Denominators of cluster variables

Aslak Bakke Buan, Bethany R. Marsh and Idun Reiten

Abstract
Associated to any acyclic cluster algebra is a corresponding triangulated category known as the
cluster category. It is known that there is a one-to-one correspondence between cluster variables
in the cluster algebra and exceptional indecomposable objects in the cluster category, inducing
a correspondence between clusters and cluster-tilting objects.

Fix a cluster-tilting object $T$ and a corresponding initial cluster. By the Laurent phenomenon,
every cluster variable can be written as a Laurent polynomial in the initial cluster. We give
conditions on $T$ that are equivalent to the fact that the denominator in the reduced form for
every cluster variable in the cluster algebra has exponents given by the dimension vector of the
corresponding module over the endomorphism algebra of $T$.

Introduction
Cluster algebras were introduced by Fomin and Zelevinsky [12], and have been influential in
many settings including algebraic combinatorics, Lie theory, Poisson geometry, Teichmüller
theory, total positivity and quiver representations.

The first link to quiver representations and tilting theory for algebras was given in [20].
Cluster categories were defined in [4], giving a categorical model for cluster combinatorics. For
type $A$, an independent approach was given in [8].

A cluster algebra is, in essence, a commutative ring with a distinguished countable family
of generators, called cluster variables. The cluster variables can be grouped into overlapping
sets of equal finite size $n$, called clusters. Any given cluster variable can be uniquely expressed
as a rational function in the elements of a fixed initial cluster. By the Laurent phenomenon,[12, 3.1], these rational functions are actually Laurent polynomials with integer coefficients.

Corresponding to each cluster, there is a quiver $Q$ with $n$ vertices. The cluster algebra is said
to be acyclic [1] if it admits a cluster for which the corresponding quiver $Q$ has no oriented
cycles. In this case there is a corresponding finite-dimensional hereditary algebra, the path
algebra of $kQ$ (for some field $k$) giving rise to a cluster category.

In [7] a surjective map $\alpha$ from the cluster variables of an acyclic cluster algebra to the
exceptional indecomposable objects in the corresponding cluster category was given. In [10] a
map was defined in the opposite direction, and it was shown that this map is a bijection with
$\alpha$ as inverse (see also [3]). Our exposition is made in such a way that it is easy to see where
the fact that $\alpha$ is a bijection is used.

An interesting property of the map $\alpha$ from [7] is the following. Choose a cluster whose
 corresponding quiver is acyclic. If a cluster variable (not from this cluster) is expressed
as a Laurent polynomial in the cluster variables from this cluster, then there is a natural
interpretation of the monomial in the denominator in terms of the composition factors of its
image under $\alpha$ (regarded as a $kQ$-module). This generalized earlier results in this direction
[9, 11, 13, 21].

It is interesting to ask whether, for an arbitrary choice of initial cluster, it is possible to interpret the monomial in the denominator of a cluster variable in terms of the composition factors of the module (over an appropriate cluster-tilted algebra) corresponding to the image of the cluster variable under \( \alpha \). The cluster-tilted algebra involved should be the endomorphism algebra of the cluster-tilting object \( \tau T \) that is obtained by forming the direct sum of the images of the fixed initial cluster under \( \alpha \). We remark that such an interpretation has been found in the Dynkin case in [9, 21].

In this paper we give a precise answer to this question for the general case by giving necessary and sufficient conditions on the cluster-tilting object \( T \) and sufficient conditions on the cluster-tilting object \( \alpha \) of the fixed initial cluster under \( \alpha \). We remark that such an interpretation has been found in the Dynkin case in [9, 21].

We would like to thank Otto Kerner for answering several questions on wild algebras, and especially for assisting us with the proof of Proposition 2.6.

1. Background and main results

Let \( Q \) be a finite connected acyclic quiver and \( k \) be an algebraically closed field. Let \( H = kQ \) be the corresponding (finite-dimensional) path algebra and \( D^b(kQ) \) be the bounded derived category of finite-dimensional \( kQ \)-modules. The bounded derived category has autoequivalences \( \tau \) (the Auslander–Reiten translate) and \( [1] \) (the shift). Let \( \mathcal{C} = D^b(kQ)/\tau^{-1}[1] \) be the corresponding cluster category. We shall regard modules over \( kQ \) as objects of \( \mathcal{C} \) (via the natural embedding of the module category over \( kQ \) in \( D^b(kQ) \)). For \( i \), a vertex of \( Q \), let \( P_i \) denote the corresponding indecomposable projective \( kQ \)-module.

Let \( \mathcal{A} = \mathcal{A}(Q) \subseteq \mathbb{F} = k(x_1, x_2, \ldots, x_n) \) be the (acyclic, coefficient-free) cluster algebra defined using the initial seed \((\mathbf{x}, Q)\), where \( \mathbf{x} \) is the transcendence basis \( \{x_1, x_2, \ldots, x_n\} \) of \( \mathbb{F} \).

For an object \( M \) of \( \mathcal{C} \), let \( c_M = \prod_{i=1}^{\dim \text{Hom}_k(F, M)} x_i \). For a polynomial \( f = f(z_1, z_2, \ldots, z_n) \), we say that \( f \) satisfies the positivity condition if \( f(c_i) > 0 \), where \( c_i = (1, 1, 0, 1, \ldots, 1) \) (with a 0 in the \( i \)th position) for \( i = 1, 2, \ldots, n \). This condition was crucial in the investigations in [7], and also plays an essential role here.

We first recall the following results.

**Theorem 1.1** [7, 2.2]. Every cluster variable of \( \mathcal{A} \) is either of the form \( f/c_M \) (for some exceptional \( kQ \)-module \( M \)) or of the form \( fx_i \) for some \( i \), where, in either case, \( f = f(x_1, x_2, \ldots, x_n) \) satisfies the positivity condition. Every indecomposable exceptional \( kQ \)-module arises in this way, and if \( M \) and \( M' \) are two such modules satisfying \( c_M = c_{M'} \), then \( M \simeq M' \).

A map \( \alpha \) is then defined from cluster variables of \( \mathcal{A} \) to (isomorphism classes of) exceptional indecomposable objects of \( \mathcal{C} \) in the following way. If \( f/c_M \) is a cluster variable for some exceptional indecomposable \( kQ \)-module \( M \), then \( \alpha(f/c_M) = M \). If \( fx_i \) is a cluster variable then \( \alpha(fx_i) = P_i[1] \).

Recall that a tilting seed for \( \mathcal{A} \) is a pair \((T, Q')\), where \( T \) is a cluster-tilting object of \( \mathcal{C} \) and \( Q' \) is the quiver of \( \text{End}_\mathcal{C}(T)\text{opp} \).
Theorem 1.2 [7, 2.3]. The map
\[ \alpha : \{ \text{cluster variables of } \mathcal{A}(Q) \} \to \{ \text{indecomposable exceptional objects in } \mathcal{C} \} \]
is surjective. It induces a surjective map \( \bar{\alpha} : \{ \text{clusters} \} \to \{ \text{cluster-tilting objects} \} \), and a surjective map \( \bar{\alpha} : \{ \text{seeds} \} \to \{ \text{tilting seeds} \} \), preserving quivers.

We also have the following result of [11]; see also [3].

Theorem 1.3. There is a bijection \( \beta : M \to X_M \) from indecomposable exceptional objects of \( \mathcal{C} \) to cluster variables of \( \mathcal{A} \) such that, for any indecomposable exceptional \( kQ \)-module \( M \), we have \( X_M = f/c_M \) as an irreducible fraction of integral polynomials in the \( x_i \).

In particular, \( \alpha \) is an inverse of \( \beta \) and, for the cluster variables \( fx_i \) considered in Theorem 1.1, we can only have \( f = 1 \).

Let \( \Gamma \) be a quiver mutation-equivalent to \( Q \). Then there is a seed \((y, \Gamma)\) of \( \mathcal{A} \), where \( y = \{y_1, y_2, \ldots, y_n\} \) is a transcendence basis of \( F \). For \( i = 1, 2, \ldots, n \), let \( T_i = \tau^{-1} \alpha(y_i) \), so that we have \( \alpha(y_i) = \tau T_i \). It follows from Theorem 1.2 that \( \prod_{i=1}^n \tau T_i \) is a cluster-tilting object in \( \mathcal{C} \) and that the quiver of its endomorphism algebra in \( \mathcal{C} \) is \( \Gamma \). Hence the same holds for \( T = \prod_{i=1}^n T_i \).

We can ask whether results analogous to the above hold for cluster variables when they are expressed in terms of the initial cluster \( \{y_1, y_2, \ldots, y_n\} \). For an object \( M \) in \( \mathcal{C} \), let \( t_M = \prod_{i=1}^n y_i^{\dim \text{Hom}_\mathcal{C}(T_i, M)} \).

An interesting open question is whether \( t_M \) (or, equivalently, the dimensions of the spaces \( \text{Hom}_\mathcal{C}(T_i, M) \) for \( i = 1, 2, \ldots, n \)) determines \( M \) uniquely. This is true if \( T = kQ \) is the direct sum of the non-isomorphic indecomposable projective modules, but is not known in general. In particular, this means that an approach following [7] exactly in this more general context is not possible.

Definition 1.4. Let \( x \) be a cluster variable of \( \mathcal{A} \). We say that \( x \) expressed in terms of the cluster \( y \) has a \( T \)-denominator if either of the following two conditions hold.

(a) We have that \( \alpha(x) = M \) for some exceptional indecomposable object \( M \) of \( \mathcal{C} \) that is not isomorphic to \( \tau T_i \) for any \( i \), and \( x = f/t_M \).

(b) We have that \( \alpha(x) = \tau T_i \) for some \( i \), and \( x = fy_i \).

In either case, \( f \) is a polynomial in the \( y_i \) satisfying the positivity condition.

Our first main result is the following.

Theorem 1.5. Let \( Q \) be a finite quiver with no oriented cycles, and let \( k \) be an algebraically closed field. Let \( \mathcal{C} \) be the cluster category associated to \( kQ \), and let \( T = \prod_{i=1}^n T_i \) be a cluster-tilting object in \( \mathcal{C} \). Let \( \mathcal{A} = \mathcal{A}(Q) \) be the cluster algebra associated to \( Q \). Then the following hold:

(a) if no indecomposable direct summand of \( T \) is regular, then every cluster variable of \( \mathcal{A} \) has a \( T \)-denominator;

(b) if every cluster variable of \( \mathcal{A} \) has a \( T \)-denominator, then \( \text{End}_\mathcal{C}(T_i) \simeq k \) for all \( i \).

We note that, as in Theorem 1.1, the bijectivity of \( \alpha \) can be used to show that, in case (b) of Definition 1.4, only \( f = 1 \) occurs. The proof of Theorem 1.5 will be completed at the end of Section 4. In the special case where \( kQ \) is a tame algebra, we have the following.
Theorem 1.6. Suppose that we are in the situation of Theorem 1.5 and that, in addition, $kQ$ is a tame algebra. Then the following are equivalent.
(a) Every cluster variable of $A$ has a $T$-denominator.
(b) No regular summand $T_i$ of quasilength $r-1$ lies in a tube of rank $r$.
(c) For all $i$, $\text{End}_C(T_i) \simeq k$.

The proof of Theorem 1.6 will be completed at the end of Section 6. As a consequence of our main results, we have the following corollary in the general case.

Corollary 1.7. Let $Q$ be a finite quiver with no oriented cycles. Let $C$ be the cluster category associated to $kQ$. Let $A = A(Q)$ be the cluster algebra associated to $Q$. Then every cluster variable of $A$ has a $T$-denominator for every cluster-tilting object $T$ if and only if $Q$ is Dynkin or has exactly two vertices.

The proof of Corollary 1.7 will be completed at the end of Section 4.

2. Conditions on a cluster-tilting object

In this section we consider certain conditions on a cluster-tilting object that are equivalent to all cluster variables in $A$ having a $T$-denominator. Fix an almost complete (basic) cluster-tilting object $T'$ in $C$. Let $M$ and $M^\ast$ be the two complements of $T'$, so that $T' = T' \bigsqcup M$ and $T'' = T' \bigsqcup M^\ast$ are cluster-tilting objects (see [4, §6]). Let
\begin{align}
M^\ast & \xrightarrow{f} B \xrightarrow{g} M \xrightarrow{h}, \\
M & \xrightarrow{f'} B' \xrightarrow{g'} M^\ast \xrightarrow{h'}
\end{align}

be the exchange triangles corresponding to $M$ and $M^\ast$ (see [4, §6]), so that $B \to M$ is a minimal right $\text{add}(T')$-approximation of $M$ in $C$ and $B' \to M^\ast$ is a minimal right $\text{add}(T')$-approximation of $M^\ast$ in $C$. The following definition appears to be important for understanding the link between representation theory and denominators of cluster variables.

Definition 2.1. Let $N$ be an exceptional indecomposable object of $C$. We say that $N$ is compatible with an exchange pair $(M, M^\ast)$ if the following holds whenever $M \not\simeq \tau N \not\simeq M^\ast$:
\[
\dim \text{Hom}_C(N, M) + \dim \text{Hom}_C(N, M^\ast) = \max(\dim \text{Hom}_C(N, B), \dim \text{Hom}_C(N, B')) + 1.
\]

If $N$ is compatible with every exchange pair $(M, M^\ast)$ in $C$ then we call $N$ exchange compatible.

We will investigate when this condition is satisfied. Note that the case when $M \simeq \tau N$ or $M^\ast \simeq \tau N$ is covered by the following.

Lemma 2.2. Let $N$ be an exceptional indecomposable object of $C$ and suppose that $M \simeq \tau N$ or $M^\ast \simeq \tau N$. Then we have that
\[
\dim \text{Hom}_C(N, M) + \dim \text{Hom}_C(N, M^\ast) = \max(\dim \text{Hom}_C(N, B), \dim \text{Hom}_C(N, B')) + 1.
\]
Proposition 2.3. Suppose that neither $M$ nor $M^*$ is isomorphic to $\tau N$. Then the following are equivalent.

(a) We have that
\[
\dim \text{Hom}_C(N, M) + \dim \text{Hom}_C(N, M^*) = \max(\dim \text{Hom}_C(N, B), \dim \text{Hom}_C(N, B')).
\]

(b) Either the sequence
\[
0 \to \text{Hom}_C(N, M^*) \to \text{Hom}_C(N, B) \to \text{Hom}_C(N, M) \to 0
\]

is exact, or the sequence
\[
0 \to \text{Hom}_C(N, M) \to \text{Hom}_C(N, B') \to \text{Hom}_C(N, M^*) \to 0
\]

is exact.

Proof. Consider the (not necessarily exact) sequence
\[
\text{Hom}_C(N, M^*) \to \text{Hom}_C(N, B) \to \text{Hom}_C(N, M) \to \text{Hom}_C(N, B') \to \text{Hom}_C(N, M^*).
\]
By exactness at the second term, we have that $\text{Ker } b = \text{Im } a$. Let $r = \dim \text{Hom}_C(N, M^*)$, $s = \dim \text{Hom}_C(N, B)$, $t = \dim \text{Hom}_C(N, M)$ and $u = \dim \text{Hom}_C(N, B')$. Then we have that $s = \dim \text{Ker } b + \dim \text{Im } b = \dim \text{Im } a + \dim \text{Im } b \leq r + t$. Similarly, by exactness at the fourth term, we have that $u \leq t + r$. Then the sequence (3) is exact if and only if $b$ is surjective and $a$ is injective, if and only if $\dim \text{Im } b = t$ and $\dim \text{Im } a = r$. By the above argument that $s \leq r + t$, we see that this is true if and only if $s = r + t$. Similarly, the sequence (4) is exact if and only if $u = r + t$. Hence (b) holds for $N$ if and only if $s = r + t$ or $u = r + t$. Since in any case $s \leq r + t$ and $u \leq r + t$, we see that (b) holds if and only if $r + t = \max(s, u)$ as required.

Let $X$ and $Y$ be indecomposable objects of $C$. We can always represent such objects by indecomposable $kQ$-modules or objects of the form $P_i[1]$ for some $i$. We also call these $X$ and $Y$, by an abuse of notation. By [4, 1.5], $\text{Hom}_C(X, Y) = \bigoplus \text{Hom}_D(X, Y)$. We call an element of $\text{Hom}_H(X, Y)$ an $H$-map from $X$ to $Y$, and an element of $\text{Hom}_D(X, Y)$ an $F$-map from $X$ to $Y$. We note that the composition of two $H$-maps is an $H$-map and the composition of two $F$-maps is zero. The composition of an $H$-map and an $F$-map is an $F$-map.

Proposition 2.4. If $N$ is an indecomposable exceptional object with $\text{End}_C(N) \not\iso k$, then there is an indecomposable exceptional object $N^*$ such that $(N, N^*)$ is an exchange pair and $N$ is not compatible with this exchange pair.

Proof. By the above, we must have $\text{Hom}_D(N, FN) \not= 0$ since $\text{Hom}_H(N, N) \iso k$. But
\[
\text{Hom}_D(N, FN) = \text{Hom}_D(N, \tau^{-1} N[1]) \iso \text{Ext}_D^1(N, \tau^{-1} N) \iso D \text{Hom}_D(N, \tau^2 N),
\]
from which it follows that \( N \) must be regular and, in particular, \( \text{Hom}_H(N, H) = 0 \). Let \( E \) be the Bongartz complement of \( N \), as defined in [2]. Then \( N \bigoplus E \) is a tilting module. Since \( \text{Hom}_H(N, H) = 0 \), we have, in addition, that \( \text{Hom}_H(N, E) = 0 \), by [16, 6.4].

Now consider \( N \bigoplus E \) as a cluster-tilting object in \( C \), and consider the exchange triangles \( N \to B' \to N^* \) and \( N^* \to B \to N \), where \( B \) and \( B' \) are in \( 
 \text{add} \, E \).

Then the map \( N \to B' \) is a sum of \( F \)-maps. Since, by assumption, \( \text{End}_C(N) \neq k \), we have a non-zero \( F \)-map \( N \to N \). The composition \( N \to N \to B' \) is zero, as the composition of \( F \)-maps is zero. So \( \text{Hom}_C(N, ) \) applied to \( N \to B' \to N^* \) does not give a short exact sequence.

It is clear that \( \text{Hom}_C(N, ) \) applied to \( N^* \to B \to N \) does not give a short exact sequence since the identity map \( N \to N \) does not factor through \( B \to N \).

We claim that \( N \) is not compatible with \((N, N^*)\). We have that \( \text{Ext}_H^1(N, \tau N) \simeq D\text{Hom}_C(N, N) \neq k \), so \((N, \tau N)\) is not an exchange pair, by [4, 7.5]. It follows that \( N^* \neq \tau N \).

We also have that \( N \neq \tau N \) since \( N \) is exceptional. So the proof is completed by combining the above with Proposition 2.3.

We have the following immediate consequence.

**Corollary 2.5.** If \( N \) is an exchange compatible object of \( C \), then \( \text{End}_C(N) \simeq k \).

The following is a description of the indecomposable exceptional modules \( N \) with \( \text{End}_C(N) \neq k \). We know that such \( N \) must be regular. In the tame case the indecomposable exceptional modules in a tube of rank \( t \) are those of quasilength at most \( t - 1 \). In the wild case, for a component of the AR-quiver, there is some \( r \) with \( 0 \leq r \leq n - 2 \), where \( n \) is the number of simple modules, such that \( N \) is exceptional if and only if \( N \) has quasilength at most \( r \).

Let \( X \) be an indecomposable regular module. Then we denote by \( \Delta_X \) the wing of \( X \), as defined in [22, 3.3].

The proof of the next result, which is based on the proof of [18, 1.6; 19, 9.5], was pointed out to us by Kerner.

**Proposition 2.6.** Assume that \( H \) is hereditary of infinite type, and that \( N \) is an indecomposable exceptional regular \( H \)-module. Then \( \text{End}_C(N) \neq k \) if and only if \( N \) has maximal quasilength amongst the indecomposable exceptional modules in its component.

**Proof.** Let \( N \) be an indecomposable exceptional regular \( H \)-module of quasilength \( t \), and let \( N' \) be indecomposable with an irreducible epimorphism \( N' \to N \). Then \( \text{End}_C(N) \neq k \) if and only if \( \text{Hom}_H(N, \tau^2 N) \neq 0 \), and \( N' \) is exceptional if and only if \( \text{Hom}_H(N', \tau N') \simeq \text{Ext}_H^1(N', N) = 0 \), if and only if \( N \) does not have maximal quasilength amongst the indecomposable exceptional modules in its component (note that all indecomposable modules in a \( \tau \)-orbit of an AR-component of a hereditary algebra are always either all exceptional or all not exceptional).

Consider the exact sequences \( 0 \to A \to N' \to N \to 0 \) and \( 0 \to \tau^2 N \to \tau N' \to B \to 0 \). Since \( N' \to N \) is an epimorphism and \( \tau^2 N \to \tau N' \) is a monomorphism (the latter following from the structure of the component containing \( N \) [19, §5]), it follows that \( \text{Hom}_H(N, \tau^2 N) \neq 0 \) implies that \( \text{Hom}_H(N', \tau N') \neq 0 \).

Assume conversely that there is a non-zero map \( f : N' \to \tau N' \). Since the wing \( \Delta_{N'} \), determined by \( \tau N' \) is standard [19], we have that \( \text{Hom}(A, \tau N') = 0 \) (see Figure 1). Hence the composition of the map \( A \to N' \) with \( N \to \tau N' \) is zero. It follows that the map \( N' \to \tau N' \) factors through \( N \) and therefore that there is a non-zero map \( f' : N \to \tau N' \). Similarly, considering the wing \( \Delta_{N'} \), we see that \( \text{Hom}(N, B) = 0 \). Hence the composition of \( f' \) with
the map $\tau N' \to B$ is zero, and $f'$ factors through $\tau^2 N$ and therefore there is a non-zero map $N \to \tau^2 N$. Hence we see that $\text{End}_C(N) \not\cong k$ if and only if $N$ is exceptional of maximal quasilength.

\textbf{Remark 2.7.} The proof in the tame case can be made even shorter.

We note the following consequence of Corollary 2.5 and Proposition 2.6.

\textbf{Corollary 2.8.} Assume that $H$ is of infinite type. If $N$ is indecomposable regular and has maximal quasilength amongst the indecomposable exceptional modules in its component, then $N$ is not exchange compatible.

\section{Expressions for cluster variables}

In this section we show that, for a given cluster-tilting object $T$ in the cluster category of $kQ$, all indecomposable direct summands $T_j$ of $T$ are exchange compatible if and only if all cluster variables in $A(Q)$ have $T$-denominators.

Let $(x', Q')$ be a seed, with $x' = \{x'_1, \ldots, x'_n\}$, and assume that each $x'_i$ has a $T$-denominator. Let $T'_i = \alpha(x'_i)$ for $i = 1, 2, \ldots, n$, and set $T' = \prod_{j=1}^{n} T'_j$. By Theorem 1.2, we have that $T'$ is a cluster-tilting object in $C$ and that $Q'$ is the quiver of $\text{End}_C(T')^{\text{op}}$.

Mutating $(x', Q')$ at $x'_k$, we obtain a new cluster variable $(x'_k)^{*}$. Let $\overline{T'} = \coprod_{j \neq k} T'_j$. Let $(T'_k)^{*}$ be the unique indecomposable object in $C$ with $(T'_k)^{*} \not\cong T'_k$ such that $\overline{T'} \coprod (T'_k)^{*}$ is a cluster-tilting object.

\textbf{Proposition 3.1.} With the above notation and assumptions, the cluster variable $(x'_k)^{*}$ has a $T$-denominator if and only if each summand $T_i$ of $T$ is compatible with the exchange pair $(T'_k, (T'_k)^{*})$.

\textbf{Proof.} We consider the exchange triangles corresponding to the almost complete cluster-tilting object $\overline{T'}$ in $C$ (see triangles (1) and (2)). For an indecomposable direct summand $A$ of $T'$, we denote the corresponding cluster variable in $x'$ by $x_A$. Note that all summands of $B$ and $B'$ are also summands of $\overline{T'}$. We therefore have, by assumption, that, for any summand $A$ of $B$ or $B'$ (or $A = T'_k$), either $A \not\cong \tau T_i$ for any $i$, and $x_A = f_A/t_A$, or $A \cong \tau T_i$ for some $i$, and $x_A = f_A y_i$, where, in either case, $f_A$ is a polynomial satisfying the positivity condition.

We also define $M = T'_k$ and $M^{*} = (T'_k)^{*}$. We note that, by [7, 3.1], $\alpha((x'_k)^{*}) = M^{*}$.

If $A_1, A_2, \ldots, A_t$ are summands of $T'$, then we write

$$x_{A_1} \coprod x_{A_2} \coprod \ldots \coprod x_{A_t} = x_{A_1} x_{A_2} \ldots x_{A_t}.$$
Therefore \( m \) is a monomial, \((m_1)\) is a Laurent polynomial in \( y_1, y_2, \ldots, y_n \) by the Laurent phenomenon \([12, 3.1]\), and \( t_M \) is a monomial, \((f_B y_{B_1} + f_{B'} m' y_{B_1'})/f_M\) is also a Laurent polynomial. Since it is

\[ f_{A_1} \prod A_2 \cdots \prod A_i = f_{A_1} f_{A_2} \cdots f_{A_i}. \]

We also write

\[ y_{T_{i_1}} \prod y_{T_{i_2}} \cdots y_{T_{i_t}} = y_{i_1} y_{i_2} \cdots y_{i_t} \]

for any \( i_1, i_2, \ldots, i_t \in \{1, 2, \ldots, n\}. \)

We have \([6]\) that

\[ x_M(x_M)^* = x_B + x_{B'}. \]  

(5)

The argument now falls into different cases.

**Case I:** Suppose first that neither \( M \) nor \( M^* \) is isomorphic to \( \tau T_i \) for any \( i \). Write \( B = B_0 \prod B_1 \), where \( B_1 \) is the direct sum of all indecomposable summands of \( B \) that are of the form \( \tau T_i \) for some \( i \). Similarly, write \( B' = B'_0 \prod B'_1 \), where \( B'_1 \) is the direct sum of all indecomposable summands of \( B' \) that are of the form \( \tau T_i \) for some \( i \). Then, by assumption, \( x_B = f_B y_{B_1}/t_{B_0} \).

Similarly, \( x_{B'} = f_{B'} y_{B'_1}/t_{B'_0} \).

Let \( m = \text{lcm}(t_{B_0}, t_{B'_0})/t_{B_0} \) and \( m' = \text{lcm}(t_{B_0}, t_{B'_0})/t_{B'_0} \). We have

\[ (x_M)^* = \frac{f_B y_{B_1}/t_{B_0} + f_{B'} y_{B'_1}/t_{B'_0}}{f_M/t_M} = \frac{f_B m y_{B_1} + f_{B'} m' y_{B'_1}}{\text{lcm}(t_{B_0}, t_{B'_0})f_M/t_M} = \frac{(f_B m y_{B_1} + f_{B'} m' y_{B'_1})/f_M}{\text{lcm}(t_B, t_{B'})/t_M}, \]

noting that \( t_B = t_{B_0} \) since \( \text{Hom}_C(T_i, \tau T_j) = 0 \) for all \( i \) and \( j \), and similarly \( t_{B'} = t_{B'_0} \).

Assume now that each of the \( T_i \) is compatible with \((M, M^*)\), so that we have

\[ t_M t_{M^*} = \prod y_i^{\text{dim Hom}_C(T_i, M) + \text{dim Hom}_C(T_i, M^*)} = \prod y_i^{\max(\text{dim Hom}_C(T_i, B), \text{dim Hom}_C(T_i, B'))} = \text{lcm}(t_B, t_{B'}). \]

Hence

\[ (x_M)^* = \frac{(f_B m y_{B_1} + f_{B'} m' y_{B'_1})/f_M}{t_{M^*}}. \]

(6)

By definition of least common multiple, \( m \) and \( m' \) are coprime. Since \( B \) and \( B' \) have no common factors \([6, 6.1]\), \( y_{B_1} \) and \( y_{B'_1} \) are coprime. Suppose that \( m \) and \( y_{B'_1} \) had a common factor \( y_i \). Then there would be a summand \( X \) of \( B'_0 \) such that \( \text{Hom}_C(T_i, X) \neq 0 \), and \( \tau T_i \) was a summand of \( B' \). But then

\[ \text{Ext}_1^C(X, \tau T_i) \simeq D \text{Hom}_C(\tau T_i, \tau X) \simeq D \text{Hom}_C(T_i, X) \neq 0, \]

contradicting the fact that \( B' \) is the direct sum of summands of a cluster-tilting object. Therefore \( m \) and \( y_{B'_1} \) are coprime, and similarly \( m' \) and \( y_{B'_1} \) are coprime. It follows that \( m y_{B_1} \) and \( m' y_{B'_1} \) are coprime.

Let \( i \in \{1, 2, \ldots, n\} \). It follows from our assumptions that \( f_B(e_i) > 0 \) and \( f_{B'}(e_i) > 0 \). It is clear that \((m y_{B_1})(e_i) > 0 \) and \((m' y_{B'_1})(e_i) > 0 \). Since \( m y_{B_1} \) and \( m' y_{B'_1} \) are coprime, these two numbers cannot be simultaneously zero, so \((f_B m y_{B_1} + f_{B'} m' y_{B'_1})(e_i) > 0 \). It follows that \( f_B m y_{B_1} + f_{B'} m' y_{B'_1} \) satisfies the positivity condition. By assumption, \( f_M \) also satisfies the positivity condition.

Since \((x_M)^*\) is a Laurent polynomial in \( y_1, y_2, \ldots, y_n \) by the Laurent phenomenon \([12, 3.1]\), and \( t_{M^*} \) is a monomial, \((f_B m y_{B_1} + f_{B'} m' y_{B'_1})/f_M\) is also a Laurent polynomial. Since it is
defined at \( e_i \) for all \( i \), it must be a polynomial. By the above, it satisfies the positivity condition. It follows that \((x_M)^*\) has a \( T^*\)-denominator.

Now assume that at least one summand of \( T \) is not compatible with \((M, M^*)\). Then \( t_M t_{M^*} = c \frac{\text{lcm}(t_B, t_{B'})}{c} \) for some non-trivial Laurent monomial \( c \). We then obtain that

\[
(x_M)^* = \frac{(f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M}{\text{lcm}(t_B, t_{B'}) / t_M} = \frac{c(f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M}{t_{M^*}},
\]

where, as before, \((f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M\) satisfies the positivity condition. Since \((x_M)^*\) is a Laurent polynomial, \( c \) is a Laurent monomial and \( t_{M^*} \) is a monomial, \((f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M\) is a Laurent polynomial. Since it satisfies the positivity condition, it is defined at \( e_i \) and hence is a polynomial. It also follows from the positivity condition that no \( y_i \) divides \((f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M\), and thus if \( c \) contains any \( y_i \) with a negative exponent then \( c(f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M\) is not a polynomial. On the other hand, if \( c \) contains any \( y_i \) with a positive exponent then \( c(f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M\) evaluated at \( e_i \) will be zero, and we see that it does not satisfy the positivity condition. But one or the other must occur since \( c \) is non-trivial. Thus, in either case, we see that \((x_M)^*\) does not have a \( T\)-denominator.

**Case II:** Next, suppose that \( M \simeq \tau_{T_i} \) for some \( i \). Since \( \text{Ext}_1^C(T_r, T_s) = 0 \) for all \( r \) and \( s \), we cannot have \( M^* \simeq \tau_{T_j} \) for any \( j \) (as \( \text{Ext}_1^C(M, M^*) \neq 0 \)). Assume that the \( T_j \) are all compatible with the exchange pair \((M, M^*)\). Then we have \( t_{M^*} = y_i \frac{\text{lcm}(t_B, t_{B'})}{c} \), noting that \( t_M = 1 \). Here we use, in particular, that

\[
\dim \text{Hom}_C(N, M) + \dim \text{Hom}_C(N, M^*) = \max(\dim \text{Hom}_C(N, B), \dim \text{Hom}_C(N, B')) + 1
\]

holds for \( N = T_i \), by Lemma 2.2. As in the above case, we have \( x_M(x_M)^* = x_B + x_{B'} \). The same analysis, together with the fact that \( x_M = f_M y_i \) for some polynomial \( f \) in the \( y_j \) satisfying the positivity condition, gives

\[
(x_M)^* = \frac{(f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M}{\text{lcm}(t_B, t_{B'})/y_i} = \frac{(f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M}{t_{M^*}}.
\]

As above, we see that the numerator is a polynomial that satisfies the positivity condition, and it follows that \((x_M)^*\) has a \( T\)-denominator.

Now assume that at least one summand of \( T \) is not compatible with \((M, M^*)\). Summands \( T_k \neq T_i \) that are not compatible with \((M, M^*)\) will not satisfy \( \dim \text{Hom}_C(N, M) + \dim \text{Hom}_C(N, M^*) = \max(\dim \text{Hom}_C(N, B), \dim \text{Hom}_C(N, B')) \) for \( N = T_k \).

It follows that \( t_{M^*} = c y_i \frac{\text{lcm}(t_B, t_{B'})}{c} \) for some non-trivial Laurent monomial \( c \). Arguing as above, we obtain that

\[
(x_M)^* = \frac{(f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M}{t_{M^*}/c} = \frac{c(f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M}{t_{M^*}}.
\]

As in Case I, \((f_B m y_{B^*} + f_{B'} m' y_{B^*})/f_M\) satisfies the positivity condition, and it follows that the numerator \( c(f_B m y_{B^*} + f_{B'} m' y_{B^*}) \) is either not a polynomial or does not satisfy the positivity condition (see the argument at the end of Case I) and therefore that \((x_M)^*\) does not have a \( T\)-denominator.
Case III: Next, suppose that $M^* \simeq \tau T_i$ for some $i$. Since $\text{Ext}_C^1(T_r, T_s) = 0$ for all $r$ and $s$, we cannot have $M \simeq \tau T_j$ for any $j$ (as $\text{Ext}_C^1(M, M^*) \neq 0$). Assume that the $T_j$ are all exchange compatible with $(M, M^*)$. We have, using Proposition 2.3, that $t_M = y_i \ \text{lcm}(t_B, t_{B'})$, noting that $t_{M^*} = 1$. As in the above case, we have $x_M(x_M)^* = x_B + x_{B'}$. The same analysis gives

$$(x_M)^* = \frac{(f_B m y_B_i + f_{B'} m' y'_{B_i})/f_M}{\text{lcm}(t_B, t_{B'})/t_M}$$

As in Case I, we see that $(f_B m y_B_i + f_{B'} m' y'_{B_i})/f_M$ is a polynomial that satisfies the positivity condition and it follows that $(x_M)^*$ has a $T$-denominator.

Now assume that at least one summand of $T$ is not compatible with $(M, M^*)$. Then, as in Case II, it follows that $t_M = c y_i \ \text{lcm}(t_B, t_{B'})$ for some non-trivial Laurent monomial $c$. Arguing as above, we obtain that

$$(x_M)^* = \frac{(f_B m y_B_i + f_{B'} m' y'_{B_i})/f_M}{\text{lcm}(t_B, t_{B'})/t_M} = c(f_B m y_B_i + f_{B'} m' y'_{B_i})/f_M y_i.$$ 

Since $(x_M)^*$ is a Laurent polynomial and $c$ is a Laurent monomial, $(f_B m y_B_i + f_{B'} m' y'_{B_i})/f_M$ is a Laurent polynomial. As in Case I, it satisfies the positivity condition and therefore is a polynomial. Arguing as at the end of Case I, it follows that $c(f_B m y_B_i + f_{B'} m' y'_{B_i})/f_M$ is either not a polynomial or does not satisfy the positivity condition and therefore that $(x_M)^*$ does not have a $T$-denominator.

**Theorem 3.2.** All indecomposable direct summands $T_j$ of $T$ are exchange compatible if and only if all cluster variables in $A(Q)$ have a $T$-denominator.

**Proof.** We note that $\alpha(y_i) = \tau T_i$ for $i = 1, 2, \ldots, n$ and that the quiver $\Gamma$ of the seed $(y, \Gamma)$ is the quiver of $\text{End}_C(\bigoplus_{i=1}^n \tau T_i)^{op}$ (see the start of Section 1). Suppose first that all indecomposable direct summands $T_j$ of $T$ are exchange compatible. Let $x$ be a cluster variable of $A(Q)$. It follows from Proposition 3.1 by induction on the smallest number of exchanges needed to get from $y$ to a cluster containing $x$ that $x$ has a $T$-denominator.

Suppose that there is an indecomposable direct summand of $T$ that is not exchange compatible. Consider the cluster $z$ of $A(Q)$ that is a minimal distance in the exchange graph from $y$ such that some summand of $T$ is not compatible with an exchange pair $(\alpha(x), \alpha(x^*))$ of objects coming from an exchange pair $(x, x^*)$ of cluster variables with $x \in z$. Arguing as above, we see that the cluster variables in $z$ all have a $T$-denominator. By Proposition 3.1, we see that $x^*$ does not have a $T$-denominator.

The fact that $\alpha$ is a bijection gives us more information, since it follows that $\alpha(x) = \tau T_i$ if and only if $x = y_i$. For the rest of this article, we freely use this fact. We therefore have the following corollary.

**Corollary 3.3.** All indecomposable direct summands $T_j$ of $T$ are exchange compatible if and only if for every cluster variable $x$ of $A(Q)$ we have either of the following.

(a) The object $\alpha(x)$ is not isomorphic to $\tau T_i$ for any $i$, and $x = f/t_{\alpha(x)}$ for some polynomial $f$ in the $y_i$ satisfying the positivity condition.

(b) We have that $\alpha(x) \simeq \tau T_i$ for some $i$ and $x = y_i$. 
Remark 3.4. Recall that the exponent of $y_i$ in $t_M$ is $d_i = \dim \Hom_C(T_i, M)$. It follows from \cite[Theorem A]{5} that $d_i$ is the multiplicity of the simple top of the projective $\Lambda = \End_C(T)^{op}$-module $\Hom_C(T, T_i)$ as a composition factor in $\Hom_C(T, M)$: we have that

$$\Hom_C(T_i, M) \simeq \Hom_{\Lambda}(\Hom_C(T, T_i), \Hom_C(T, M)),$$

using the fact that $\Hom_C(T_i, \tau T) = 0$ (as $T$ is a cluster-tilting object in $C$). Thus $(d_1, d_2, \ldots, d_n)$ is the dimension vector of the $\Lambda$-module $\Hom_C(T, M)$.

4. The preprojective case

In this section, we adopt the notation from Section 3 but assume, in addition, that $N$ is a preprojective module, a preinjective module or the shift of a projective module. Our aim is to show that such modules are exchange compatible.

Proposition 4.1. Suppose that neither $M$ nor $M^*$ is isomorphic to $\tau N$. Then at least one of the following holds (where the maps are induced from triangle (1) or triangle (2), respectively).

(a) The sequence

$$0 \longrightarrow \Hom_C(N, M^*) \longrightarrow \Hom_C(N, B) \longrightarrow \Hom_C(N, M) \longrightarrow 0$$

is exact.

(b) The sequence

$$0 \longrightarrow \Hom_C(N, M) \longrightarrow \Hom_C(N, B') \longrightarrow \Hom_C(N, M^*) \longrightarrow 0$$

is exact.

Proof. Assume first that $N$ is projective.

Case I: Suppose that $M$ and $M^*$ are both modules. By \cite[4, 1.7(d)]{4}, we know that either triangle (1) or triangle (2) arises from a short exact sequence of modules. Suppose first that triangle (1) arises from a short exact sequence

$$0 \longrightarrow M^* \longrightarrow B \longrightarrow M \longrightarrow 0$$

of modules. Applying the exact functor $\Hom_H(N, -)$ to this, we obtain the exact sequence

$$0 \longrightarrow \Hom_H(N, M^*) \longrightarrow \Hom_H(N, B) \longrightarrow \Hom_H(N, M) \longrightarrow 0,$$

noting that $\Ext^1_H(N, M^*) = 0$ as $N$ is projective. Since $\Hom_C(N, X) \simeq \Hom_H(N, X)$ for all modules $X$ (cf. \cite[4, 1.7(d)]{4}), we obtain (a) above. Similarly, if triangle (2) arises from a short exact sequence of modules, we obtain (b) above.

Case II: Suppose that $M = P[1]$ is the shift of a projective indecomposable module $P$. Since $\Ext^1_C(P[1], P'[1]) = 0$ for any projective module $P'$, we must have that $M^*$ is a module. Let $I$ be the indecomposable injective module corresponding to $P$. Since $H$ is the path algebra of an acyclic quiver, either $\Hom_C(N, P) = \Hom_H(N, P) = 0$ or $\Hom_C(N, I) = \Hom_H(N, I) = 0$. If $\Hom_C(N, P) = 0$, then, applying $\Hom_C(N, -)$ to triangle (1), we obtain the exact sequence

$$0 \longrightarrow \Hom_C(N, M^*) \longrightarrow \Hom_C(N, B) \longrightarrow 0,$$

noting that $\Hom_C(N, M) = \Hom_C(N, P[1]) = 0$ as $N$ is projective. We see that (a) follows.
If $\text{Hom}_C(N, I) = 0$, then we note that $M[1] = P[2] \simeq \tau P[1] \simeq I$. So, applying $\text{Hom}_C(N, \ )$ to triangle (2), we obtain the exact sequence

$$0 \rightarrow \text{Hom}_C(N, B') \rightarrow \text{Hom}_C(N, M^*) \rightarrow 0,$$

noting that $\text{Hom}_C(N, M) = \text{Hom}_C(N, P[1]) = 0$, and (b) follows.

The argument in the case when $M^*$ is not a module is similar.

Now assume that $N$ is a preprojective or preinjective module, or $N$ is a shift of a projective. Then $\tau^n N$ is projective for some $n \in \mathbb{Z}$. Since $M \ncong \tau N$, then $\tau^n M \ncong \tau(\tau^n N)$, and similarly for $M^*$. By the above, either (a) or (b) holds for $\tau^n(N)$, so one of

$$0 \rightarrow \text{Hom}_C(\tau^n N, \tau^n M^*) \rightarrow \text{Hom}_C(\tau^n N, \tau^n B') \rightarrow \text{Hom}_C(\tau^n N, \tau^n M) \rightarrow 0$$

or

$$0 \rightarrow \text{Hom}_C(\tau^n N, \tau^n M) \rightarrow \text{Hom}_C(\tau^n N, \tau^n B') \rightarrow \text{Hom}_C(\tau^n N, \tau^n M^*) \rightarrow 0$$

is exact. Hence one of

$$0 \rightarrow \text{Hom}_C(N, M^*) \rightarrow \text{Hom}_C(N, B) \rightarrow \text{Hom}_C(N, M) \rightarrow 0$$

or

$$0 \rightarrow \text{Hom}_C(N, M) \rightarrow \text{Hom}_C(N, B') \rightarrow \text{Hom}_C(N, M^*) \rightarrow 0$$

is exact (since $\tau$ is an autoequivalence of $\mathcal{C}$) and this completes the proof.

**Corollary 4.2.** Each indecomposable preprojective module, preinjective module or shift of an indecomposable projective module is exchange compatible.

**Proof.** This follows from Proposition 4.1.

**Proof of Theorem 1.5.** We observe that Theorem 1.5(a) follows from Corollary 4.2 and Theorem 1.5(b) follows from Corollary 2.5.

**Proof of Corollary 1.7.** If $Q$ is Dynkin, then $kQ$ has no regular modules, and, if $Q$ has only two vertices, then there are no exceptional regular modules. It follows from Theorem 1.5(a) that, in these cases, every cluster variable has a $T$-denominator for every cluster-tilting object $T$. Conversely, suppose that every cluster variable has a $T$-denominator for every cluster-tilting object $T$. We note that any exceptional indecomposable $kQ$-module can be completed to a tilting module and therefore to a cluster-tilting object, by [4, 3.3]. If $Q$ was not Dynkin and had more than two vertices, then $kQ$ would have an indecomposable regular exceptional module $N$ of maximal quasilength amongst the indecomposable exceptional modules in its AR-quiver component (see [23] for the wild case). By Proposition 2.6, we would have $\text{End}_C(N) \ncong k$, a contradiction to Theorem 1.5(b).

#### 5. Criteria for exactness

In this section we shall interpret exchange compatibility further. The results here hold for any finite-dimensional path algebra. They will be used in the tame case in the next section. To ease notation we let $\text{Hom}_{\mathcal{D}}(\ , \ ) = (\ , \ )$ and $\text{Ext}^1_{\mathcal{D}}(\ , \ ) = 1(\ , \ )$ (note that these coincide with the corresponding Hom and Ext$^1$-spaces over $H$ if both objects are $H$-modules). We also let $\text{Hom}_{\mathcal{C}H}(\ , \ ) = (\ , \ )_{\mathcal{C}}$ and $\text{Ext}^1_{\mathcal{C}H}(\ , \ ) = 1(\ , \ )_{\mathcal{C}}$. 
Lemma 5.1. Let $0 \rightarrow M^* \xrightarrow{f} B \xrightarrow{g} M \rightarrow 0$ be an exact exchange sequence of $H$-modules, and let $N$ be an exceptional indecomposable object in $C$.

(a) Then $(N, \_)_C$ gives a right exact sequence if and only if any $H$-map $h : N \rightarrow M$ factors through $g$.

(b) Also, $(N, \_)_C$ gives a left exact sequence if and only if any $H$-map $s : \tau N \rightarrow M$ factors through $g$.

Proof. Applying $(N, \_)_C$ to the exchange sequence, we obtain the following diagram.

\[
\begin{array}{c}
(N, M^*) \rightarrow (N, B) \rightarrow (N, M) \\
\uparrow \quad \uparrow \quad \uparrow \\
1(\tau N, M^*) \rightarrow 1(\tau N, B) \rightarrow 1(\tau N, M)
\end{array}
\]

The map $(N, M^*) \rightarrow (N, B)$ is injective as $(N, \_)$ is left exact, and the fact that the map $1(\tau N, B) \rightarrow 1(\tau N, M)$ is surjective follows from the long exact sequence obtained by applying $(\tau N, \_)$ to the exchange sequence and the fact that $H$ is hereditary. The claim now follows.

Remark 5.2. Given a finite number of indecomposable objects in a cluster category, where each of them is preprojective, preinjective or the shift of a projective, then, by changing the hereditary algebra $H$, if necessary (that is, via a tilt), we can assume that, in fact, all objects are preprojective (or preinjective). We make use of this in what follows.

Lemma 5.3. Let $M \rightarrow B' \rightarrow M^* \rightarrow$ be an exchange triangle, where $M$ is regular and $M^*$ is preprojective. Let $N$ be an indecomposable regular exceptional module.

(a) The functor $(N, \_)_C$ gives a left exact sequence if and only if, for any non-zero $F$-map $N \rightarrow M$, the composition $N \rightarrow M \rightarrow B'$ is non-zero.

(b) Also, $(N, \_)_C$ gives a right exact sequence if and only if, for any non-zero $F$-map $\tau^{-1}N \rightarrow M$, the composition $\tau^{-1}N \rightarrow M \rightarrow B'$ is non-zero.

Proof. (a) One direction is obvious. Assume that, for any non-zero $F$-map $N \rightarrow M$, the composition $N \rightarrow M \rightarrow B'$ is non-zero. Then we need to see that the map $(N, M)_C \rightarrow (N, B')_C$ is injective. Any non-zero map $N \rightarrow M$ in $C$ must have the form $(h, h')$, where $h$ is an $H$-map and $h'$ is an $F$-map, by [4, 1.5]. Suppose, for a contradiction, that its composition with the map from $M$ to $B'$ is zero. Then there is a map $s : N \rightarrow \tau^{-1}M^*$ such that $(h, h') = ts$, where $t : \tau^{-1}M^* \rightarrow M$ (see Figure 2). Since $\tau^{-1}M^*$ is preprojective and $M$ is regular, we have that $(\tau^{-1}M^*, FM) = (\tau^{-1}M^*, \tau^{-1}M[1]) \simeq (M^*, M[1]) \simeq 1(M^*, M) \simeq D(M, \tau M^*) = 0$ since $\tau M^*$ is preprojective. It follows that $t$ is an $H$-map. Similarly, $(N, \tau^{-1}M^*) = 0$ since $N$ is regular and $\tau^{-1}M^*$ is preprojective, so $s$ is an $F$-map. Comparing $H$-maps and $F$-maps, we see that $h = 0$ and $h' = ts$. Hence the $F$-map $h'$ is non-zero, while its composition with the map from $M$ to $B'$ is zero, contradicting the assumption in (a).
(b) There is a long exact sequence
\[(N, M)_C \longrightarrow (N, B')_C \longrightarrow (N, M^*)_C \longrightarrow (N, \tau M)_C \longrightarrow (N, \tau B')_C \longrightarrow (N, \tau M^*)_C.\]
Hence \((N, B')_C \rightarrow (N, M^*)_C\) is an epimorphism if and only if \((N, \tau M)_C \rightarrow (N, \tau B')_C\) is a monomorphism. This clearly holds if and only if \((\tau^{-1} N, M)_C \rightarrow (\tau^{-1} N, B')_C\) is a monomorphism. By (a), this holds if and only if, for any non-zero \(F\)-map \(\tau^{-1} N \rightarrow M\), the composition \(\tau^{-1} N \rightarrow M \rightarrow B'\) is non-zero. 

We have the following direct consequence of Lemmas 5.1 and 5.3.

**Proposition 5.4.** Let \((M, M^*)\) be an exchange pair with \(M\) regular and \(M^*\) preprojective. Let \(0 \rightarrow M^* \rightarrow B \rightarrow M \rightarrow 0\) and \(M \rightarrow B' \rightarrow M^* \rightarrow 0\) be the corresponding exchange sequence and triangle, where \(B = B_1 \coprod M_1\) and \(B' = B'_1 \coprod M'_1\) with \(B_1 \) and \(B'_1\) preprojective and \(M_1\) and \(M'_1\) regular. Let \(N\) be an indecomposable regular exceptional module.

(a) Applying \((N, \_)_C\) to \(0 \rightarrow M^* \rightarrow B_1 \coprod M_1 \rightarrow M \rightarrow 0\) gives a short exact sequence if and only if any \(H\)-map \(N \coprod \tau N \rightarrow M\) factors through \(M_1 \rightarrow M\).

(b) Applying \((N, \_)_C\) to \(M \rightarrow B'_1 \coprod M'_1 \rightarrow M^* \rightarrow 0\) gives a short exact sequence if and only if, for any non-zero \(F\)-map \(N \coprod \tau^{-1} N \rightarrow M\), the composition \(N \coprod \tau^{-1} N \rightarrow M \rightarrow M'_1\) is non-zero.

**Proof.** (a) If \(N \coprod \tau N \rightarrow M\) is an \(H\)-map, then it cannot factor through \(B_1 \rightarrow M\). We apply Lemma 5.1.

(b) Since \(B'_1\) is preprojective, the map \(M \rightarrow B'_1\) is an \(F\)-map. Hence, if \(N \coprod \tau^{-1} N \rightarrow M\) is an \(F\)-map, then the composition \(N \coprod \tau^{-1} N \rightarrow M \rightarrow B'_1\) must be zero. We apply Lemma 5.3.

6. The tame case

In this section we investigate the case in which \(H\) is tame in more detail. In particular, we determine which exceptional regular modules are exchange compatible in this case.

**Lemma 6.1.** Let \(H\) be a tame hereditary algebra and let \((M, M^*)\) be an exchange pair with \(M\) regular and \(M^*\) preprojective. Let \(0 \rightarrow M^* \rightarrow B \rightarrow M \rightarrow 0\) and \(M \rightarrow B' \rightarrow M^* \rightarrow 0\) be the corresponding exchange sequence and triangle, where \(B = B_1 \coprod M_1\) and \(B' = B'_1 \coprod M'_1\) with \(B_1\) and \(B'_1\) preprojective and \(M_1\) and \(M'_1\) regular. Then the maps \(M_1 \rightarrow M\) and \(M \rightarrow M'_1\) are \(H\)-maps.

**Proof.** The first claim obviously holds since the exchange sequence is in \(\text{mod } H\). For the second claim, by Remark 5.2, by replacing \(H\) with \(H'\) via a tilt, we can assume that \(M^*\) is preinjective, and similarly that \(B'_1\) is preinjective. Then the triangle \(M \rightarrow B' \rightarrow M^* \rightarrow 0\) is the image of an exact sequence of \(H'\)-modules \(0 \rightarrow H'.M \rightarrow H'.B' \rightarrow H'.M^* \rightarrow 0\). Then \(M \rightarrow M'_1\) is an \(H'\)-map and consequently also an \(H\)-map.

**Remark 6.2.** Let \(\mathcal{E}\) denote a category that is either the module category of the path algebra \(\Lambda = A_n\) of a quiver of type \(A_n\) with linear orientation, or the abelian category associated with a tube, that is, a connected component of regular modules over some tame hereditary algebra \(\Lambda\). For an indecomposable exceptional object \(M\) in \(\mathcal{E}\), we let \(\Delta_M\) denote the additive subcategory generated by the subfactors of \(M\) inside \(\mathcal{E}\), or equivalently the extension closure of \(\text{Sub } M \cup \text{Fac } M\). The indecomposable objects in \(\Delta_M\) form a full subquiver of the AR-quiver of \(\Lambda\), which is a triangle with \(M\) sitting on the top (see Figure 3).
LEMMA 6.3. Consider the quiver of type $A_t$ with linear orientation, and let $\Lambda$ be its path algebra. Let $B$ be the indecomposable projective and injective $\Lambda$-module. Assume that $B_1 \to B_2 \to \cdots \to B_s \to B \to C_1 \to \cdots \to C_{t-s}$ is a sequence of irreducible maps, where $t > s > 0$. If $T$ is a tilting module over $\Lambda$, then it must contain one of the $B_i$ (for $1 \leq i \leq s$) or $C_j$ (for $1 \leq j \leq t-s$) as an indecomposable direct summand.

Proof. Assume, to the contrary, that $T$ is a tilting module having none of the $B_i$ or $C_j$ as indecomposable direct summands. The object $B$ is necessarily a summand of $T$ since it is projective–injective. Since $B_s$ only has extensions with the proper factors of $B$, at least one such factor must be a summand of $T$. Let $E_j \in \text{Fac} B \cap \text{add}(T/B)$, with length $j$ maximal. Then, by assumption, $j \leq t - (t-s) - 1 = s - 1$.

Let $P_i$ be the indecomposable projective of length $i$, and let $k = t - j - 1$. Then $T/B$ is in $\Delta_{E_j} \cup \Delta_{P_k}$ since, for $k < l < t$, we have that $P_l$ and all factors of $P_l$ that are not in $\Delta_{E_j}$ have non-trivial extensions with $E_j$. Note that $T/B$ has $t - 1$ non-isomorphic indecomposable summands. Clearly, the subcategory $\Delta_{E_j}$ has at most $j$ summands in $T$, so at least $t - 1 - j = k$ summands $T_1, \ldots, T_{l-(j+1)}$ of $T$ are in $\Delta_{P_k}$. Note that $\Delta_{P_k}$ is clearly equivalent to mod $\Lambda_k$, so $T' = T_1 \square \cdots \square T_{l-(j+1)}$ forms a tilting module in this subcategory, and hence $P_k$ is a summand in $T'$. But this is a contradiction since $P_k$ is equal to some $B_i$. We illustrate the situation in Figure 4.

REMARK 6.4. Let $M$ be an indecomposable regular module in a tube $T$ of rank $n$ for a tame hereditary algebra $H$. Assume that $q.\text{l.}(M) = t < n - 1 = \text{rank } T$ (where $q.\text{l.}$ denotes quasilength). Let $\Lambda_t$ be the path algebra of a quiver of type $A_t$ with linear orientation. Then there is a functor $F_t : \mod \Lambda_t \to \Delta_M \subseteq T$ that is clearly fully faithful (from the structure of the tube), exact and dense, and preserves indecomposability.

The following is due to Strauss [24, Corollary 3.7].
LEMMA 6.5. Let \( M \) be an indecomposable exceptional \( H \)-module for algebra tame hereditary \( H \), lying in a tube \( T \) of rank \( n \). Let \( q.1.(M) = t \) (note that necessarily \( t \leq n - 1 \)). Let \( T = T^{\tau} \prod M \) be a tilting \( H \)-module. Then add \( T \cap \Delta_M = \text{add} \overline{T_0} \), where \( T_0 = F_t(T_0) \), for a tilting module \( T_0 \) in mod \( \Lambda_t \).

LEMMA 6.6. Let \( T \) be a tube of rank \( n \geq 3 \). Let \( N \) and \( M \) be indecomposable objects in \( T \) with \( q.1.(N) = j \), where \( 1 \leq j \leq n - 2 \), and \( q.1.(M) = t \), where \( 1 \leq t \leq n - 1 \). Suppose that

\[
X_1 \rightarrow X_2 \rightarrow \cdots \rightarrow X_t = M
\]

is a sequence of irreducible maps with \( X_t = M \) and \( q.1.(X_i) = i \) and that

\[
M = Y_t \rightarrow Y_{t-1} \rightarrow \cdots \rightarrow Y_1
\]

is a sequence of irreducible maps with \( Y_1 = M \) and \( q.1.(Y_i) = i \).

(a) Let \( f \in \text{Hom}_T(N,M) \) and \( g \in \text{Hom}_T(M, \tau^2 N) \) be non-zero maps. Then the number of modules \( X_i \), for \( 1 \leq i < t \), that \( f \) factors through plus the number of modules \( Y_i \), for \( 1 \leq i < t \), that \( g \) factors through is at least \( t \).

(b) Statement (a) holds if we assume instead that \( f \in \text{Hom}_T(\tau N,M) \) or \( g \in \text{Hom}_T(M, \tau N) \) or both.

Proof. (a) Suppose first that \( j \geq t \). Let

\[
N = U_j \rightarrow U_{j-1} \rightarrow \cdots \rightarrow U_1
\]

be a sequence of irreducible maps with \( N = U_j \) and \( q.1.(U_i) = i \) for all \( i \). Then \( U_t = \tau^a(M) \) for some \( a \), where \( 1 \leq a \leq n - 1 \), so \( U_t = X_{t-a} \). From the structure of the tube it follows that \( f \) factors through \( X_{t-a}, X_{t-a+1}, \ldots, X_{t-1} \), a total of \( a \) modules.

Let

\[
V_1 \rightarrow V_2 \rightarrow \cdots \rightarrow V_j = \tau^2 N
\]

be a sequence of irreducible maps with \( V_j = \tau^2 N \) and \( q.1.(V_i) = i \) for all \( i \). Then \( V_t = \tau^{-b}(M) \) for some \( b \), where \( 1 \leq b \leq n - 1 \), so \( V_{t-b} = Y_{t-b} \). From the structure of the tube it follows that \( g \) factors through \( Y_{t-b}, Y_{t-b+1}, \ldots, Y_{t-1} \), a total of \( b \) modules.

Since \( \tau^{n-2}(\tau^2(N)) = N \) and \( q.1.(N) = j \), we have that \( \tau^{n-2}(j-t)(V_t) = U_t \), so \( a + b = n - 2 - (j-t) = (n - 2 - j) + t \geq t \) since we have assumed that \( j \leq n - 2 \); see Figure 5.

The argument in the case where \( j < t \) is similar, and this completes the proof of (a).

For (b) we just need to remark that a non-zero map \( \tau N \rightarrow M \) factors through more of the \( X_i \) than \( f \) does, and that a non-zero map \( M \rightarrow \tau N \) factors through more of the \( Y_i \) than \( g \) does. Therefore (a) holds if \( N \) is replaced by \( \tau N \), or \( \tau^2 N \) is replaced by \( \tau N \), or both. Statement (b) follows.

\[\square\]
Lemma 6.7. Let $H$ be tame and $N$ be indecomposable exceptional in a tube of rank $n \geq 2$, so that $q.1(N) \leq n - 1$. Then $q.1(N) = n - 1$ if and only if $\dim_k \text{End}_\mathcal{C}(N) > 1$. In this case there is a non-zero $F$-map from $N$ to $N$ and $\dim_k \text{End}_\mathcal{C}(N) = 2$.

Proof. It is easy to see that $\text{Hom}_H(N, \tau^2 N) \neq 0$ (and is one-dimensional) if and only if $q.1(N) = n - 1$, using $\tau^2 N = \tau^{-(n-2)} N$. Furthermore, $\text{Hom}_\mathcal{C}(N, N) = \prod \text{Hom}_\mathcal{D}(N, FN)$. We have that $\text{Hom}_\mathcal{D}(N, FN) \simeq \text{Ext}^1_\mathcal{D}(N, \tau^{-1} N)$, and $\text{Ext}^1_\mathcal{D}(N, \tau^{-1} N) \simeq D \text{Hom}_\mathcal{D}(N, \tau^2 N)$.

Lemma 6.8. Let $H$ be tame and $N$ be indecomposable exceptional in a tube of rank $n \geq 2$, with $q.1(N) = j \leq n - 2$. Let $(M, M^*)$ be an exchange pair, where $M$ and $M^*$ are complements of some almost complete cluster-tilting object $T'$. We assume that $M$ is regular. Then we have an exchange sequence $0 \to \tau^2 M \to B \to M \to 0$ and an exchange triangle $M \to \tau^2 M \to \tau M \to 0$. Write $B = B_1 \prod M_1$ and $B' = B'_1 \prod M'_1$, where $M_1$ and $M'_1$ are regular and $B_1$ and $B'_1$ are preprojective. Then at least one of the following holds:

(a) any $H$-map $N \prod \tau N \to M$ factors through $B \to M$;

(b) for any non-zero $F$-map $N \prod \tau^{-1} N \to M$, the composition $N \prod \tau^{-1} N \to M \to M'_1$ is non-zero.

Proof. We can clearly assume that there is some non-zero $H$-map $N \prod \tau N \to M$ and some non-zero $F$-map $N \prod \tau^{-1} N \to M$, and hence there is some non-zero $H$-map $M \to \tau^2 N \prod \tau N$. In particular, $N$ and $M$ are in the same tube. By Lemma 6.5, $T'$ is the direct sum of the image under $F_i$ of a tilting module $T_0$ in mod $\Lambda_i$ and another summand (using the notation of Remark 6.4). Let $\tilde{T}_0 = F_i(T_0)$.

Case I: We first assume that there is a non-zero $H$-map from $N$ to $M$ and a non-zero $H$-map from $M$ to $\tau^2 N$. By Lemma 6.3 combined with Lemma 6.6(a), we see that either some non-zero $H$-map from $N$ to $M$ factors through some indecomposable direct summand of $T'$ or that some non-zero $H$-map $M \to \tau^2 N$ factors through some indecomposable direct summand of $T$.

In the first case, we see that, since $\text{Hom}_H(N, M) \simeq k$, any non-zero $H$-map from $N$ to $M$ factors through $T'$. Since any non-zero $H$-map from $\tau N$ to $M$ must factor through an $H$-map from $N$ to $M$, it follows that any non-zero $H$-map from $N \prod \tau N$ to $M$ must factor through $T'$, and therefore through $B \to M$, and we see that (a) holds.

In the second case, arguing similarly, we see that any non-zero $H$-map from $M$ to $\tau^2 N \prod \tau N$ factors through the $H$-map component of $M \to \tau^2 M$ (noting that an $H$-map between two modules cannot factor through an $F$-map). It follows that the map from $\text{Hom}_\mathcal{D}(B', \tau^2 N \prod \tau N)$ to $\text{Hom}_\mathcal{D}(M, \tau^2 N \prod \tau N)$ given by composition with the $H$-map component of $M \to \tau^2 M$ is surjective, so that the induced map from $D \text{Hom}_\mathcal{D}(M, \tau^2 N \prod \tau N)$ to $D \text{Hom}_\mathcal{D}(B', \tau^2 N \prod \tau N)$ is injective. Hence the induced map from $D \text{Hom}_\mathcal{D}(\tau^{-1} M, \tau^2 N \prod \tau N)$ to $D \text{Hom}_\mathcal{D}(\tau^{-1} B', \tau^2 N \prod \tau N)$ is injective. So the map from $\text{Ext}^1_\mathcal{D}(N \prod \tau^{-1} N, \tau^{-1} M)$ to $\text{Ext}^1_\mathcal{D}(N \prod \tau^{-1} N, \tau^{-1} B')$ is injective, and therefore the map from $\text{Hom}_\mathcal{D}(N \prod \tau^{-1} N, \tau^{-1} M[1])$ to $\text{Hom}_\mathcal{D}(N \prod \tau^{-1} N, \tau^{-1} B'[1])$ is injective. Hence the map from $\text{Hom}_\mathcal{D}(N \prod \tau^{-1} N, FM)$ to $\text{Hom}_\mathcal{D}(N \prod \tau^{-1} N, FB')$ is injective, and we see that the composition of any non-zero $F$-map from $N \prod \tau^{-1} N$ to $M$ with the $H$-map component of the map $M \to B'$ is non-zero. Note that composition of any such $F$-map with the $F$-map component is always zero. It follows that the composition of any non-zero $F$-map from $N \prod \tau^{-1} N$ to $M$ with the map $M \to B'$ is non-zero. We see that (b) holds and this completes the proof for case I.
Case II: We now assume that $\text{Hom}_H(N, M) = 0$, that there is a non-zero $H$-map from $\tau N$ to $M$ and a non-zero $H$-map from $M$ to $\tau^2 N$. By Lemma 6.3 combined with Lemma 6.6(b), we see that either some non-zero $H$-map from $\tau N$ to $M$ factors through some summand of $T'$ or that some non-zero $H$-map $M \to \tau^2 N$ factors through some summand of $\overline{T}'$.

In the first case we note that, since $\text{Hom}_H(\tau N, M) \cong k$, any non-zero $H$-map from $\tau N$ to $M$ factors through $T'$. Since $\text{Hom}_H(N, M) = 0$, we see that any non-zero $H$-map from $N \bigoplus \tau N$ to $M$ must factor through $T'$, and therefore through $B \to M$, and we see that (a) holds.

The argument in the second case is as in Case I.

Case III: We now assume that there is a non-zero $H$-map from $N$ to $M$, that $\text{Hom}_H(M, \tau^2 N) = 0$ and that there is a non-zero $H$-map from $M$ to $\tau N$. By Lemma 6.3 combined with Lemma 6.6(b), we see that either some non-zero $H$-map from $N$ to $M$ factors through some summand of $T'$ or that some non-zero $H$-map $M \to \tau N$ factors through some summand of $\overline{T}'$.

The argument in the first case is as in Case I.

In the second case, since $\text{Hom}_H(M, \tau^2 N) = 0$, we see that any non-zero $H$-map from $M$ to $\tau^2 N \bigoplus \tau N$ factors through the $H$-map component of $M \to B'$ (noting that an $H$-map between two modules cannot factor through an $F$-map). As in Case I, we see that (b) holds.

Case IV: Finally, we assume that $\text{Hom}_H(N, M) = 0$, $\text{Hom}_H(M, \tau^2 N) = 0$, that there is a non-zero $H$-map from $\tau N$ to $M$ and that there is a non-zero $H$-map from $M$ to $\tau N$. By Lemma 6.3 combined with Lemma 6.6(b), we see that either some non-zero $H$-map from $\tau N$ to $M$ factors through some summand of $T'$ or that some non-zero $H$-map $M \to \tau N$ factors through some summand of $\overline{T}'$.

In the first case we argue as in Case II, and in the second case we argue as in Case III, and this completes the proof for case (IV).

\[ \text{Theorem 6.9.} \] Let $H$ be tame and $N$ be indecomposable exceptional in a tube of rank $n \geq 2$, with $q_1(N) = j \leq n - 2$. Then $N$ is exchange compatible.

\textbf{Proof.} Let $(M, M^*)$ be an exchange pair, with $M$ and $M^*$ complements of some almost complete cluster-tilting object $\overline{T}'$.

Case I: We first assume that $M$ is regular and $M^*$ preprojective. Then we have an exchange sequence $0 \to M^* \to B \to M \to 0$ and an exchange triangle $M \to B' \to M^* \to$. Write $B = B_1 \bigoplus M_1$ and $B' = B'_1 \bigoplus M'_1$, where $M_1$ and $M'_1$ are regular and $B_1$ and $B'_1$ are preprojective. By Lemma 6.8, one of the following holds:

(a) any $H$-map $N \bigoplus \tau N \to M$ factors through $B \to M$;

(b) for any non-zero $F$-map $N \bigoplus \tau^{-1} N \to M$, the composition $N \bigoplus \tau^{-1} N \to M \to M'_1$ is non-zero.

If (a) holds, then we see by Lemma 5.1 that the sequence (3) is exact. If (b) holds, then we see by Lemma 5.3 that the sequence (4) is exact.

Case II: Next, we assume that $M$ and $M^*$ are both preprojective. We can still assume that we have an exchange sequence $0 \to M^* \to B \to M \to 0$ of $H$-modules, so that $B$ is also preprojective. Applying $(N, c)_c$, arguing as in Lemma 5.1 and using that $\text{Hom}_H(N, X) = 0$ for any preprojective $X$, we see that the long exact sequence

\[ (N, \tau^{-1} M)_c \longrightarrow (N, M^*_c) \longrightarrow (N, B)_c \longrightarrow (N, M)_c \longrightarrow (N, \tau M^*)_c \longrightarrow \]

\[ \longrightarrow \longrightarrow \]
reduces to
\[ 0 \rightarrow \text{Ext}_H^1(N, \tau^{-1}M^*) \rightarrow \text{Ext}_H^1(N, \tau^{-1}B) \rightarrow \text{Ext}_H^1(N, \tau^{-1}M) \rightarrow 0. \]

Case III: Finally, we consider the case where both \( M \) and \( M^* \) are regular modules. By Lemma 5.1 (and arguing as in Lemma 5.3), we see that it is enough to show that either of the following hold.

(a) Any \( H \)-map \( N \prod \tau N \rightarrow M \) factors through \( g \) in the sequence
\[ 0 \rightarrow M^* \xrightarrow{f} B \xrightarrow{g} M \rightarrow 0. \tag{7} \]

(b) For any non-zero \( H \)-map \( N \prod \tau^{-1}N \rightarrow M \), the composition with \( h \) is non-zero, where \( h \) is the map in the triangle
\[ \tau^{-1}M^* \rightarrow M \xrightarrow{h} B' \xrightarrow{k} M^*. \]

Note that statement (a) is the same as Lemma 6.8(a). In order to do this, it is clear that we can assume that there is a non-zero \( H \)-map from \( N \prod \tau N \) to \( M \) and that there is a non-zero map (in \( C \)) from \( N \prod \tau^{-1}N \) to \( M \). From the former, it follows that \( N \) and \( M \) must lie in the same tube.

We first of all show the following claim.

**Claim 6.10.** If there is a non-zero \( H \)-map from \( N \prod \tau^{-1}N \) to \( M \) whose composition with \( h \) is zero then any non-zero \( H \)-map from \( N \prod \tau N \) to \( M \) factors through \( g : B \rightarrow M \).

**Proof.** If \( \gamma : N \rightarrow M \) is a non-zero \( H \)-map and the composition \( h \circ \gamma \) is zero, then \( \gamma \) lifts to \( \tau^{-1}M^* \). It follows that \( \tau^{-1}M^* \) lies in the rectangle spanned by \( N \) and \( M \) in the tube (see Figure 6). Hence \( M^* \) lies in the rectangle spanned by \( \tau M \) and \( \tau N \) in the tube (the dashed rectangle in Figure 6). The middle term in the short exact sequence (7) is the direct sum of two indecomposable modules \( B_1 \) and \( B_2 \), which are at the other two corners of the rectangle spanned by \( M \) and \( M^* \). We see from the structure of the tube that \( \gamma \) factors through at least one of \( B_1 \) and \( B_2 \) (using the fact that \( M^* \nless \tau N \)). It follows that \( \gamma \) factors through the map \( B \xrightarrow{g} M \). Since \( \text{Hom}_H(N, M) \simeq k \), we see that every \( H \)-map from \( N \) to \( M \) factors through \( B \xrightarrow{g} M \). \( \square \)

Since a non-zero \( H \)-map from \( \tau N \) to \( M \) factors through any \( H \)-map from \( N \) to \( M \) (note that such maps, if they exist, are unique up to a scalar multiple), it follows that any non-zero \( H \)-map from \( \tau N \) to \( M \) factors through \( B \xrightarrow{g} M \) also. Thus any non-zero \( H \)-map from \( N \prod \tau N \) to \( M \) factors through \( B \xrightarrow{g} M \).

If \( \gamma : \tau^{-1}N \rightarrow M \) is a non-zero \( H \)-map and its composition with \( h \) is zero, then, as above, \( \gamma \) must factor through \( B \xrightarrow{g} M \). Then any non-zero \( H \)-map from \( N \) to \( M \) must factor through \( \gamma \) and therefore, by the above, through \( B \xrightarrow{g} M \). Again arguing as above, we see that any non-zero \( H \)-map from \( \tau N \) to \( M \) factors through \( B \xrightarrow{g} M \) and therefore that any non-zero \( H \)-map from \( N \prod \tau N \) to \( M \) factors through \( B \xrightarrow{g} M \). The claim now follows.

Since \( M \) is regular, Lemma 6.8 applies, and we see that either Lemma 6.8(a) or 6.8(b) holds. If Lemma 6.8(a) holds, then the proof is complete, as statement (a) above is the same as Lemma 6.8(a). If Lemma 6.8(b) holds, then it follows that, for any non-zero \( F \)-map \( N \prod \tau^{-1}N \rightarrow M \), the composition \( N \prod \tau^{-1}N \rightarrow M \rightarrow B' \) is non-zero.

By the claim above, we know that if there is a non-zero \( H \)-map \( N \prod \tau^{-1}N \rightarrow M \) whose composition with \( h \) is zero then statement (a) holds, and the proof is complete. So we are left with the case in which, for any non-zero \( H \)-map or \( F \)-map from \( N \prod \tau^{-1}N \) to \( M \), the composition with \( h \) is non-zero.
Figure 6. Proof of Claim 6.10.

Figure 7. End of proof of Theorem 6.9.

We claim that this means that, for any non-zero map from $N \amalg \tau^{-1}N$ to $M$, the composition $N \amalg \tau^{-1}N \to M \to B'$ is non-zero. We write maps in $C$ between indecomposable objects as pairs $(f, f')$ where $f$ is an $H$-map and $f'$ is an $F$-map. Let $(h, h') : N \to M$ be a non-zero map such that the composition with $M \to B'$ is zero. Then there are maps $(t, t') : N \to \tau^{-1}M^*$ and $(s, s') : \tau^{-1}M^* \to M$ such that $(h, h') = (s, s') \circ (t, t')$. Then $h = st$, so that $h : N \to M$ composed with $M \to B'$ is zero; hence $h = 0$ (as $h$ is a $H$-map). Then $h'$ composed with $M \to B'$ is zero, so $h' = 0$ (as $h'$ is an $F$-map). It follows that $(h, h') = 0$, which is a contradiction. Figure 7 illustrates the above maps.

We see that the map from $(N \amalg \tau^{-1}N, M)_C$ to $(N \amalg \tau^{-1}N, B')_C$ is injective, and thus that statement (b) above holds.

We can now conclude that, if $M \not\cong \tau N \not\cong M^*$, then

$$\dim \text{Hom}_C(N, M) + \dim \text{Hom}_C(N, M^*) = \max(\dim \text{Hom}_C(N, B), \dim \text{Hom}_C(N, B')).$$

Thus $N$ is exchange compatible, and this completes the proof of Theorem 6.9.

**Corollary 6.11.** Let $H$ be a tame hereditary algebra, and let $N$ be an indecomposable exceptional object in $C$. Then $N$ is exchange compatible if and only if $\text{End}_C(N) \cong k$.

**Proof.** This follows immediately from Theorem 6.9 and Corollary 2.8 together with Proposition 2.6.

**Proof of Theorem 1.6.** By Theorem 3.2, Theorem 1.6(a) is equivalent to the following statement.

(a') All indecomposable direct summands $T_i$ of $T$ are exchange compatible.
Figure 8. Cluster variables in Example 7.1.

Figure 9. The quivers $Q$ and $\Gamma$ in Example 7.2.

By Lemma 6.7, Theorem 1.6(c) implies 1.6(b); by Theorem 6.9, Theorem 1.6(b) implies (a'), and, by Corollary 2.5, (a') implies Theorem 1.6(c). The proof is complete.

7. Examples

In this final section we give two examples to illustrate our main result.

Example 7.1. We consider a Dynkin quiver $Q$ of type $A_3$, and choose a cluster $\{y_1, y_2, y_3\}$ with the following cyclic quiver.

\[
\Gamma : \begin{array}{c}
1 \\
\downarrow \\
2 \\
\downarrow \\
3
\end{array}
\]

If we choose a cluster-tilting object $T$ where the quiver of $\text{End}_C(T)^{\text{op}}$ is $Q'$ and compute all cluster variables with respect to the initial cluster $\{y_1, y_2, y_3\}$, we get the picture shown in Figure 8, where in the AR-quiver we have represented the indecomposable objects by their corresponding cluster variables.

It is easily verified here that the denominators are all of the prescribed form, as promised by Theorem 1.5.

Example 7.2. In the next example we consider the quiver $Q$ shown in Figure 9(a). This is mutation equivalent to the quiver $\Gamma$ shown in Figure 9(b). Then the AR-quiver of $kQ$ has a tube of rank two with quasisimple modules given by the simple module $S_2$ and $M = \tau S_2$, a module with composition factors $S_1$ and $S_3$. We choose a cluster-tilting object $T$ such that the quiver of the cluster-tilted algebra $\text{End}_C(T)^{\text{op}}$ is $\Gamma$, for example, $T = T_1 \bigsqcup T_2 \bigsqcup T_3 = P_1 \bigsqcup M \bigsqcup P_3$. Then $\tau T = \tau P_1 \bigsqcup S_2 \bigsqcup \tau P_3$.

Let $y_i$ be the cluster variable corresponding to $\tau T_i$ for $i = 1, 2, 3$. Then there is a seed $((y_1, y_2, y_3), \Gamma)$ of $A(Q)$. The cluster variables corresponding to some of the objects in the preprojective/preinjective component of the AR-quiver of $C_{kQ}$ are shown in Figure 10.
The cluster variables corresponding to the two quasisimple modules in the tube of rank two are $y_2$, corresponding to $\tau M = S_2$, and $((y_1 + y_3)^2 + y_2)/y_1y_2y_3$, corresponding to $M$. However, $\text{Hom}_C(T_2, M) = \text{End}_C(M)$ is easily seen to be two-dimensional, while $y_2$ appears with multiplicity one in the denominator of the cluster variable corresponding to $M$.

We remark that, using the above counter-example, Fu and Keller have discovered a counter-example (see [15]) to Conjecture 7.17 of [14]; see also [17].

Acknowledgement. The authors would like to thank the referee for helpful comments on the first version of this article.
