Pd local structure and size correlations to the activity of Pd/TiO₂ for photocatalytic reforming of methanol
Norli Abdullah, Hasliza Bahruji,* Scott M. Rogers, Peter P. Wells, Richard A. Catlow and Michael Bowker

The interaction between Pd and TiO₂ for promoting photocatalytic activity was investigated by tailoring the size of Pd nanoparticles and monitoring the photocatalytic activity of methanol photo-reforming reaction for hydrogen gas production.

Please check this proof carefully. Our staff will not read it in detail after you have returned it.

Please send your corrections either as a copy of the proof PDF with electronic notes attached or as a list of corrections. Do not edit the text within the PDF or send a revised manuscript as we will not be able to apply your corrections. Corrections at this stage should be minor and not involve extensive changes.

Proof corrections must be returned as a single set of corrections, approved by all co-authors. No further corrections can be made after you have submitted your proof corrections as we will publish your article online as soon as possible after they are received.

Please ensure that:
- The spelling and format of all author names and affiliations are checked carefully. You can check how we have identified the authors’ first and last names in the researcher information table on the next page. Names will be indexed and cited as shown on the proof, so these must be correct.
- Any funding bodies have been acknowledged appropriately and included both in the paper and in the funder information table on the next page.
- All of the editor’s queries are answered.
- Any necessary attachments, such as updated images or ESI files, are provided.

Translation errors can occur during conversion to typesetting systems so you need to read the whole proof. In particular please check tables, equations, numerical data, figures and graphics, and references carefully.

Please return your final corrections, where possible within 48 hours of receipt, by e-mail to: pccp@rsc.org. If you require more time, please notify us by email.
Funding information

Providing accurate funding information will enable us to help you comply with your funders’ reporting mandates. Clear acknowledgement of funder support is an important consideration in funding evaluation and can increase your chances of securing funding in the future.

We work closely with Crossref to make your research discoverable through the Funding Data search tool (http://search.crossref.org/funding). Funding Data provides a reliable way to track the impact of the work that funders support. Accurate funder information will also help us (i) identify articles that are mandated to be deposited in *PubMed Central (PMC)* and deposit these on your behalf, and (ii) identify articles funded as part of the *CHORUS* initiative and display the Accepted Manuscript on our web site after an embargo period of 12 months.

Further information can be found on our webpage (http://rsc.li/funding-info).

What we do with funding information

We have combined the information you gave us on submission with the information in your acknowledgements. This will help ensure the funding information is as complete as possible and matches funders listed in the Crossref Funder Registry.

If a funding organisation you included in your acknowledgements or on submission of your article is not currently listed in the registry it will not appear in the table on this page. We can only deposit data if funders are already listed in the Crossref Funder Registry, but we will pass all funding information on to Crossref so that additional funders can be included in future.

Please check your funding information

The table below contains the information we will share with Crossref so that your article can be found via the Funding Data search tool. Please check that the funder names and grant numbers in the table are correct and indicate if any changes are necessary to the Acknowledgements text.

| Funder name                                              | Funder’s main country of origin | Funder ID (for RSC use only) | Award/grant number |

Researcher information

Please check that the researcher information in the table below is correct, including the spelling and formatting of all author names, and that the authors’ first, middle and last names have been correctly identified. Names will be indexed and cited as shown on the proof, so these must be correct.

If any authors have ORCID or ResearcherID details that are not listed below, please provide these with your proof corrections. Please ensure that the ORCID and ResearcherID details listed below have been assigned to the correct author. Authors should have their own unique ORCID iD and should not use another researcher’s, as errors will delay publication.

Please also update your account on our online manuscript submission system to add your ORCID details, which will then be automatically included in all future submissions. See here for step-by-step instructions and more information on author identifiers.

Pd local structure and size correlations to the activity of Pd/TiO\textsubscript{2} for photocatalytic reforming of methanol

Norli Abdullah\textsuperscript{a,b,c} Hasliza Bahruji,\textsuperscript{d} Scott M. Rogers,\textsuperscript{d} Scott M. Rogers,\textsuperscript{d} Peter P. Wells,\textsuperscript{e,f} Richard A. Catlow\textsuperscript{a,b,g} and Michael Bowker\textsuperscript{d,a,g}

The interaction between Pd and TiO\textsubscript{2} for promoting photocatalytic activity was investigated by tailoring the size of Pd nanoparticles and monitoring the photocatalytic activity of methanol photo-reforming reaction for hydrogen gas production. We show that at 0.6 wt% Pd loading, the catalyst with highly dispersed nanoparticles obtained at 1 \textdegree C temperature exhibits superior photocatalytic activity for hydrogen gas production. At different weights of Pd loading, tailoring two sets of catalysts with different structural properties provides correlation between the changes in the Pd local structures and the rate of hydrogen production. The impact of controlling the structural properties of metal nanoparticles on influencing H\textsubscript{2} production outweighs the effect of metal loading variation. The differences of Pd/TiO\textsubscript{2} activity at the different metal loading were correlated with the changes in the Pd local structure consequently affecting the electronic transfer and photocatalytic efficiency.

Introduction

Photocatalytic hydrogen production offers a green sustainable route for clean and renewable energy.\textsuperscript{1,2} The performance of TiO\textsubscript{2} is greatly enhanced by the deposition of metal nanoparticles; Pt/TiO\textsubscript{2}, Au/TiO\textsubscript{2} and Pd/TiO\textsubscript{2} catalysts have been widely investigated and shown to promote hydrogen generation with UV light.\textsuperscript{3–8} The enhanced activity is associated with the ability of the photo-induced electron in the conduction band of TiO\textsubscript{2} to be transferred to the metal co-catalysts.\textsuperscript{9,10} Such transfer occurs at the metal island and the periphery of the TiO\textsubscript{2} interface, which promotes electron–hole separation and consequently extends the lifetime of the energy carriers.\textsuperscript{11} The work function differences between the metal and TiO\textsubscript{2} semiconductor create a Schottky barrier that allows spontaneous injection of photo-generated electrons from the conduction band of TiO\textsubscript{2} into the metal.\textsuperscript{12} The interfacial charge transfer between TiO\textsubscript{2} and the metal is a single electron transfer process, although hydrogen generation from water and methanol photo-reforming reaction requires a multi-electron transfer reaction.\textsuperscript{13} In order to improve the electronic transfer at the metal–TiO\textsubscript{2} interface, we must note that the efficiency relies strongly on the interfacial atomic geometry of metal nanoparticles and TiO\textsubscript{2}.\textsuperscript{14} Understanding the geometric strain at metal/TiO\textsubscript{2} is important for designing an active catalyst. Au nanoparticles deposited on TiO\textsubscript{2} with 3–30 nm size produced hydrogen gas from ethanol, but with 3–12 nm size, the effect of size variation was less significant.\textsuperscript{15} We proposed in our previous studies that the catalytic activity is significantly correlated to Pd loading, with high activity achieved at very low Pd loading.\textsuperscript{11} Model studies by Bloh et al. found that the optimal metal to TiO\textsubscript{2} ratio \textasciitilde 2.4 doping atoms per nanometer of particle size was required for an ideal catalytic improvement.\textsuperscript{16} Exceeding this ratio causes the metal to act as a recombination centre. The decrease in activity at high loading is due to the shadowing effect of metal nanoparticles that reduced the light penetration onto TiO\textsubscript{2}.\textsuperscript{17} Excess metal nanoparticles on TiO\textsubscript{2} are also suggested to become electron and hole trapping sites.\textsuperscript{18,19}

Pd is a precious noble metal with a large work function to trap electrons for efficient electron hole separation. We have previously investigated the activity of Pd/TiO\textsubscript{2} for photocatalytic reforming of alcohols with the mechanism of hydrogen
production involving dehydrogenation of alcohol on the Pd surface and water reduction occurring at the Pd–TiO2 interface.\textsuperscript{20−23} The efficiency of Pd to promote electron transfer from the conduction band of the semiconductor is not limited to TiO2, but studies on visible light driven photocatalysts such as BiFeO3 and GaN–ZnO showed enhancement in the photocatalytic performance for hydrogen production.\textsuperscript{24−26} Alteration of the Pd morphology to nanocubes improved the hydrogen production from Pd/2D-C3N4 composites due to the efficient separation of photogenerated energy carriers.\textsuperscript{27} Understanding the role of the metal nanoparticles in promoting the catalytic activity of TiO2 is often hampered by morphology alterations, particularly at high metal loading.\textsuperscript{15} The aims of the work are to improve the Pd/TiO2 photocatalytic activity and to gain fundamental understanding of structural changes of Pd upon variation of metal loading. In these studies, tailored Pd metal nanoparticles were prepared using the controlled kinetic growth of Pd colloids via synthesis temperature variations to obtain Pd nanoparticles of different but controlled nanoparticle sizes. Systematic Pd/TiO2 catalyst design managed to differentiate the promotional effect caused by the size of Pd nanoparticles and the amount of metal loading, allowing us to gain an understanding of the effect of the Pd–TiO2 interaction on promoting hydrogen production from photocatalytic reforming of methanol:

\[ \text{CH}_3\text{OH} + \text{H}_2\text{O} + h\nu \rightarrow 3\text{H}_2 + \text{CO}_2 \]

**Results**

To enhance the activity of Pd/TiO2 catalysts, the particle size of Pd was tailored by controlling the synthesis temperature of the Pd colloid at a fixed loading of 0.6 wt%. EXAFS is a useful technique that allows the study of nanoparticles and provides local structural information of palladium. The local coordination of Pd was obtained by recording ex situ Pd K-edge EXAFS spectra of catalysts after drying at ambient temperature (Fig. 1). Ex situ Pd K-edge EXAFS spectra were recorded for 0.6 Pd wt% TiO2 catalysts when Pd synthesis was carried out at temperatures of 1 °C, 25 °C, 50 °C and 75 °C. The Pd K-edge XANES of 0.6% Pd/TiO2 prepared at 1 °C shows the Pd environment of the samples corresponding to the Pd metal with a Pd–Pd distance of 2.78 Å.\textsuperscript{28} The sample also shows the peak associated with the Pd–O first shell with a distance of 2.00 Å.\textsuperscript{29} The absence of a second shell of Pd–O–Pd at 3.3 Å evidences that the Pd particles may exist as a subnanometer Pd cluster.\textsuperscript{30} As the synthesis temperature increased to 25 °C, the Pd–O first shell peak height with a distance of 1.99 Å decreased accompanied by an increase of the Pd–Pd peak with a radius distance of 2.74 Å, suggesting the growth of Pd\textsuperscript{0} nanoparticles. The amplitude of the Pd–O first shell decreased with the temperature, which correlates well with the increasing intensity of the Pd–Pd peak at 2.74 Å. This signifies the enlargement of Pd metal nanoparticles as the temperature of the colloidal Pd solution was increased up to 75 °C.\textsuperscript{31} The EXAFS fitting parameter in Table 1 also revealed the coordination number of the Pd–Pd and Pd–O first shell. It is clear that the Pd–O first shell coordination number reduced from 2.8 for the catalyst obtained at 1 °C to 0.7 as the temperature increased to 75 °C. In contrast, the Pd–Pd coordination numbers increased from 2.8 to 8.4. The variation of the coordination number is associated with the structural and morphological changes, which in this case are due to the enlargement of Pd nanoparticles as the temperature of the colloidal Pd solution increased.\textsuperscript{32} We can conclude that there are no large PdO crystallites and rather the PdO component originates from the surface oxide, due to the absence of the Pd–Pd scattering at 3.00 Å, which would occur in such crystallites.

**Fig. 1** k\textsubscript{3} weighted Fourier transform (magnitude) EXAFS data for the 0.6 wt% Pd/TiO2 catalysts prepared at 1 °C, 25 °C, 50 °C and 75 °C.
nanoparticle size continues to grow with an average diameter of 3.8 nm for 50 °C synthesis, and 5.2 nm for 75 °C. In general, upon increasing the synthesis temperature for the 0.6% Pd/TiO₂ catalyst, the Pd–O (at 2.00 Å) coordination increases meanwhile the Pd–Pd (2.78 Å) coordination decreases, with decreasing average Pd particle size.

The resulting 0.6% Pd/TiO₂ catalysts were subsequently used in photocatalytic hydrogen generation by photoreforming of methanol. Fig. 3 shows the plot of hydrogen gas production analysed for every 30 minutes during 3 h reaction. The 0.6% Pd/TiO₂ catalyst obtained from the colloidal sol that was prepared at 1 °C, produced ~676 μmol of H₂ in 3 h of reaction. The value is significantly higher than that of the rest of the catalysts at a similar weight loading.

As the temperature of the colloidal sol increases, the results of the 0.6% Pd/TiO₂ catalysts showed that the hydrogen generation is significantly affected with the total hydrogen volume reduced to ~434 μmol for the catalyst produced at 25 °C, 230 μmol for 50 °C and only 186 μmol when the synthesis temperature was raised to 75 °C. The increased activity of 0.6% Pd/TiO₂ catalysts produced at 1 °C was compared with our previous finding in which the rate of hydrogen production showed a twofold enhancement in comparison with Pd/TiO₂ produced via an impregnation method.¹⁰,²⁰

As the impact of controlling the size of metal nanoparticles on increasing H₂ productivity is dramatic, we therefore increased the Pd metal loading to study its effect on photocatalytic performance. The Pd loadings were varied at 0.6 wt%, 1 wt%, 2 wt% and 4 wt%. Two sets of catalysts were prepared at different weight loadings, with the first set of catalysts produced at 1 °C to ensure that a narrow Pd nanoparticle distribution was achieved. The second set of catalysts was prepared by varying the synthesis temperature in order to obtain Pd nanoparticles with similar particle sizes. TEM analysis data in Table 1 showed that the particle size of Pd on TiO₂ increases with the amount of metal loading, despite the undertaking of the synthesis at 1 °C. Fig. 4 shows the TEM images of 1%, 2% and 4% Pd/TiO₂, and the particle size distribution histogram obtained from the sol immobilisation method carried out at 1 °C. Pd at 1% loading shows a Pd diameter of 2.6 nm meanwhile at 2% loading, the average diameter was measured to be 3.5 nm. As the Pd loading increases, the size increases to 3.8 nm at 4% loading.

### Table 1

| Catalysts     | Pd size/nm | Abs. Sc.   | N  | R/Å  | 2/A | E₀/eV | R_FACTOR |

### Fig. 3
 Photocatalytic hydrogen production from methanol on 0.6 wt% Pd/TiO₂ prepared at different synthesis temperatures.
Table 1 also shows the XAFS analysis data of the Pd/TiO₂ catalysts at different weight loadings. The value of Pd–Pd coordination number increased with the amount of Pd loading, implying that larger Pd particles were produced at higher Pd loadings. Similar occurrences for the Pd²⁺/Pd⁰ ratios derived from the XANES analysis revealed that the ratio decreases with the amount of Pd loading, from 1.32 at 1% Pd, to 0.53 at 2% Pd and 0.49 at 4% Pd loading. In general, for the first set of catalysts obtained at 1°C, the amount of Pd loading was varied in the range of 0.6–4 wt%, producing catalysts with an average Pd nanoparticle size of 2–4 nm, with the Pd²⁺/Pd⁰ ratios in the range of 2.2–0.49. The catalysts were subsequently used for photocatalytic hydrogen production by photoreforming of methanol. The plot of hydrogen production against reaction time when using the first set of catalysts is shown in Fig. 5a. The catalysts produced a high volume of hydrogen within 3 h of reaction at low Pd loading, with ~636 μmol of hydrogen for 0.6% Pd loading. The volume was significantly reduced to 512 μmol for 1% Pd/TiO₂. As the Pd loading was increased, the photocatalytic activity of the catalysts was significantly reduced with only ~181 μmol of hydrogen produced at 4% Pd loading.

The decrease of TiO₂ activity at high metal loading is often related to the shadowing effect of the metal that reduces the TiO₂ photosensitivity.¹⁷ To gain further understanding of the factors influencing the catalytic activity at high metal loading, the second set of catalysts was used for the evaluation of photocatalytic performance. The catalysts were obtained by varying the synthesis temperature for 0.6 wt%, 1 wt%, 2 wt% and 4 wt% of Pd in order to produce catalysts with approximately similar Pd nanoparticle intrinsic structural properties. For 0.6% Pd/TiO₂ and 1% Pd/TiO₂ catalysts, the synthesis temperature was set at 50°C, meanwhile for 2% and 4% Pd/TiO₂ catalysts, the temperature was set at 1°C to give a Pd diameter of 3.5 nm. The list of particle sizes of Pd nanoparticles analysed using TEM and the local structure of Pd from XAFS analysis are summarised in Table 1. Apart from similar Pd diameters within 3.3–3.8 nm, the catalysts also consisted of palladium nanoparticles with approximately similar Pd²⁺/Pd⁰ ratios ~0.43–0.53 (Table 1). The photocatalytic performance of the catalysts for hydrogen gas production is shown in Fig. 5b. The catalysts produced similar rates of hydrogen production with the volume of hydrogen production ~180 to 230 μmol in 3 h of reaction. In comparison to the first set of catalysts that were produced at 1°C, controlling the size of Pd nanoparticles around 3.5 nm appears to reduce the differences in the catalytic performance of Pd/TiO₂ catalysts despite the different weights of metal loading deposited on TiO₂.

**Discussion**

We tailored the size of Pd nanoparticles deposited on TiO₂ by controlling the kinetic growth of Pd in the sol solutions. The correlations between the catalytic performance, and the size and local structure of Pd for 0.6% Pd obtained at different temperatures are shown in Fig. 6. The catalyst obtained from the colloids prepared at 1°C with an average Pd diameter of 2.3 nm shows superior activity for hydrogen production. The photocatalytic performance is appreciably reduced upon increasing the size of Pd particles. Fig. 6 also shows a clear relationship between the extent of Pd²⁺ and the Pd particle diameter by TEM.
The presence of Pd\textsuperscript{2+} in the oxidic surface layer of Pd is associated with the surface contribution of Pd to form an interfacial interaction with TiO\textsubscript{2}. It is important for Pd to be in the Pd\textsuperscript{0} oxidation state in order to catalyse the hydrogen production steps.\textsuperscript{6} PdO on TiO\textsubscript{2} is reduced to Pd\textsuperscript{0} in the presence of methanol under UV irradiation prior to sustainable hydrogen production from methanol.\textsuperscript{10} The susceptibility of Pd\textsuperscript{2+} to accept an electron increased the efficiency of photogenerated electron trapping that occurs at the Pd–TiO\textsubscript{2} interface. The small Pd nanoparticles on TiO\textsubscript{2} enhanced the interfacial interaction between TiO\textsubscript{2} and palladium, subsequently promoting the efficient electronic transfer from the conduction bands of TiO\textsubscript{2} to the Pd metal. Clearly, at a similar metal loading, the catalytic activity in promoting hydrogen generation is significantly influenced by the particle size of Pd, which we relate to the surface Pd–TiO\textsubscript{2} interaction. Since all the catalysts were pre-treated under similar conditions, i.e. drying at room temperature prior to the reaction, a strong metal support interaction that often occurs via high temperature annealing is not applicable in this case. However, generating small Pd nanoparticles produced a higher degree of interfacial interaction between TiO\textsubscript{2} and palladium. The increase in the oxide–metal interface area promotes the Schottky effect for electron excitation and subsequently enhances the electronic transfer between the conduction bands of TiO\textsubscript{2} and the Pd.

Understanding the fundamental aspect of the effect of particle size and metal weight loading is a challenging task due to the agglomeration of nanoparticles at high metal loading. Controlling the particle size of Pd while increasing the weight of the metal deposited on TiO\textsubscript{2} allows an understanding of the geometric influence of Pd nanoparticles on photocatalytic performance. Fig. 7a shows the hydrogen production rate dependence on Pd loading and the normalised H\textsubscript{2} rate over Pd loading for the first set of catalysts with an average Pd size of 2–4 nm. The rate of hydrogen evolution is significantly reduced as the Pd loading increased to 4%. When the activity is normalised to the amount of Pd loading, the differences in the catalytic activity are even more significant. Varying the amount of metal loading is often associated with the agglomeration of nanoparticles particularly at high metal loading, thus altering the local structure of the metal. This proved that the reduction of Pd/TiO\textsubscript{2} activity at high metal loading is due to the differences in the Pd local structure that affected the efficiency of electronic transfer at Pd–TiO\textsubscript{2} interfaces.

On the other hand, the second set of Pd/TiO\textsubscript{2} catalysts prepared by varying the synthesis temperature showed a near invariant rate of hydrogen evolution of \( \sim 80 \mu \text{mol h}^{-1} \) regardless of the amount of Pd loading. When the rate of hydrogen production is normalised to the amount of Pd content, there is only a slight decrease in the hydrogen production rate at higher Pd loading (Fig. 7b). A linear relationship was observed between the rate of hydrogen and the amount of Pd loading implying a similar Pd local structure of the catalysts. We can deduce that the catalytic activity is affected by Pd structural properties, and varies little with the loading amount. The results showed that the impact of controlling the amount of surface palladium interacting with TiO\textsubscript{2} in increasing H\textsubscript{2} productivity outweighs the effect of metal weight loading.

**Experimental**

**Catalyst preparation**

To synthesise the Pd colloidal sol, PVA was used as a stabiliser ligand with NaBH\textsubscript{4} as the reducing agent. The size of Pd nanoparticles was controlled by controlling the temperature of Pd nucleation, in which the kinetic growth was altered by variation of the temperature from 1–75 °C. This method was previously reported for Au and found to be reliable for the synthesis of small Au nanoparticles.\textsuperscript{33} An aqueous solution of K\textsubscript{2}PdCl\textsubscript{4} (Alfa Aesar, 99.9% metal basis) at the desired concentration was prepared. Polyvinylalcohol (PVA) (1 wt% solution, Aldrich, \( M_w = 10 000, 80\% \) hydrolysed) was added (PVA/Pd = 0.65 weight ratio). A 0.1 M freshly prepared solution of NaBH\textsubscript{4} (> 96% Aldrich, NaBH\textsubscript{4}/Pd = 5 molar ratio) was then added to form a dark-brown sol. After 30 min of sol generation, the colloid was immobilised by adding TiO\textsubscript{2} (acidified at pH 1 by sulphuric acid) under vigorous stirring conditions. After 2 h, the slurry was filtered and washed with deionised water before drying in air at ambient temperature for 16 hours. Palladium loading was varied at 0.6 wt%, 1 wt% and 2 wt% and 4 wt% on the TiO\textsubscript{2} P25 support. Detailed experimental procedures and characterisation data are available in the ESL.\textsuperscript{†}

**Photocatalytic measurement**

Photocatalytic activity was determined from gas phase photo-reforming of methanol under UV irradiation (280–380 nm). 50 mg of the catalyst was mixed with water to form a paste and was dispersed on a glass slide with an irradiated area of the film of \( \sim 7.5 \text{ cm}^2 \). The catalyst was left to dry under ambient conditions.
The glass slide was then placed on a three neck flask containing 15 ml of water and 100 µl of methanol. The system was purged with Ar for 30 minutes and sealed using a rubber stopper. The catalyst was irradiated using an Oriel Xe lamp with 150 Watt from the side of the flask. A gas sample was analysed every 30 min for 3 hours using a PerkinElmer Clarus GC with a TCD detector.

Conclusions
Temperature controlled immobilisation of Pd on TiO2 is a reliable method to produce tailored Pd nanoparticles with controlled size and local structures. In correlation with the TEM and XAFS analysis, it is clear that reducing the size of Pd nanoparticles while maintaining the amount of metal weight loading significantly enhanced the photocatalytic activity of Pd/TiO2. Tailoring two sets of catalysts, in which the particle diameter and local structure of Pd were tailored to be approximately similar, showed negligible differences in the rate of hydrogen generation. The presence of surface Pd^2+ to accept an electron from the conduction band of TiO2 increased the efficiency of photogenerated electron trapping that occurs at the Pd–TiO2 interface. This shows the dominant effect of the Pd size and local structure in influencing the photocatalytic activity of the Pd/TiO2 catalyst for hydrogen production from photoreforming of methanol.

Conflicts of interest
There are no conflicts to declare.

Acknowledgements
The authors would like to acknowledge UK Catalysis Hub and EPSRC for research funding to H. Bahruij through grant EP/L038748/1. The Ministry of Education, Malaysia (MOE) is thanked for financial support for a Post-doctoral award to N. Abdullah.
