\]
with Poisson bracket
\[
\{ z_f, \bar{z}_f \} = -\frac{2i}{\Gamma} \frac{\partial H}{\partial \bar{J}} (z_f, \bar{z}_f) = -\frac{2i}{\Gamma} \omega(z_f, \bar{z}_f)
\]
and evolving with the frequency (135)
\[
\dot{z}_f = -i\omega z_f.
\]

### 8.1.1. \( F \)-oscillator quantization of vortex motion

In semiclassical approach, quantization is implemented by Bohr–Zommerfeld quantization rule of replacing \( J \to n+1/2 \). Then the energy spectrum is
\[
E_n = \frac{J^2}{4\pi} \ln \left| e_n \left( \frac{(n + \frac{1}{2})J}{(1-q)n} \right) e_n \left( \frac{r_2^2}{(1-q)n + \frac{1}{2}} \right) \right|.
\]

The \( f \)-oscillator quantization of this system, replaces complex variables \( z_0 \) with bosonic operators \( [a_\downarrow, a_\uparrow] = 1 \), \( N = a_\downarrow a_\uparrow \). The Hamiltonian of the corresponding \( f \)-oscillator is given by (22), where we define operators (19) in terms of nonlinear operator function (134) \( H(N) \), by replacing \( J \to N \), and spectrum of the system is
\[
E_n = \frac{1}{2} \left[ H(n) + H(n+1) \right].
\]
In a similar way one can study \( N \) vortex polygon rotation in annular domain [22, 23] as a nonlinear \( f \)-oscillator.

### 9. Golden quantum oscillator

As a final variation here we consider two golden ratio bases quantum \( q \)-oscillator. We define creation and annihilation operators \( b \) and \( b^\dagger \) in the Fock basis \( \{|n\} \), \( n = 0, 1, 2 \ldots \) represented by infinite matrices
\[
b = \begin{pmatrix} 0 & \sqrt{F_1} & 0 & \ldots \\
0 & 0 & \sqrt{F_2} & 0 \\
0 & 0 & 0 & \sqrt{F_3} \\
\ldots & \ldots & \ldots & \ldots \end{pmatrix}, \quad b^\dagger = \begin{pmatrix} 0 & 0 & 0 & \ldots \\
0 & \sqrt{F_1} & 0 & \ldots \\
0 & 0 & \sqrt{F_2} & 0 \\
\ldots & \ldots & \ldots & \ldots \end{pmatrix}.
\]
where \( F_n \) are Fibonacci numbers. By introducing the Fibonacci operator as a matrix Binet formula,
\[
F_n = \frac{q^n + q^{-n}}{q - q^{-1}},
\]
where \( N = a_\downarrow a_\uparrow \) is the standard number operator, and \( q, q^\dagger = -q^{-1} \) are solutions of \( q^2 = q + 1, \quad q = 1 + \sqrt{5} \)—is the golden ratio, we find that in the Fock basis the eigenvalues are just Fibonacci numbers
\[
F_n |n\rangle = F_n |n\rangle.
\]
and in the matrix form
\[
F_N = \begin{pmatrix} F_0 & 0 & 0 & \ldots \\
0 & F_1 & 0 & 0 \\
0 & 0 & F_2 & 0 \\
\ldots & \ldots & \ldots & \ldots \end{pmatrix}, \quad F_{N+1} = \begin{pmatrix} F_0 & 0 & 0 & \ldots \\
0 & F_1 & 0 & 0 \\
0 & 0 & F_2 & 0 \\
\ldots & \ldots & \ldots & \ldots \end{pmatrix}.
\]
It satisfies Fibonacci recursion rule \( F_{N+1} + F_N = F_{N+1} \). Then we have
\[
b b^\dagger = F_{N+1}, \quad b^\dagger b = F_N.
\]
and the commutator is
\[ [b, b^\dagger] = F_{N+1} - F_N = F_{N-1}. \]
From the definition of \( F_N \) we get the matrix identity
\[ q^N = q F_N + F_{N-1}, \]
where
\[ q^N = \begin{pmatrix} 1 & 0 & 0 & \ldots \\ 0 & q & 0 & \ldots \\ 0 & 0 & q^2 & 0 \\
\end{pmatrix} \]
and the following deformed commutation relations
\[ b b^\dagger - q b^\dagger b = q^N, \quad b b^\dagger - q^2 b^\dagger b = q^N. \]

The Hamiltonian \([25]\)
\[ H = \frac{\hbar \omega}{2} (b b^\dagger + b^\dagger b) = \frac{\hbar \omega}{2} (F_N + F_{N+1}) = \frac{\hbar \omega}{2} F_{N+2} \]
is diagonal
\[ H = \begin{pmatrix}
\frac{\hbar \omega}{2} F_2 & 0 & 0 & \ldots \\
0 & \frac{\hbar \omega}{2} F_3 & 0 & \ldots \\
0 & 0 & \frac{\hbar \omega}{2} F_4 & 0 \\
\cdots & \cdots & \cdots & \cdots \\
\end{pmatrix} \]
and gives the energy spectrum as the Fibonacci sequence
\[ E_n = \frac{\hbar \omega}{2} F_{N+2}. \]
These energy levels satisfy the Fibonacci three-term relations
\[ E_{n+1} = E_n + E_{n-1} \]
and the difference between levels
\[ \Delta E_n = E_{n+1} - E_n = \frac{\hbar \omega}{2} F_{n+1}. \]
is growing as Fibonacci sequence. Then the relative distance
\[ \frac{\Delta E_n}{E_n} = \frac{F_{n+1}}{F_{n+2}} \]
for asymptotic states \( n \to \infty \) is given just by the golden ratio
\[ \lim_{n \to \infty} \frac{\Delta E_n}{E_n} = \frac{1}{\varphi}. \]

This behavior drastically differs from the harmonic oscillator and shows that there is no simple classical limit for this golden oscillator. In fact, the Hamiltonian function for corresponding classical system becomes complex valued.

By transformation
\[ b = a \sqrt{\frac{F_N}{N}} = \sqrt{\frac{F_{N+1}}{N+1}} a, \]
\[ b^\dagger = a^\dagger \sqrt{\frac{F_N}{N}} = a^\dagger \sqrt{\frac{F_{N+1}}{N+1}} \]
one can show that eigenstates
\[ |n\rangle_F = \left( b^\dagger \right)^n \left( \frac{1}{\sqrt{F_n!}} \right) |0\rangle_F \]
coincide with the Fock states \( |n\rangle \). Then we have
\[ b^\dagger |n\rangle_F = \sqrt{F_{n+1}} |n+1\rangle_F, \]
\[ b |n\rangle_F = \sqrt{F_n} |n-1\rangle_F. \]

Here we would like to mention that three-term relations (154) can be generalized by introducing free coefficients and corresponding oscillators are known as Fibonacci oscillators [32]. See also [33] for quasi-Fibonacci oscillators. In this generalized form the spectrum is given by Fibonacci polynomials and Binet formula can be interpreted as \( q \)-number with two basis \( q \) and \( p \). The spectrum is given just by Fibonacci numbers only in the case, when the basis is determined by the golden ratio: \( q = \varphi, \quad p = \varphi' \). We discuss these relations in detail in our paper [25].

9.1.1. Golden coherent states. We define the golden coherent states as eigenstates
\[ b |\beta\rangle_F = \beta |\beta\rangle_F. \]

Expanding these states in the Fock space \( |\beta\rangle = \sum_{n=0}^{\infty} c_n |n\rangle \) we find recurrence relation
\[ c_{n+1} \sqrt{F_{n+1}} = c_n \beta, \]
giving
\[ c_n = \frac{\beta^n}{\sqrt{F_n!}} c_0. \]

We fix \( c_0 \) by normalization condition \( \langle \beta | \beta \rangle = 1 \) so that
\[ |\beta|^2 = \left( \sum_{n=0}^{\infty} \frac{\beta^n}{F_n!} \right)^{-1} = \left( e^{|\beta|} \right)^{-1}, \]
where we have introduced the Fibonacci exponential function
\[ e^{|\beta|} = \sum_{n=0}^{\infty} \frac{\beta^n}{F_n!}, \]
which, as is easy to see, is the entire function of \( z \). As a result we get normalized coherent state
\[ |\beta\rangle_F = \left( e^{|\beta|} \right)^{-1/2} \sum_{n=0}^{\infty} \frac{\beta^n}{\sqrt{F_n!}} |n\rangle_F. \]
with the scalar product

\[ F(\psi|\phi)_F = \frac{e^{\chi\bar{\phi}}}{(e^{\chi\bar{\phi}})^{1/2}} \left[ (e^{\chi\bar{\phi}})^{1/2} \right] \]  

(167)

9.2.2. Golden Fock–Bargman representation. For an arbitrary state from the Fock space \(|\psi\rangle = \sum_{n=0}^{\infty} c_n |n\rangle_F\) by projection

\[ \langle \beta | \psi \rangle = \left( e^{\chi\bar{\phi}} \right)^{-1/2} \sum_{n=0}^{\infty} c_n \beta^n \sqrt{F_n!} \]  

(168)

we find the analytic wave function

\[ \psi(\beta) = \sum_{n=0}^{\infty} c_n \beta^n \sqrt{F_n!} \]  

(169)

in the golden Fock–Bargman representation. By simple calculation it is easy to see that operators \(b\) and \(b^+\) in this representation are given by

\[ b \rightarrow D^F_b, \quad b^+ \rightarrow \beta, \]  

(170)

where the Binet–Fibonacci complex derivative is defined as

\[ D^F_z \psi(z) = \frac{\psi(qz) - \psi(q^{-1}z)}{(q - q^{-1})z}. \]  

(171)

Action of this derivative on monomial gives just Fibonacci numbers \(D^F_z z^n = F_n z^{n-1}\) and for the Fibonacci exponential function we have \(D^F_z e^z = e^z\). Then the Fibonacci number operator is represented as

\[ F_n \rightarrow \beta D^F_\beta. \]  

(172)

If an analytic function \(\psi(z)\) is scale invariant \(\psi_k(\lambda z) = \lambda^k \psi_k(z)\), then it satisfies equation

\[ D^F_z \psi_k(z) = \frac{\psi_k(qz) - \psi_k(-q^{-1}z)}{(q + q^{-1})z} \]  

(173)

or

\[ zD^F_z \psi_k(z) = F_k \psi_k(z). \]  

(174)

This eigenvalue problem is just the golden Fock–Bargman representation of the Fibonacci operator eigenvalue problem (144), where eigenfunctions

\[ \psi_k(z) = z^k \sqrt{F_k!} \]  

(175)

are scale invariant. However if we look for a general solution of (174), then it is of the form

\[ f_k(z) = z^k A(z) \]  

(176)

where \(A(z)\) is an arbitrary golden-periodic analytic function \(A(qz) = A(-q^{-1}z)\). Such a structure characterizes the quantum fractals [27, 29] and requires additional studies.

Appendix A. NLS hierarchy and \(\Psi\)-NLS

A.1. NLS hierarchy

We consider the NLS hierarchy

\[ i\sigma_3 \left( \frac{\psi}{\tau_{\kappa}} \right) = \mathcal{R} \left( \frac{\psi}{\tau_{\kappa}} \right) \]  

(1.1)

where \(\tau_{\kappa}, N = 1, 2, 3.\.\) is an infinite time hierarchy. Here \(\mathcal{R}\) is the matrix integro-differential operator—the recursion operator of the NLS hierarchy

\[ \mathcal{R} = i\sigma_3 \begin{bmatrix} \partial_\kappa + 2\kappa^2 \int^\kappa \psi & -2\kappa^2 \int^\kappa \psi \\ -2\kappa^2 \int^\kappa \psi & \partial_\kappa + 2\kappa^2 \int^\kappa \psi \end{bmatrix} \]  

(1.2)

and \(\sigma_3\) the Pauli matrix. For the first few members of the hierarchy \(N=1, 2, 3, 4\) this gives

\[ \psi_{\tau_1} = \psi, \]  

(1.3)

\[ i\psi_{\tau_2} + \psi_{\tau_3} + 2\kappa^2 \int^\kappa \psi^2 \psi = 0, \]  

(1.4)

\[ \psi_{\tau_2} + \psi_{\tau_3} + 6\kappa^4 |\psi|^2 \psi_i = 0, \]  

(1.5)

\[ \psi_{\tau_4} = \psi_{\tau_3} + 2\kappa^2 \left( 3\psi_{\tau_3}^2 + \psi_{\tau_3}^2 + 3\psi_{\tau_3} \psi_i^2 + 2 \psi_{\tau_3}^2 \right) \]  

(1.6)

In the linear approximation, when \(\kappa = 0\), the recursion operator is just the momentum operator

\[ \mathcal{R}_0 = i\sigma_3 \frac{\partial}{\partial \kappa} \]  

(1.7)

and the NLS hierarchy (1.1) becomes the linear Schrödinger hierarchy

\[ i\psi_{\tau} = i\partial_\kappa \psi. \]  

(1.8)

Written in the Madelung representation it produces the complex Burgers hierarchy so that this representation plays the role of the complex Cole–Hopf transformation [30]. Every equation of the hierarchy (1.1) is integrable. The linear problem for the \(N\)th equation is given by the Zakharov–
Shabat problem
\[
\frac{\partial}{\partial x} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} -i/2p & -i/2p \\ \psi & \psi \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \mathcal{J}_1 \begin{pmatrix} v_1 \\ v_2 \end{pmatrix},
\]
(A.9)
for the space evolution, and
\[
\frac{\partial}{\partial N} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} -iA_N & -i\kappa \psi \\ C_N & -iA_N \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \mathcal{J}_0 N \begin{pmatrix} v_1 \\ v_2 \end{pmatrix},
\]
(A.10)
for the time part. Coefficient functions \( C_N \) and \( A_N \) are \([28]\),
\[
\begin{align*}
\left( \frac{C_N}{C_N} \right) &= \sum_{k=1}^{N} p^{N-k} R^{k-1} \left( \psi \psi \right) \\
&= \left( p^{N-1} + p^{N-2} R + \cdots + R^{N-1} \right) \left( \psi \psi \right).
\end{align*}
\]
(A.11)
To write this expression in a compact form, by analogy with \( q \)-calculus it is convenient to introduce notation of nonsymmetric \( q \)-number operator
\[
1 + q + q^2 + \cdots + q^{N-1} \equiv [N]_q,
\]
(A.12)
where \( q \) is a linear operator. Hence with operator \( q \equiv R/p \) we have the finite Laurent part in the spectral parameter \( p \)
\[
1 + \frac{R}{p} + \left( \frac{R}{p} \right)^2 + \cdots + \left( \frac{R}{p} \right)^{N-1} \equiv [N]_{R/P}.
\]
(A.13)
Then we have briefly
\[
\left( \frac{C_N}{C_N} \right) = p^{N-1} [N]_{R/P} \left( \psi \psi \right).
\]
(A.14)
In a similar way
\[
A_N = -\frac{p^N}{2} - i\kappa^2 \left( \int x \psi \bar{\psi} \right) - \left( \int x \psi \right) \left( \frac{C_N}{C_N} \right)
\]
(A.15)
and due to (A.14)
\[
A_N = -\frac{p^N}{2} - i\kappa^2 \left( \int x \psi \bar{\psi} \right) - \left( \int x \psi \right) [N]_{R/P} \left( \frac{\psi}{\psi} \right).
\]
(A.16)
Equations (A.10), (A.14) and (A.16) give the time part of the linear problem (the Lax representation) for the \( N \)th flow of NLS hierarchy (A.1).

A.2. General NLS hierarchy equation
For the time \( \tau \) determined by the formal series
\[
\partial_\tau = \sum_{N=0}^{\infty} E_N \partial_{\tau_N},
\]
(A.17)
where \( E_N \) are arbitrary constants, the general NLS hierarchy equation is \([28]\)
\[
\sigma_3 \left( \begin{pmatrix} \psi \\ \bar{\psi} \end{pmatrix} \right) = \left( E_0 + E_1 R + \cdots + E_N R^N + \cdots \right) \left( \begin{pmatrix} \psi \\ \bar{\psi} \end{pmatrix} \right),
\]
(A.18)
\[\text{A.2.1. Linear problem.}\]
Integrability of this equation is associated with the Zakharov–Shabat problem (A.9) and the time evolution
\[
J_0 = \sum_{N=0}^{\infty} E_N J_{0_N} \equiv \left( \begin{array}{cc} -iA & -\kappa^2 \bar{C} \\ C & -iA \end{array} \right).
\]
(A.19)
where
\[
\left( \frac{C}{\bar{C}} \right) = \sum_{N=0}^{\infty} E_N \left( \frac{C_N}{C_N} \right) \\
= \sum_{N=1}^{\infty} E_N p^{N-1} \left( [N]_{R/P} \left( \frac{\psi}{\psi} \right) \right).
\]
(A.20)
In the last equation we have used that for \( N = 0, C_0 = 0 \). Then we have
\[
A = \sum_{N=0}^{\infty} E_N A_N = \frac{1}{2} \sum_{N=0}^{\infty} E_N p^N \\
- i\kappa^2 \left( \int \int x \psi \bar{\psi}, - \int \int x \psi \right) \left( \frac{C}{\bar{C}} \right).
\]
(A.21)

A.2.2. Integrable nonlinearization.
The above equation (A.18) gives integrable nonlinear extension of a linear Schrödinger equation with general analytic dispersion. Let us consider the classical particle system with the energy-momentum relation
\[
E = E(p) = E_0 + E_1 p + E_2 p^2 + \cdots
\]
(A.22)
Then the corresponding time-dependent Schrödinger wave equation is
\[
\hat{H} \left( \frac{\partial}{\partial \tau} \psi \right) = E \left( \frac{\partial}{\partial \tau} \bar{\psi} \right),
\]
(A.23)
where the Hamiltonian operator results from the standard substitution for momentum \( p \rightarrow -i\hbar \frac{\partial}{\partial x} \) in the dispersion (A.22). Equation (A.23) together with its complex conjugate can be rewritten as a system
\[
\hat{H} \left( \frac{\partial}{\partial \tau} \psi \right) = E \left( \frac{\partial}{\partial \tau} \bar{\psi} \right).
\]
(A.24)
The momentum operator here is just the recursion operator (A.7) in the linear approximation \( R_0 = i\sigma_3 \frac{\partial}{\partial \tau} \). Hence (A.24) can be rewritten as the linear Schrödinger equation with an arbitrary analytic dispersion
\[
\hat{H} \left( \frac{\partial}{\partial \tau} \psi \right) = E \left( \frac{\partial}{\partial \tau} \bar{\psi} \right) \left( \begin{array}{cc} \sigma_3 \bar{C} & -\kappa^2 \bar{C} \\ \bar{C} & \sigma_3 \bar{C} \end{array} \right) \left( \begin{array}{cc} \psi \\ \bar{\psi} \end{array} \right).
\]
(A.25)
Then the nonlinear integrable extension of this equation appears as (A.18), which corresponds to the replacement \( R_0 \rightarrow R, (\hbar = 1) \), so that
\[
\sigma_3 \left( \begin{pmatrix} \psi \\ \bar{\psi} \end{pmatrix} \right) = H \left( \begin{array}{cc} E_0 + E_1 R + \cdots + E_N R^N + \cdots \end{array} \right) \left( \begin{array}{cc} \psi \\ \bar{\psi} \end{array} \right).
\]
(A.26)
From this point of view the standard substitution for classical momentum $p \rightarrow -i\hbar \frac{\partial}{\partial x}$ or equivalently $p \rightarrow -i\sigma_1 \frac{\partial}{\partial x} = R_0$ for the equation in spinor form, gives quantization in the form of the linear Schrödinger equation. While substitution $p \rightarrow R$ gives ‘nonlinear quantization’ and the nonlinear Schrödinger hierarchy equation.

### A.2.3. The Lax representation.

The related Lax representation for equation (A.26) is given by (A.20), (A.21). Using definition of $q$-derivative

$$D^q_j f (\zeta) = \frac{f (q\zeta) - f (\zeta)}{(q - 1)\zeta},$$

(A.27)

for operator $q = R/p$ we have relation

$$D^q_j \zeta_j^N = [N]_{R/p} p^{N-1}. \quad (A.28)$$

Then equation (A.20) can be rewritten as

$$\left(\frac{C}{\zeta}\right) = \sum_{N=1}^{\infty} E_N p^{N-1} [N]_{R/p} \left(\frac{\psi}{\tilde{\psi}}\right) \quad (A.29)$$

or using linearity of (A.27) and dispersion (A.22)

$$\left(\frac{C}{\zeta}\right) = D_{R/p} \sum_{N=0}^{\infty} E_N p^{N} \left(\frac{\psi}{\tilde{\psi}}\right) = D_{R/p} E (p) \left(\frac{\psi}{\tilde{\psi}}\right). \quad (A.30)$$

Due to definition (A.27) it gives the simple formula

$$\left(\frac{C}{\zeta}\right) = \frac{E (R) - E (p)}{R - p} \left(\frac{\psi}{\tilde{\psi}}\right), \quad (A.31)$$

where

$$\frac{E (R) - E (p)}{R - p} = E_1 + E_2 (R + p) + E_3 (R^2 + Rp + p^2) + \ldots \quad (A.32)$$

Then for $A$ we obtain

$$A = -\frac{1}{2} E (p) - i\kappa^2 \left(\int^x \psi, -\int^x \tilde{\psi}\right) \times \frac{E (R) - E (p)}{R - p} \left(\frac{\psi}{\tilde{\psi}}\right).$$

(A.33)

Equations (A.31), (A.33) give the Lax representation of the general integrable NLS hierarchy model (A.26). It is worth noting here that special form of the dispersion $E = E (p)$ is fixed by physical problem. In [28] we have constructed semi-relativistic NLS equation. As another application, in section 4 we discuss symmetric $q$-NLS equation. We like to mention here also the paper [34], which discusses the relation between integrable discretization of integrable models and $q$-oscillators.

### Appendix B. Wedge theorem

**Proof:** First we show that $\mathcal{F}_q (z)|_{i_1} = 0$, where $i_1 : \{ z = x + i0 \}$ is the real axis. Substituting $z = x$ to (103) and using identities for even powers

$$q^2 = q^{-2(n-1)} = \bar{q}^{2(n-1)}, \quad (B.1)$$

$$q^4 = q^{-2(n-2)} = \bar{q}^{2(n-2)}, \quad (B.2)$$

$$\ldots \quad (B.3)$$

$$q^{2k} = q^{-2(n-k)} = \bar{q}^{2(n-k)}, \quad (B.4)$$

$$\ldots \quad (B.5)$$

$$q^{2(n-1)} = q^{-2} = q^2, \quad (B.6)$$

we find

$$F_q (z)|_{i_1} = \sum_{k=0}^{n-1} f \left(q^{2k} x\right) + \sum_{k=0}^{n-1} \bar{f} \left(q^{2(n-k)} x\right)$$

$$= \sum_{k=0}^{n-1} f \left(q^{2k} x\right) + \sum_{k=0}^{n-1} \bar{f} \left(q^{2k} x\right), \quad (B.7)$$

where in the second sum we have changed summation order by substitution $n - k \rightarrow k$. This shows that on the real line the complex potential is pure real and imaginary part vanishes.

Now we show that $\mathcal{F}_q (z)|_{i_2} = 0$, where $i_2 : \{ z = x e^{i \pi} = q x \}$ is the second boundary line. Substituting we have

$$F_q (z)|_{i_2} = \sum_{k=0}^{n-1} f \left(q^{2k+1} x\right) + \sum_{k=0}^{n-1} \bar{f} \left(q^{2k+1} x\right). \quad (B.8)$$

By identities for odd powers

$$q = q^{-2(n-1)} = \bar{q}^{2n-1}, \quad (B.9)$$

$$q^3 = q^{-2(n-3)} = \bar{q}^{2n-3}, \quad (B.10)$$

$$\ldots \quad (B.11)$$

$$q^{2n-3} = q^{-1} = q^3, \quad (B.12)$$

$$q^{2n-1} = q^{-1} = \bar{q}, \quad (B.13)$$

and as follows $q^{2k+1} = q^{-2n+2k+1} = \bar{q}^{2n-2k-1}$, we rewrite the sum

$$F_q (z)|_{i_2} = \sum_{k=0}^{n-1} f \left(q^{2k+1} x\right) + \sum_{k=0}^{n-1} \bar{f} \left(q^{2k+1} x\right). \quad (B.14)$$

After changing order of summation in the second sum and shifting summation index we finally get

$$F_q (z)|_{i_2} = \sum_{k=0}^{n-1} f \left(q^{2k+1} x\right) + \sum_{k=0}^{n-1} \bar{f} \left(q^{2k+1} x\right). \quad (B.15)$$

which shows that the stream function vanishes at the boundary. This completes the proof of the wedge theorem.
