The dynamics of relative entropy and $l_1$-norm of coherence, as well as, the Wigner-Yanase skew and quantum Fisher information are studied for a time-dependent coupled XY spin chain in presence of a time-dependent transverse magnetic field. Independent of the initial state of the system and while the relative entropy of coherence, $l_1$-norm of coherence, and quantum Fisher information are incapable, surprisingly, the dynamic Wigner-Yanase skew information can truly spotlight the equilibrium critical point. We also observe that when the system is quenched to the critical point, these quantities show suppressions and revivals. Moreover, the first suppression (revival) time scales linearly with the system size and its scaling ratio is unique for all quenches independent to the initial phase. This is the promised universality of the first suppression (revival) time.

I. INTRODUCTION

The evaluating quantum coherence (QC) is highly substantial for both quantum foundations and quantum technologies [1, 2]. Quantum coherence itself represents an essential feature of quantum states and supports all forms of quantum correlations [3], however, the inevitable interaction of the system with the environment mostly brings incoherency to the input states and evolves a coherence loss [4]. Recently, several precise measures have been introduced to quantify the quantum coherence [5–8], including the $l_1$-norm quantum coherence (Cl$_1$) [5], the relative entropy of coherence (REC) [5], the trace norm quantum coherence (TQC) [5, 9] and the Wigner-Yanase skew (WYSI) information [10]. Among these quantum resource measures, the TQC and the $l_1$-norm quantum coherence are defined through well trace norm, where a closed analytical formula for calculating X-states has been derived invariant under unitary transformations [9, 11–14]. Skew information firstly introduced by Wigner and Yanase in 1963 [15], and it was originally used to represent the information content of mixed states. In the theory of statistical estimation, the statistical idea govern skew information is the Fisher information [16], which is not only a key notion of statistical inference [17] but also plays an important role in informational treatments of physics [18–20]. Nowadays, quantum Fisher information (QFI), as a witness of multipartite entanglement, displays much richer aspects of complex structures of topological states [21]. It has been extensively explored in many different fields such as the calculation of quantum speedup limit time [22]; the study of uncertainty relations [23, 24]; and the properties of quantum phase transition [25, 26]. In particular, the quantum Fisher information prepares a bound to characterize the members of a family of probability distributions. Moreover, when quantum systems are involved, an excellent measurement may be found using tools from quantum estimation theory. This is especially true for a kind of problems that the quantity of interest is not directly available.

The quantum version of the Cramér-Rao inequality has been introduced [18, 27–29] and the lower bound is imposed by QFI [28]. Different features of quantum coherence have been studied, including quantification, dynamic evolution and operational explanation of quantum coherence [7, 30–33]. Some recent works have examined the relationship between quantum coherence and quantum phase transition [24–26], as well as, the performance of the quantum walk version of the Deutsch-Jozsa algorithm [34] and the deterministic quantum computation with one quantum bit (DQC1) algorithm [35, 36]. Moreover, it has been shown that multipartite entanglement which witnessed by QFI can capture a quantum phase transition point [37, 38]. Despite several works on quantum coherence and QFI, the dynamics of quantum coherence and QFI have not yet been studied sufficiently. Therefore, understanding dynamical behaviour of quantum coherence and QFI would be very useful for the description of the nonequilibrium dynamics and universal behavior of quantum many-body systems [39–45].

In this paper we study the dynamical behaviour of the relative entropy of coherence, $l_1$-norm of coherence, and also as measures of quantum coherence, the Wigner-Yanase skew and quantum Fisher information, for a one-dimensional XY-model with time-dependent (step function) couplings, in an external time-dependent (step function) transverse magnetic field. We find that, all of these quantities show suppressions and revivals when the system is quenched to the critical point. We also show that, the first suppression (revival) time scales linearly with the system size. This scaling ratio is independent of the size of quench and the phase of system, where the system is initially prepared in.
II. TIME DEPENDENT XY-MODEL

The Hamiltonian of time-dependent XY-model in a one-dimensional lattice is given by [46–49]

\[
\mathcal{H} = -\frac{N}{2} \left[ J(t) \left[ (1+\gamma) S_i^x S_{i+1}^x + (1-\gamma) S_i^y S_{i+1}^y \right] + h(t) S_i^z \right],
\]

where, \( N \) shows the site’s number, \( \gamma \) is the anisotropy parameter. Here \( S_i^\alpha \) are the spin half operators at the \( i \)th site, which are defined by half of the Pauli matrices as follow

\[
S_i^\alpha = \frac{1}{2} \sigma_i^\alpha; \quad \alpha = \{x, y, z\}.
\]

To study the effect of a time-varying coupling parameter, \( J(t) \), and magnetic field, \( h(t) \), we assume the following expressions

\[
\begin{align*}
J(t) &= J_0 + (J_1 - J_0) \Theta(t); \\
h(t) &= h_0 + (h_1 - h_0) \Theta(t),
\end{align*}
\]

where \( \Theta(t) \) is the Heaviside step function defined by

\[
\Theta(t) = \begin{cases} 
0 & t \leq 0 \\
1 & t > 0
\end{cases}.
\]

In such a case, this model is exactly solvable with the Jordan-Wigner transformation and the magnetization and two-point correlation functions can be calculated analytically [46–50].

In the subsequent calculations, we assume that the system is initially at the thermal equilibrium. In this respect, the reduced two-spin density matrix \( \varrho_{l,m}(t) \) is achieved by

\[
\varrho_{l,m}(t) = \left( \begin{array}{ccc}
\rho_{11} & 0 & 0 \\
0 & \rho_{22} & \rho_{23} \\
0 & \rho_{23} & \rho_{33}
\end{array} \right),
\]

where its matrix elements can be written in terms of one- and two-point correlation functions, which are given by

\[
\begin{align*}
\rho_{11} &= \langle M_l^x \rangle + \langle S_l^x S_m^x \rangle + \frac{1}{4}; \\
\rho_{22} &= \rho_{33} = -\langle S_l^x S_m^x \rangle + \frac{1}{4}; \\
\rho_{23} &= \langle S_l^x S_m^y \rangle + \langle S_l^y S_m^x \rangle; \\
\rho_{14} &= \langle S_l^x S_m^z \rangle - \langle S_l^y S_m^y \rangle; \\
\rho_{44} &= -\langle M_l^x \rangle + \langle S_l^x S_m^z \rangle + \frac{1}{4}.
\end{align*}
\]

with the magnetization in the \( z \)-direction, which is characterized as follow

\[
M^z = \frac{1}{N} \sum_{j=1}^{N} M_j^z = \frac{1}{N} \sum_{j=1}^{N} S_j^z.
\]

Here, the expectation for the average value is defined by

\[
\langle \cdots \rangle = \frac{\text{Tr}[(\cdots)\varrho(t)]}{\text{Tr}[\varrho(t)]},
\]

where the exact analytical form of the magnetization, and two point pin-spin correlation functions are precisely presented in Refs. [46–50].

III. QUANTUM COHERENCE AND QUANTUM FISHER INFORMATION

As mentioned, quantum coherence is a fundamental physical resource in quantum information tasks [51], and revealing quantum coherence is imperative to accomplish the realization of the quantum correlations. It is understood as a key root for physical resources in quantum computation and quantum information processing, and a rigorous theory has been proposed to define an excellent notion for measuring it [5]. In this section we briefly quantify and review the relative entropy of coherence, \( l_1 \)-norm of coherence, Wigner-Yanase-skew information, and the quantum Fisher information.

A. The relative entropy and \( l_1 \)-norm of coherence

The \( l_1 \)-norm of coherence is defined as a sum of the absolute values of all off-diagonal elements in the density matrix, \( \varrho_{l,m} \), using following expression [5]

\[
\text{Cl}_1(\varrho) = \sum_{l \neq m} |\varrho_{l,m}|.
\]

Moreover, the relative entropy of coherence (REC) is defined as

\[
\text{C}_{\text{REC}}(\varrho) = S(\varrho_{\text{diag}}) - S(\varrho),
\]

where, \( \varrho_{\text{diag}} \) is the diagonal part of \( \varrho_{l,m} \), and the function

\[
S(\varrho_{l,m}) = -\text{Tr}[\varrho_{l,m} \log_2 \varrho_{l,m}],
\]

is the von Neumann entropy of the density matrix \( \varrho_{l,m} \). Calculating the \( l_1 \)-norm for a transverse field XY-model is straightforward and results

\[
\text{Cl}_1 = 4 |\langle S_l^x S_m^z \rangle|.
\]

Furthermore, using the relative entropy formula, Eq. (9), we have

\[
\text{C}_{\text{REC}} = \sum_{q=0}^{1} (\xi_q \log \xi_q + \eta_q \log \eta_q - \zeta_q \log \zeta_q) - 2 \varepsilon \log \varepsilon,
\]

(11)

with

\[
\begin{align*}
\xi_q &= \frac{1}{4} - \langle S_l^x S_m^z \rangle + (-1)^q \left( \langle S_l^x S_m^y \rangle + \langle S_l^y S_m^x \rangle \right), \\
\eta_q &= \frac{1}{4} + \langle S_l^x S_m^z \rangle + (-1)^q \sqrt{\langle S_l^x S_m^z \rangle^2 + (\langle S_l^x S_m^y \rangle - \langle S_l^y S_m^x \rangle)^2}, \\
\varepsilon &= \frac{1}{4} - \langle S_l^x S_m^z \rangle.
\end{align*}
\]

B. The Wigner-Yanase-Skew Information

The definition of the Wigner-Yanase-Skew Information which used as a measure of quantum coherence is given
by [10, 15, 24, 52]

\[
I(\varrho, V) = -\frac{1}{2} \text{Tr}[\sqrt{\varrho} V^2],
\]

where the density matrix \(\varrho\) depict a mixed quantum state, \(V\) is an observable, and \([\cdots, \cdots]\) represents the commutator. The quantity \(I(\varrho, V)\) can also be interpreted as a measure of the quantum uncertainty of \(V\) in the state \(\varrho\) instead of the conventional variance. A set of the local spin’s elements \(\{S^\alpha\}\) is an arbitrary and natural choice of observable which constitutes an local orthonormal basis, as

\[
\text{LQC}_\alpha = I(\varrho_{l,m}, S^\alpha \otimes \mathbb{I}_m).
\]

The reduced two-spin density matrix, Eq. (4), facilitates the analytical evaluation of the Wigner-Yanase skew information of the two-spin density matrix. Thus, one can obtain the eigenvalues and their corresponding normalized eigenvectors of the density matrix as

\[
\begin{align*}
p_1 &= \frac{1}{2}(\rho_{11} + \rho_{44} + \sqrt{\rho_{11}^2 + 4|\rho_{14}|^2}), \\
p_2 &= \frac{1}{2}(\rho_{11} + \rho_{44} - \sqrt{\rho_{11}^2 + 4|\rho_{14}|^2}), \\
p_3 &= \frac{1}{2}(\rho_{22} + \rho_{33} + \sqrt{\rho_{22}^2 + 4|\rho_{23}|^2}), \\
p_4 &= \frac{1}{2}(\rho_{22} + \rho_{33} - \sqrt{\rho_{22}^2 + 4|\rho_{23}|^2}),
\end{align*}
\]

and

\[
\begin{align*}
|\phi_1\rangle &= \frac{1}{N_1} \begin{pmatrix} \rho_{14} \\ 0 \\ 0 \\ p_1 - \rho_{11} \end{pmatrix}, \\
|\phi_2\rangle &= \frac{1}{N_2} \begin{pmatrix} \rho_{14} \\ 0 \\ 0 \\ p_2 - \rho_{11} \end{pmatrix}, \\
|\phi_3\rangle &= \frac{1}{N_3} \begin{pmatrix} 0 \\ \rho_{23} \\ p_3 - \rho_{22} \\ 0 \end{pmatrix}, \\
|\phi_4\rangle &= \frac{1}{N_4} \begin{pmatrix} 0 \\ \rho_{23} \\ p_4 - \rho_{22} \\ 0 \end{pmatrix},
\end{align*}
\]

respectively. Here \(N_i\) \((i = 1, 2, 3, 4)\) are the normalization factors defined by

\[
\begin{align*}
N_1 &= \sqrt{\rho_{14}^2 + (p_1 - \rho_{11})^2}, \\
N_2 &= \sqrt{\rho_{14}^2 + (p_2 - \rho_{11})^2}, \\
N_3 &= \sqrt{|\rho_{23}|^2 + (p_3 - \rho_{22})^2}, \\
N_4 &= \sqrt{|\rho_{23}|^2 + (p_4 - \rho_{22})^2}.
\end{align*}
\]

By straightforward calculations, the root of the two-qubit reduced state \(\varrho_{l,m}\) can be obtained by

\[
\sqrt{\varrho_{l,m}} = \begin{pmatrix}
\alpha_e & 0 & 0 & \lambda_e \\
0 & \beta_e & \nu_e & 0 \\
0 & \nu_e^* & \gamma_e & 0 \\
\lambda_e^* & 0 & 0 & \delta_e
\end{pmatrix},
\]

with the following elements

\[
\begin{align*}
\alpha_e &= |\rho_{14}|^2 \left(\frac{\sqrt{N_1^2}}{N_1^2} + \frac{\sqrt{N_2^2}}{N_2^2}\right), \\
\beta_e &= |\rho_{23}|^2 \left(\frac{\sqrt{N_3^2}}{N_3^2} + \frac{\sqrt{N_4^2}}{N_4^2}\right), \\
\gamma_e &= \sqrt{N_3^2} (p_3 - \rho_{22})^2 + \sqrt{N_4^2} (p_4 - \rho_{22})^2, \\
\delta_e &= \sqrt{N_1^2} (p_1 - \rho_{11})^2 + \sqrt{N_2^2} (p_2 - \rho_{11})^2, \\
\lambda_e &= \rho_{14} \left(\frac{\sqrt{N_1^2} (p_1 - \rho_{11})}{N_1^2} + \frac{\sqrt{N_2^2} (p_2 - \rho_{11})}{N_2^2}\right), \\
\nu_e &= \rho_{23} \left(\frac{\sqrt{N_3^2} (p_3 - \rho_{22})}{N_3^2} + \frac{\sqrt{N_4^2} (p_4 - \rho_{22})}{N_4^2}\right).
\end{align*}
\]

For the bipartite system in Eq. (4), it is found that the two-spin local quantum coherence (LQC) can be written as [53]

\[
\begin{align*}
\text{LQC}_x &= 1 - 2(\alpha_e \beta_e + \gamma_e \delta_e) - 4\text{Re}[\lambda_e \nu_e], \\
\text{LQC}_y &= 1 - 2(\alpha_e \beta_e + \gamma_e \delta_e) + 4\text{Re}[\lambda_e \nu_e], \\
\text{LQC}_z &= 1 - \left[\alpha_e^2 + \beta_e^2 + \gamma_e^2 + \delta_e^2 - 2(|\lambda_e|^2 + |\nu_e|^2)\right],
\end{align*}
\]

which quantify the coherence with respect to the first subsystem locally.

C. The Quantum Fisher Information

Estimation theory is an important topic in different areas of physics [18, 27, 38, 54-56]. In general phase estimation perspective, the evolution of a mixed quantum state, given by the density matrix \(\varrho\), under a unitary transformation, can be described as

\[
\varrho_\theta = e^{-iA\theta} \varrho e^{iA\theta},
\]

where \(\theta\) is the phase shift and \(A\) is an operator. The estimation accuracy for \(\theta\) is bounded by the quantum Cramér-Rao inequality [18, 27]:

\[
\Delta \hat{\theta} \geq \frac{1}{\sqrt{\nu \mathcal{F}(\varrho_\theta)}},
\]

where \(\hat{\theta}\) expresses the unbiased estimator for \(\theta\), and \(\nu\) is the number of times the measurement is repeated. Correspondingly, \(\mathcal{F}(\varrho_\theta)\) is the so-called quantum Fisher Information, and it is defined as [18, 27, 55, 56]

\[
\mathcal{F}(\varrho, A) = 2 \sum_{m,n} \frac{(p_m - p_n)^2}{(p_m + p_n)} |\langle m | A | n \rangle|^2,
\]

where \(p_m\) and \(|\phi_m\rangle\) represent the eigenvalues and eigenvectors of the density matrix \(\varrho\), respectively. In which it is used as
a state probe to estimate \( \theta \). Now, following the route provided in Ref [53], the quantum Fisher Information can be written as

\[
\mathcal{F}_Q = \sum_{\mu} \mathcal{F}(\rho, A_{\mu} \otimes I + I \otimes B_{\mu}),
\]

where \( \{A_{\mu}\} \) and \( \{B_{\mu}\} \) are arbitrary and natural complete sets of local orthonormal observables of the two subsystems with respect to \( \rho \). It has been shown that the value of \( \mathcal{F}_Q \) given by Eq. (22) is independent of the choice of local orthonormal bases [53], meaning that it is an inherent quality of the composite system. For a general two-spin system, the local orthonormal observables \( \{A_{\mu}\} \) and \( \{B_{\mu}\} \) can be defined as

\[
\{A_{\mu}\} = \{B_{\mu}\} = \sqrt{2}\{I, S^x, S^y, S^z\},
\]

and finally, for the reduced two-spin density matrix in Eq. (4) the analytical evaluation of the QFI can be evaluated as

\[
\mathcal{F}_Q = \frac{16 \left( \langle S_x^l S_x^{l+r} \rangle - \langle S_y^l S_y^{l+r} \rangle \right)^2}{1 + 4 \langle S_z^l S_z^{l+r} \rangle} + \frac{16}{\left( 1 + 4 \langle S_x^l S_x^{l+r} \rangle \right)^2} \left( 1 + 4 \langle S_y^l S_y^{l+r} \rangle \right)
\]

\[
\times \left[ 3 \langle S_x^l \rangle^2 + 4 \langle S_x^l S_x^{l+r} \rangle^2 - 2 \langle S_x^l S_y^{l+r} \rangle - \langle S_y^l S_y^{l+r} \rangle \right]
\]

\[
+ \left( 1 - 8 \langle S_y^l S_y^{l+r} \rangle \right) \left( \langle S_y^l S_x^{l+r} \rangle + \langle S_y^l S_y^{l+r} \rangle \right)
\]

\[
+ 4 \langle S_x^l S_x^{l+r} \rangle^3 + 4 \langle S_y^l S_y^{l+r} \rangle^3 \right].
\]

\[(24)\]

IV. NUMERICAL RESULTS AND DISCUSSIONS

We now come to present our numerical results. For this purpose, we restrict ourselves to the transverse field Ising model (TFIM) by setting \( J_1 = J_0 = 1 \), and \( \gamma = 1 \). It is well-known that the ground state of the TFIM is characterised by a quantum phase transition that takes place at the critical point \( h_c = J_0 \) [57, 58]. This phase transition is a result of the quantum fluctuations at zero temperature, which destroy the quantum correlations in the ground state. It is determined via the order parameter, \( \langle M^z \rangle \), which differs from a finite value for \( h < h_c \) to zero for \( h \geq h_c \). Moreover, the ground state is ferromagnetic aligned in \( x \)-direction for zero magnetic field and it has a paramagnetic alignment along the field for the limit of large magnetic field. Both cases are minimally entangled since the ground state is a product of individual spin states pointing in the \( z \) (\( x \)-) direction as \( h \to \infty \) (\( h \to 0 \)) [57, 58]. Furthermore, by raising the temperature the entanglement shows a sudden decay near the critical point, although at zero temperature and in a vicinity of critical point remains constant [59].

A. Quench away from the critical point

In Fig. 1, we plot the intensity of the relative entropy of coherence (a), the \( h_1 \)-norm of coherence (b), the quantum Fisher information (c), and local quantum coherence (d-f) versus \( t \) and \( h_1 \). The plots are for \( h_0 = 0.7 \), and at zero temperature. As one can see, for zero \( h_1 \), where the spins are completely aligned in the \( x \)-direction, all quantities (except \( C_{11} \)) show an oscillatory behaviour in time. By introducing an external magnetic field, \( h_1 \), the magnitude of quantities increases as field increases until they reach their maximum value close to \( h_1^M = h_1 \approx 0.5 \). In different circumstances, the maximum values of LQC of the composite system. For a general two-spin system, the local orthonormal observables \( \{A_{\mu}\} \) and \( \{B_{\mu}\} \) can be defined as

\[
\{A_{\mu}\} = \{B_{\mu}\} = \sqrt{2}\{I, S^x, S^y, S^z\},
\]

and finally, for the reduced two-spin density matrix in Eq. (4) the analytical evaluation of the QFI can be evaluated as

\[
\mathcal{F}_Q = \frac{16 \left( \langle S_x^l S_x^{l+r} \rangle - \langle S_y^l S_y^{l+r} \rangle \right)^2}{1 + 4 \langle S_z^l S_z^{l+r} \rangle} + \frac{16}{\left( 1 + 4 \langle S_x^l S_x^{l+r} \rangle \right)^2} \left( 1 + 4 \langle S_y^l S_y^{l+r} \rangle \right)
\]

\[
\times \left[ 3 \langle S_x^l \rangle^2 + 4 \langle S_x^l S_x^{l+r} \rangle^2 - 2 \langle S_x^l S_y^{l+r} \rangle - \langle S_y^l S_y^{l+r} \rangle \right]
\]

\[
+ \left( 1 - 8 \langle S_y^l S_y^{l+r} \rangle \right) \left( \langle S_y^l S_x^{l+r} \rangle + \langle S_y^l S_y^{l+r} \rangle \right)
\]

\[
+ 4 \langle S_x^l S_x^{l+r} \rangle^3 + 4 \langle S_y^l S_y^{l+r} \rangle^3 \right].
\]

\[(24)\]
herence (a), the $l_1$-norm of coherence (b), the quantum Fisher information (c), and local quantum coherence (d-f), versus $t$ and $h_1$. Here we assume $h_0 = 1.5$, where the system initially prepared at paramagnetic phase, $M^z(t, T = 0) \neq 0$. As seen, for $h_1 = 0$, all quantities show an oscillatory behavior in time. Besides, when the external magnetic field is turned on ($h_1 > 0$), the magnitude of all quantities except LQC$_x$ and LQC$_y$, enhances until they reach their maximum value at the equilibrium critical point $h_0^{c\downarrow} = h_1 = h_c$, then reduces by increasing the magnetic field. From these findings one can conclude that dynamical two-spin local $S^x, S^z$ quantum coherence (WYSI), independent the initial state, can positively pick out the critical point while the REC, QFI, and Cl$_1$ fail in this task.

On top of that, there would be a great interest to study the effect of temperature on the critical behavior of many body systems such as the spin systems [59–62]. To show whether the WYSI is able to pinpoint the critical point at finite temperature, we plot the LQC$_x$ and LQC$_z$ in Fig. 3 for different temperatures, namely $T = 1$, and $T = 5$. Although the maximum value of LQC decreases as the temperature increases, the equilibrium phase transition point can still be signalled by the maximum of LQC$_x$ and LQC$_z$ at low temperature. This significant property can be easily applied to determine quantum critical points of the systems which today’s technology makes it virtually impossible to achieve the necessary temperature in which quantum fluctuations are dominated.

### B. Quench to the critical point

The time evolution of REC, Cl$_1$, QFI, and LQC are plotted for a quench to the critical point $h_1 = 1$, for $h_0 = 0.7$ in Fig. 4 for different system sizes. As is clear, in a very short time all quantities change rapidly from the equilibrium state to their average (constant) value, which they oscillate around. More than that, all quantities show suppressions and revivals as deviations from the average value. In order to study the effect of the system size on revival/suppression time, $t_r$, we also plot $t_r(N)$ versus the system size in Fig. 4(f). As seen, the $t_r$ increases linearly by the system size, i.e.

$$t_r(N) = \tau N,$$

where the scaling ratio is obtained as $\tau = 0.2405$. A more detailed analysis shows that $t_r$ and $\tau$ are the same for all quenches and do not depend on the phase of system where initially prepared. This is the promised universality of revival/suppression time, which shows that the size of the quench (different values of $h_0$) and the initial phase of system are unimportant.

We also demonstrate in Fig. 5 the evolution of REC, Cl$_1$, QFI, and LQC for $h_1 = 1.5$ and $h_0 = h_c$, where the system prepared initially at the critical point. Applying the external magnetic field causes a rapidly change in all quantities from the equilibrium state to a constant value, before starting oscillations at the time $t_c(N)$ [See the insets in Figs. 5(a-e)]. In principle, $t_c(N)$ is an instances time under which all curves, correspond to a system larger than size $N$, clearly join together. Examining the details in Fig. 5(f), also shows a linear behavior of $t_c$ versus $N$.

$$t_c(N) = \tau_c N,$$
FIG. 4. (Color online) The evolution of (a) the relative entropy of quantum coherence, (b) the $\ell_1$-norm of quantum coherence (c) the quantum Fisher information $F_Q$, and (d and e) local quantum coherence, for a quench to the critical point $h_1 = h_c$, for $h_0 = 0.7$ at zero temperature and for the different system sizes. (f) shows the linear behaviour of the first suppression-time (revival-time), $t_r(N)$, versus the system size.

FIG. 5. (Color online) (a-e) The same plots as Fig. 4(a-e) but for the case that the system is at the critical point $h_0 = h_c$, and quenched to $h_1 = 1.5$. All plots shows again an oscillating behaviour after the time $t_c$, which scales linearly versus the system size shown in (f).
and interestingly we find a similar scaling value as revival/suppression time, namely $\tau_{\text{c}} = \tau = 0.2405$. Our calculations show that, $t_{\text{c}}$, and $\tau_{\text{c}}$ are the same for all quenches and do not depend on the phase of system where it quenched to. This is the promised universality of $t_{\text{c}}$ which shows that the size of the quench (different values of $h_1$) and the phase of system, where the system is quenched to, are ineffectual.

Finally, we study the dynamics of REC, $C_I$, WYSI and QFI for anisotropic case $\gamma \neq 0$. Our numerical analysis show that our previous findings are correct for anisotropic case. On the other hand, it is worthwhile to mention that, for the case $\gamma < 0$ where $\langle M^y(t, T = 0) \rangle \neq 0$, the critical point is signalled by the maximum of $LQC_y$. Moreover, the numerical simulation shows that $t_{\text{c}}$, $\tau_{\text{c}}$ and their scaling ratios, $\tau$ and $\tau_{\text{c}}$ are independent of the anisotropy parameter.

V. SUMMARY

We have reported the dynamical behaviour of quantum coherence in the one dimensional time-dependent transverse magnetic field XY-model with time-dependent couplings. For this purpose, we investigate the dynamics of relative entropy of coherence, $l_1$-norm of coherence, Wigner-Yanase-skew information, and quantum Fisher information in the system. We show that, the phase-transition point can be signalled by the maximum of Wigner-Yanase-skew information even at low temperature. While relative entropy of coherence, $l_1$-norm of coherence and quantum Fisher information lack such an indicator of criticality in the model. In addition, we find that all of these quantities show suppressions and revivals by quenching the system to the critical point. Further, the first suppression (revival) time scales linearly with system size, and free from the quench size and the initial phase of system, therefore our work highlights the universality in out-of-equilibrium quantum many-body systems. In the future, it will be interesting to extend the current investigation to more general time dependent cases of external magnetic field, such as exponential or periodic functions. Moreover, it is worthwhile to extend the calculation to disorder case.

ACKNOWLEDGMENT

We thank U. Mishra for helpful discussions. A.A. acknowledges financial support from the National Research Foundation (NRF) funded by the Ministry of Science of Korea (Grants: No. 2016K1A4A01922028, No. 2017R1D1A1B03033465, and No. 2019R1H1A2039733).
