Institute for High Energy Physics, 142 281, Protvino, Russia

\textbf{Abstract.} The average charged hadron multiplicities induced by top quark decays are calculated in pQCD at LHC energies. Different modes of top production are considered. Proposed measurements can be used as an additional test of pQCD calculations independent on a fragmentation model.

1 Introduction

The study of unstable heavy particles like W, Z bosons, top quarks and others (arising in different extensions of the Standard Model) is one of the leading directions in the modern high energy physics. To determine particle parameters (charge, mass, width, decay modes etc.) we have to look deep inside their production and decay mechanisms.

In this article processes with top production are considered due to its specific properties. Top quark is extremely elusive object. Because its mass is so large (~ 172 GeV), the top quark production is considered due to its specific properties. Top quark is extremely elusive object. Because its mass is so large (~ 172 GeV), the top quark production is extremely small compared to that of lighter quarks. The top quark decay proceeds extremely fast, in less than 5 × 10^{-22} s, which is shorter than the time scale to form hadrons τ_{had} \approx 1/Λ_{QCD} \approx 3 × 10^{-24} s and almost 13 orders of magnitude smaller than the lifetime of hadrons, which involve the next heaviest quark, τ_{t} \approx 1.5 × 10^{-12} s. The width Γ_{t} acts as a physical "smearing", and the top production becomes a quantitative prediction of pQCD, largely independent on nonperturbative phenomenological algorithms. That is why top measurements are directly related to pQCD tests.

The principal observables used in tests of pQCD are typically measurements of jets, high transverse momentum particles and event shapes. There are relative advantages and disadvantages in using these observables. Jet measurements are expected to have a close correlation in direction and momentum with the parton which gave rise to it. However, several complications concerning jet definitions (algorithms) arise when using jet measurements. While the infrared and collinear safety of event shapes allows safe perturbative predictions, we have to take into account resummation of large logarithms. Evolution of structure functions can be predicted by pQCD calculations, but we have to consider different kinematical regimes (see, for example, recent review on QCD tests \cite{2}).

The QCD radiation associated with \ttbar production has been treated earlier in \cite{12,13}. These papers consider the effect, that gluons are also radiated from the b’s from t-decay. This effect has been also taken into account here. Recently top production at the ILC e^{+}e^{-} collider was considered \cite{3}. Following the basic idea of Ref. \cite{1} it is possible to analyse the case of top production at the LHC. Since in pp events the energy of parton interaction is not fixed and changes in the range from about 400 GeV up to several TeV, we can study the evolution of average multiplicities.
in this energy domain. Of course, several obvious difficulties can arise (color interconnection, interference effects). It is shown, that there are some cases where we can successfully avoid the above complications.

The paper is organized as follows. In the first section there is an outlook of the basic model. The second one is devoted to numerical results for different mechanisms of the top production at the LHC. Complicated formulae and calculations are collected in Appendices.

2 Model

The model used in this section is analogous to the one presented in [3]. In this article we consider processes of the type $p + p \rightarrow t \bar{t} + X$ or $p + p \rightarrow t + X$ (see Fig. 1). The basic formula for inclusive production of the system $M$ in the collinear approximation looks as follows

$$\frac{d\sigma_{pp \rightarrow M}}{dx_1 dx_2 d\Phi_M} \chi(s) = \sum_{i,j} f_i(x_1)f_j(x_2) \frac{d\sigma_{ij \rightarrow M}}{d\Phi_M}(x_1 x_2 s; \{\Phi_M\}),$$

(1)

where $f_i(x)$ is the probability to find parton $i$ (quark, antiquark or gluon) with the longitudinal momentum $x \sqrt{s}/2$ in a proton. Renormalization and factorization scales are hidden in $f$ and $\sigma$. Here $M$ is the system of different final states like $t\bar{t}$, $tb$, $tq$, $tW$, which corresponds to different mechanisms of the inclusive top production at the LHC. $X$ includes beam remnants ($X_{beam}$) and also the secondary radiation induced by color interactions inside $M$ ($X_{M-beam}$) plus possible interaction between $M$ and beam remnants ($X_{M-beam}$), if $M$ is not a color singlet. Variables $x_{1,2}$ are fixed in every separate event and can be calculated experimentally. Usually the sum in (1) can be approximated by a single factorized term which includes parton distributions multiplied by the amplitude squared of parton-parton cross-sections:

$$g + g \rightarrow t\bar{t} + X_M \,(\text{dominates at the LHC}),$$

(2)

$$q + q' \rightarrow W^+ \rightarrow t\bar{b} + X_M,$$

(3)

$$b + q \rightarrow tq' + X_M,$$

(4)

$$b + g \rightarrow tW + X_M,$$

(5)

$$g + g \rightarrow tW + X_M,$$

(6)

$$g + g \rightarrow tW + X_M,$$

(7)

where $q$, $q'$ denotes corresponding light quarks. For our purposes it is enough to consider initial parton collisions instead of pp process, since we have to calculate only the charged hadron multiplicity of the $M$ plus $X_M$ in a separate event. Complications concerning $X_{beam}$ and $X_{M-beam}$ are discussed below. $X_M$ comes from virtual gluon radiation.

For the average multiplicity of hadrons in $M + X_M$ we can use the expression similar to Eq. (5) in [3]:

$$N_{M+X_M}^h(Q^2) = n_M +$$

$$\int \frac{d^4k}{(2\pi)^4} \Pi_{ab}^{\mu\nu}(q_1, q_2, k) d_{ab}^{\mu\nu}(k) d_{ab}^{\nu\mu}(k) n_{a\beta}^\gamma(k),$$

(8)

where $d_{ab}^{\mu\nu}(k) \equiv i d_{ab}^{\mu\nu}(k)/(k^2 + i\delta)$ is the propagator of the gluon with momentum $k$, $q_1, 2$ are momenta of initial partons. Here and below $(a, b)$ and $(a', b')$ denote color indices, $Q = \sqrt{(q_1 + q_2)^2}$ is the energy of colliding partons.

The first term in the r.h.s. of Eq. (8), $n_M$, is the multiplicity from the fragmentation of leading particles in the final state. For example, in the process $p + p \rightarrow n_M = n_{t\bar{t}} = n_t$, where $n_t$ was calculated in [4]. In other processes $n_M$ is appropriate combination of multiplicities which are taken from the analysis of data and pQCD calculations:

$$n_{t\bar{t}} = n_{t} = n_{t}(t \rightarrow \text{hadrons}) = 41.03 \pm 0.54 \text{[4]},$$

(9)

$$n_{tW} = n_{t}(t \rightarrow l\bar{b} + \text{hadrons}) = 21.9 \pm 0.53 \text{[4]},$$

(10)

$$n_{c} = 2.6, n_{b} = 5.5 \text{[10]}, n_{q} = 1.2 \text{[10]},$$

(11)

Tensor $n_{a\beta}^\gamma(k)$ is given in [3]:

$$n_{a\beta}^\gamma(k) = (-g_{a\beta}k^2 + k_{a}k_{\beta}) \delta^{\alpha\nu} n_g(k^2),$$

(13)

where dimensionless quantity $n_g(k^2)$ describes the average multiplicity of hadrons in the gluon jet with the virtuality $k^2$. It is, of course, gauge invariant, and depends only on the virtuality $k^2$.

The quantity $n_g(k^2)$ cannot be calculated perturbatively. It is usually assumed that the average hadron multiplicity is proportional to $n_g(k^2, Q_0^2)$, i.e. the average multiplicity of (off-shell) partons with the “mass” $Q_0$ (the so-called local parton-hadron duality):

$$n_g(k^2) = n_g(k^2, Q_0^2) K(Q_0^2),$$

(14)

where $K(Q_0^2)$ is a phenomenological energy-independent factor. The QCD evolution equations for both $n_g(k^2, Q_0^2)$
and
\[ N_g(k^2, Q_0^2) = \int \frac{dp^2}{p^2} n_g(p^2, Q_0^2) \]
(15)
are derived in [3], and also in old works [15,16]. We use the “conventional standard” value $Q_0 = 1$ GeV for further numerical calculations. Here $N_g(k^2, Q_0^2)$ is the average multiplicity from the gluon jet whose virtuality $p^2$ varies up to $k^2$. Very often $N_g$ is erroneously called the average multiplicity of the gluon jet with fixed virtuality $k^2$. This meaning should be addressed to $n_g$ only.

In this paper we will use two phenomenological expressions (to estimate theoretical uncertainties) for $n_g$ which can be found in [3]:
\[ n_g^1(k^2) = k^2 \frac{d}{dk^2} N_g^1(k^2, Q_0^2), \]
(16)
\[ N_g^1(k^2) = 3.89 + 0.01 \exp \left( 1.63 \sqrt{\ln \left( \frac{k^2}{\Lambda_t^2} \right)} \right), \]
(17)
\[ A_1 = 0.87 \text{ GeV} \text{(QCD motivated)}, \]
(17a)
\[ N_g^2(k^2) = 4.21 + 0.012 \ln^2 \left( \frac{k^2}{\Lambda_t^2} \right), \]
(18)
\[ A_2 = 0.93 \text{ GeV}. \]
(18a)
Parameters for these functions were obtained in [4] (see eq.(3) and Fig.8 in this reference, where $n_g$ corresponds to the function $N_g$ in the present paper) by the fitting of the data from [11].

In Eq. (5) the first factor of the integrand is given by
\[ \Pi^{ab}_{\mu\nu}(q_1, q_2, k) = \prod_{i=1}^{N_{i,n,q1}} \left[ \tilde{d}^{\rho_i \sigma_i}(q_1, n) \delta_{\alpha_i, \beta_i} \right] \times \Pi^{(a,b); \mu \nu}_{\rho \sigma}(q_1, q_2, k), \]
(19)
where $\Pi^{(a,b); \mu \nu}_{\rho \sigma}(q_1, q_2, k)$ can be calculated in the first order in the strong coupling constant as the amplitude squared of the corresponding process (2)-(7) with $X_M = g$ normalized to the total rate of the process without $X_M$.

Sum in the product of polarization vectors of initial gluons ($N_{i,n,q1}$ = 0, 1, 2) forms usual factor (here we use the axial gauge since it simplifies much theoretical calculations)
\[ \tilde{d}^{\rho_i \sigma_i}(q_1, n) = \sum_{\lambda=1,2} c^\rho_{i(\lambda)}, c^\sigma_{i(\lambda)} = -g^{\rho \sigma \alpha \beta} q^{\alpha \beta} q^{\rho i} q^{\sigma i}, \]
(20)
where $c_{i(\lambda)} q_{\mu \nu} = 0$, $q_1^2 = 0$, $n$ is an appropriate four-vector in the corresponding process (see Appendices B,C).

The quantity (19) satisfies the equality
\[ k^\mu \Pi^{ab}_{\mu\nu}(q_1, q_2, k) = 0 \]
(21)
due to the general theorem [17]: If the QCD amplitude is written
\[ A_{\text{QCD}} = \epsilon_{\rho_1}(k_1) \cdots \epsilon_{\rho_N}(k_N) T^{\mu_1 \cdots \mu_M}_{a_1 \cdots a_N; b_1 \cdots b_M} \epsilon_{\mu_1}(k_1) \cdots \epsilon_{\mu_M}(k_M) \]
(22)
then one gets zero if any number, $\geq 1$, of the polarization vectors $\epsilon_{\rho_i}(k_j)$ and/or $\epsilon_{\rho_i}(k_j)$ are replaced by $k_j$, $\mu_j$ and/or $\nu_j$, $\nu_i$, respectively, provided that all these $k_j$’s and $\kappa_j$’s, with the exception of at most one of them , satisfy $k_j^2 = 0$ and $\kappa_j^2 = 0$.

If we take into account Eq. (21) and introduce the function
\[ \Pi(Q^2, k^2, k q_1, k q_2) = (-g^{\mu \nu}) \delta_{ab} \Pi^{ab}_{\mu \nu}(Q^2, k^2, k q_1, k q_2), \]
(23)
the final formula for the multiplicity will look as follows:
\[ N_{M+X_M}^R(Q^2) = n_M + N_{M}^g \]
(24)
\[ n_M + \int \frac{d^3k}{(2\pi)^3} \Pi(Q^2, k^2, k q_1, k q_2) \frac{d}{dp^2} N_g(p^2) \]
Concrete form of the function $\Pi$ for different processes can be found in Appendices B,C.

### 3 Numerical results of calculations

In this section we consider numerical results for average charged multiplicities in different processes of top production at the LHC. Below we consider the phase space when final jets have low transverse momentum cuts $P_t$, and the final gluon jet can not be experimentally separated from one of final quark jets (i.e. gluon jet lies within the cone $\cos \theta_{qg} > R = 0.9$, where $\theta_{qg} < 0.45$ is the angle between the gluon and quark jets).

Let us begin with the inclusive $t \bar{t}$ production [2]. The total cross-section of the inclusive process $pp \rightarrow t \bar{t} + X$ is about 833 pb at 14 TeV. In this article we consider only the gluon-gluon fusion mechanism of this process since at LHC it is dominant. Numerical values for $N_{M}^g$ are given in the Table 1 and on the Fig. 2. Here and below theoretical errors are estimated by the use of two different parametrizations [17,18] for the hadronic multiplicity in a gluon jet. The average charged multiplicity in different decay modes (hadronic, semileptonic and leptonic) can be calculated as follows

\[ N_{t\bar{t}\rightarrow hadrons}^h(Q) = 2 n_t^h + N_{t\bar{t}}^g(Q), \]
(25)
\[ N_{t\bar{t}\rightarrow l+\bar{V}+hadrons}^h(Q) = n_t^h + n_{\bar{t}}^h + N_{t\bar{t}}^g(Q), \]
(26)
\[ N_{t\bar{t}\rightarrow l+\bar{V}+hadrons}^h(Q) = 2 n_t^h + N_{t\bar{t}}^g(Q). \]
(27)
As you see on the Fig. 2 the dependence of $N_{M}^g$ on the energy is visible. In this work we assume that color reconnection of $t\bar{t}$ and beam remnants is small due to the

| $N_{M}^g(Q,P_t)$ | $Q$, GeV | $P_t$, GeV |
|-----------------|---------|-----------|
| $600$           | $2.82 \pm 0.07$ | $2.89 \pm 0.2$ | $15.75 \pm 0.36$ |
| $1000$          | $0.76 \pm 0.02$ | $2.96 \pm 0.06$ | $6.58 \pm 0.12$ |
| $1500$          | $0.4 \pm 0.01$ | $1.3 \pm 0.02$ | $3.63 \pm 0.05$ |
strong suppression of these processes with high transverse momentum transfer (typical jet transverse momentum cut at the LHC is about 20-40 GeV). Also $t$ and $t$ fragment independently after the interaction inside the $tt$ system. It looks similar to the process of $W^+W^-$ fragmentation in $e^+e^-$ annihilation. The effect of possible color reconnection was investigated by comparing hadronic multiplicities in $e^+e^- \rightarrow W^+W^- \rightarrow qq'q''$ and $e^+e^- \rightarrow W^+W^- \rightarrow q\bar{q}l\bar{l}$. No evidence for final state interactions was found by measuring the difference $<n_{tg}^h>-2<n_{tg}^{\text{bare}}>$ [18]. The values for average charged multiplicities can be compared with the present LHC data on the inclusive $tt$ production.

The case of s-channel single top production [3] is close to the $e^+e^-$ one, since the final state is a result of $W$ decay, i.e. color singlet. That is why we have no color reconnection with beam remnants. However, the cross-section of this process is rather small (about 11 pb at 14 TeV), and the experimental task on the extraction of the multiplicity looks more difficult than, for example, in t-channel single top or $tt$ production. Numerical values for $N_{tg}^h$ are given in the table 2 and on the Fig. 3. The average charged multiplicity in different decay modes looks as follows

$$N_{th}\rightarrow\text{hadrons}^h(Q)=n_t^H+n_b+N_{tg}^h(Q),$$  \hspace{1cm} (28)  
$$N_{th}\rightarrow\ell\bar{\ell}\rightarrow\text{hadrons}^h(Q)=n_t^L+n_b+N_{tg}^h(Q).$$  \hspace{1cm} (29)  

The energy dependence is not so strong as in the previous case (see Fig. 4).

**Table 2.** S-channel single top production. Multiplicity $N_{tb}^q$ for different cuts of jet transverse momenta $P_t$ and the energy of parton-parton collision.

| $P_t$, GeV | 600  | 1000 | 1500 |
|------------|------|------|------|
| 10         | 11.2±0.32 | 14.8±0.41 | 18.7±0.5 |
| 30         | 6.55±0.19  | 10±0.27  | 13.2±0.33 |
| 50         | 4.33±0.12  | 7.55±0.2  | 10.4±0.25 |

The process of t-channel single top production $pp \rightarrow t+X$ has higher rate (about 245 pb at 14 TeV) than the previous one, but we have to make the same assumptions concerning fragmentation and color reconnection processes as in $tt$ production. Here calculations for the parton level process [4] are presented. Numerical values for $N_{tg}^h$ are given in the table 3 and on the Fig. 4. The average charged multiplicity in different decay modes looks as follows

$$N_{tg}^h\rightarrow\text{hadrons}^h(Q)=n_t^H+n_q+N_{tg}^h(Q),$$  \hspace{1cm} (30)  
$$N_{tg}^h\rightarrow\ell\bar{\ell}\rightarrow\text{hadrons}^h(Q)=n_t^L+n_q+N_{tg}^h(Q).$$  \hspace{1cm} (31)  

As you can see on the Fig. 4 the value of $N_{tg}^h$ is rather

**Table 3.** T-channel single top production. Multiplicity $N_{tg}^h$ for different cuts of jet transverse momenta $P_t$ and the energy of parton-parton collision.

| $N_{tg}^h(Q, P_t)$ | $Q$, GeV |
|---------------------|----------|
| 600                 | 1000     | 1500     |
| 10                  | 6.23±0.18 | 7.65±0.22 | 8.62±0.24 |
| 30                  | 2.4±0.07  | 2.77±0.075 | 3.29±0.08 |
| 50                  | 1.32±0.08 | 1.59±0.04 | 1.76±0.044 |

**Fig. 2.** $tt$ production. Multiplicity $N_{tb}^q$ versus $Q$ for different cuts of jet transverse momenta. Top-down: $P_t=10$ GeV $\rightarrow P_t=30$ GeV $\rightarrow P_t=50$ GeV.

**Fig. 3.** S-channel single top production. Multiplicity $N_{tg}^h(Q)$ versus $Q$ for different cuts of jet transverse momenta. Top-down: $P_t=10$ GeV $\rightarrow P_t=30$ GeV $\rightarrow P_t=50$ GeV.

**Fig. 4.** T-channel single top production. Multiplicity $N_{tg}^h(Q)$ versus $Q$ for different cuts of jet transverse momenta. Top-down: $P_t=10$ GeV $\rightarrow P_t=30$ GeV $\rightarrow P_t=50$ GeV.
small in the wide kinematical region, and energy dependence is not strong. It is important for the estimation of the multiplicity from beam remnants plus color reconnection effects, since values $n^H_t$, $n^L_t$, $n_q$ are fixed by previous measurements and $N^q_{tW}(Q) \ll n_t$. From this point of view the t-channel single top production looks the most interesting process for the multiplicity measurements.

$tW$ production has intermediate cross-section of the order 62 pb at 14 TeV which lies between s- and t-channel single top production rates. Probably, specific signature of this process would help in the measurements proposed in this work. Numerical values for $N^q_{tW}$ are given in the table on the Fig. The process has 3 decay modes. The corresponding average charged multiplicities are

\begin{align*}
N^h_{tW \to \text{hadrons}}(Q) &= n^H_t + n_W + N^q_{tW}(Q), \quad (32) \\
N^h_{tW \to (W)l\bar{\nu} + \text{hadrons}}(Q) &= n^H_t + N^g_{tW}(Q), \quad (33) \\
N^h_{tW \to t^+ t^- \nu\bar{\nu} + \text{hadrons}}(Q) &= n^L_t + N^g_{tW}(Q). \quad (34)
\end{align*}

The energy dependence is also visible and can be used to test QCD calculations.

4 Discussions and conclusions

In this article we consider four processes with top production at the LHC. Average charged hadronic multiplicities were calculated in perturbative QCD. Hadronic multiplicity in a gluon is fixed by low energy data.

There are several important tasks that could be solved by multiplicity measurements: to test QCD calculations independently on fragmentation models, to check independent fragmentation of heavy quarks, to check parton-parton C.M. energy dependence of hadron multiplicities, to estimate multiplicity from beam remnants plus from color reconnection effects in t-channel single top for further use in other processes. We can calculate also the difference $\Delta N_{Qq} \equiv N_Q - N_t$ to cancel effects of color reconnection and beam remnants.

There are several assumptions in the present work:

- independent fragmentation of on-shell top quarks in $t\bar{t}$ production;
- color reconnection effects in the interaction of jets with beam remnants (for nonsinglet production of $t\bar{t}$, $tq'$, $tW$) are suppressed for large lower cuts in jet transverse momenta. As you can see on the Fig. the fragmentation pattern in $t\bar{t}$ production is rather complicated. We have beam remnants with low transverse momentum interacting with jet remnants with large transverse momenta. Amplitudes for such processes are suppressed for high $P_t$ since they are proportional to the inverse power of the momentum transfer squared $\hat{s}$ in the parton-parton interaction, and

\begin{align*}
\hat{s} &= (p^0_0 - p^0_{\text{jet}})^2 - (p^3_{\text{beam}} - p^3_{\text{jet}})^2 - \\
&= (p^0_1 - p^0_{\text{jet}})^2 \simeq -p^0_{\text{jet}}^2 < -p^0_t^2,
\end{align*}

where $p^0_{\text{beam}}$ and $p^0_{\text{jet}}$ are momenta of beam and jet partons correspondingly, and from the kinematics

$p^0_0 \sim |p^0_{\text{beam}}| \gg p^0_{\text{jet}} \sim |p^0_{\text{jet}}|, p^0_{\text{jet}} \gg p^0_1$.

Fig. 5. Multiplicity $N^q_{tW}(Q)$ versus $Q$ for different cuts of jet transverse momenta. Top-down: $P_t = 10$ GeV $\rightarrow$ $P_t = 30$ GeV $\rightarrow$ $P_t = 50$ GeV.

Fig. 6. Complicated fragmentation pattern of the inclusive $t\bar{t}$ production in pp collisions. a) beam remnants; b) hadrons arising from the color interaction of beam remnants with the final state radiation from quarks (suppressed for high-$P_t$ of final quarks or gluons); c) hadrons from top fragmentation; d) result of $t^+\bar{t}^-$ interaction.
We are interested only in c and d types of fragmentation depicted on the Fig.\textsuperscript{[1]} in the s-channel $t\bar{b}$ singlet production there is no color reconnection with beam remnants.

All the above assumptions are based on low energy data and theoretical estimations of pQCD and also can be checked at the LHC.

From the experimental point of view t-channel single top production\textsuperscript{[2]} is the most convenient case, since the energy dependence of the average charged hadronic multiplicity is weak. We can estimate quantitatively effect of color reconnection of jets with beam remnants to check our assumption on its suppression. Then we can use this estimation to improve our predictions for other channels of top production. For this task it is also useful to extract multiplicities in different decay modes of top quarks.

The final experimental task is to extract number of tracks in jets which are produced in top quark decays. To estimate experimental efficiencies and dependence on a fragmentation model we can use any MC generator for top production. At the same time with the top-mass reconstruction model we can use any MC generator for tracks in jets which are produced in top quark decays.

Appendix A

Let us consider the process

\[ \text{parton}_1(q_1) + \text{parton}_2(q_2) \to c(p_1) + d(p_2) + g(k) \]  

and put $q_1^2 = 0, k^2 = K^2 > 0$ (we put also $m_b = 0$ for processes\textsuperscript{[3],[4]}, since corrections are of the order $m_b^2/m_t^2 \ll 1$). In the C.M. frame of colliding partons we can write:

\[ q_1 = \frac{Q}{2} (1, 0, 0, 1), \quad q_2 = \frac{Q}{2} (1, 0, 0, -1), \]
\[ q = q_1 + q_2, \quad A = (q_1 - q_2)/2, \]
\[ k = \left( \frac{q_k}{Q}, \frac{\sqrt{D}}{Q} \sin \theta_k, 0, \frac{\sqrt{D}}{Q} \cos \theta_k \right), \]
\[ l = \left( \frac{Q^2 + Z}{2Q}, |l| \sin \theta_l \cos \phi, |l| \sin \theta_l \sin \phi, |l| \cos \theta_l \right), \]
\[ p_1 = l - k, \quad p_2 = q - l, \]  

\[ D = (qk)^2 - Q^2 K^2, \quad |l| = \sqrt{\left( \frac{Q^2 - Z^2}{4Q^2} \right) - m_2^2}, \]
\[ s = (q - k)^2 = Q^2 + K^2 - 2q_k, \quad Z = l^2 - m_2^2, \]
\[ \cos \theta_{kl} = \cos \theta_l \cos \theta_k + \sin \theta_l \sin \theta_k \cos \phi \quad \text{or} \]
\[ \cos \theta_l = \cos \theta_{kl} \cos \theta_k + \sin \theta_{kl} \sin \theta_k \cos \phi^*. \]  

After change of variables phase space looks as follows:

\[ \int dK^2 \int d\Phi_{2 \to 3} = \int dK^2 \int d^4 k \int \frac{d^4 q}{(2\pi)^4} \times \]
\[ (2\pi)^4 \delta(p_1^2 - m_t^2)(2\pi)^4 \delta(p_2^2 - m_2^2)(2\pi)^4 \delta(K^2 - k_k k^\mu) = \]
\[ \left[ \frac{\sqrt{D}}{2(2\pi)^2 Q^2} \right] \delta(\mathcal{H}(Z)) \int dK^2 \int dZ \int d\phi \int d\cos \theta_k d\cos \theta_l = \]
\[ \frac{1}{2(4\pi)^4 Q^2} \int \frac{K^2}{(q_k)_+ C_{k,+}} \int \frac{d\cos \theta_k}{C_{k,-}} \int \frac{dZ}{Z} \int \frac{d\phi}{\pi}, \quad \mathcal{H}(Z) = \cos \theta_{kl}(Z) - \cos \theta_k \cos \theta_l - \sin \theta_k \sin \theta_l \cos \phi. \]  

Here we keep the integration in $K^2$ since the gluon is virtual.

Then we have to cut jet transverse momenta from below to suppress color reconnection with beam remnants

\[ p_{i,\perp} \geq P_{t,i}, \quad k \perp \geq K, \]

or

\[ p_{i,3} \leq \sqrt{P_{t,i}^2 - P_{t,1}^2}, \quad k \leq \sqrt{K^2 - K_t^2}. \]  

In this paper $K_t = P_{t,1}$. Finally we have conditions

\[ |\cos \theta_l| |l| \leq \sqrt{L^2 - P_{t,1}^2}, \]  

\[ |l| \cos \theta_l - |k| \cos \theta_k \leq \sqrt{(l - k)^2 - P_{t,1}^2}. \]  

For limits in the above integrals without conditions\textsuperscript{[5],[6]} we can write

\[ K_t^2 = Q_0^2, \quad K_t^2 = \left( Q - \sqrt{(m_1 + m_2)^2 + K_t^2} \right)^2 - K_l^2, \]
\[ (qk)_- = Q \sqrt{K^2 + K_l^2}, \]
\[ (qk)_+ = \frac{Q^2 + K^2 - (m_1 + m_2)^2}{2}, \]
\[ m_{i,\perp} = \sqrt{m_t^2 + P_i^2}, \]
\[ C_{k,\pm} = \pm \sqrt{D - Q^2 K_t^2}, \]
\[ Q \geq \sqrt{(m_1 + m_2)^2 + K_t^2} + \sqrt{Q_0^2 + K_t^2} > m_1 + m_2 + Q_0, \]
\[ Q \leq x_{i,\max} \sqrt{s}. \]  

Taking into account the inequality \( \cos \theta_{kl} \) can be obtained from $\delta((k - l)^2 - m_l^2)$

\[ |\cos \theta_{kl}| = \left| \frac{A_i}{Q^2 |l|} \right| \leq 1, \]  

where
For multidimensional integration it is convenient to introduce the following conditions:

\[ Z_\pm = q_k + \left( \frac{Q^2 - q_k(m_1^2 - m_2^2)}{s} \right) \pm \sqrt{D} \sqrt{D_{12}(s, m_1, m_2)}, \]

where \( s \) is the square of the center-of-mass energy. The above inequality leads to the following conditions:

\[ D_{12}(s, m_1, m_2) = \left( 1 - \frac{(m_1 + m_2)^2}{s} \right) \left( 1 - \frac{(m_1 - m_2)^2}{s} \right). \]

For multidimensional integration it is convenient to introduce unidimensional variables and make appropriate symmetrization of the function under the integration:

\[ \phi = x_0 \pi, \quad x_0 \in [0, 1], \]
\[ Z = q_k + \left( \frac{Q^2 - q_k(m_1^2 - m_2^2)}{s} \right) + \zeta \sqrt{D} \sqrt{D_{12}(s, m_1, m_2)}, \quad \zeta \in [-1, 1], \]
\[ \cos \theta_k = \tau \sqrt{\frac{D - Q^2 K_2^2}{D}}, \quad \tau \in [-1, 1], \]
\[ q_k = (q_k)_+ \eta ((q_k)_+ - (q_k)_-), \quad \eta \in [0, 1], \]

\[ \int d(qk) \ d \cos \theta_k \ dZ \ d\phi (q_k, \cos \theta_k, Z, \phi) = \left. \int d\eta \ d\tau \ d\zeta \ d\eta \right| \]
\[ D \tilde{f}^{sym}, \quad \tilde{f}^{sym} = \tilde{f}(\eta, \tau, \zeta, x_0) + \tilde{f}(\eta, -\tau, -\zeta, x_0) + \tilde{f}(\eta, -\tau, \zeta, x_0) + \tilde{f}(\eta, \tau, -\zeta, x_0), \quad D = ((q_k)_+ - (q_k)_-) \times \]
\[ \sqrt{D - Q^2 K_2^2} \sqrt{D_{12}(s, m_1, m_2)}, \]

where \( \tilde{f} \) is equal to \( f \) after the change of variables.

In this paper we consider the case, when the final gluon jet can not be separated experimentally from one of final quark jets:

\[ \cos \theta_{gq} > R = 0.9, \quad \text{or} \quad \theta_{gq} < 0.45. \]

The above inequality leads to the following conditions:

\[ \cos \theta_{P_k} = - \cos \theta_k > R, \quad \text{(51)} \]
\[ \text{or} \quad \cos \theta_{P_k} = - \cos \theta_{k|\zeta - \zeta} > R, \quad \text{(52)} \]

where \( \cos \theta_k \) is expressed in terms of variables \( \zeta, \eta, x_0, \tau \).

Let us denote conditions (51, 52) as a product of corresponding angular functions:

\[ f_{T,R} = \theta \left( \sqrt{P^2 - P^2_{l_1} - \cos \theta_k} \right) \times \theta \left( \sqrt{(l - k)^2 - P^2_{l_1} - \cos \theta_k} \right) \times \]
\[ \left[ \theta (\cos \theta_k - R) \text{ or } \theta (\cos \theta_k|\zeta - \zeta - R) \right], \quad \text{(53)} \]

where

\[ \theta(x) = \begin{cases} 1, & x \geq 0 \\ 0, & x < 0 \end{cases}. \]

Now we can rewrite the second term in the r.h.s. of Ref. (24) as follows:

\[ \int \frac{d^3k}{(2\pi)^3} \frac{d\theta}{d^2p_{\perp}} N_s(p^2) \left|_{p^2 = k^2} \right. = I_1, \quad \text{(54)} \]
\[ I_1 = \frac{1}{2 \pi^2} \int dK^2 \alpha_s(k^2) \frac{d\theta}{d^2p_{\perp}} N_s(p^2) \left|_{p^2 = K^2} \right. \]
\[ \int \frac{d\theta}{d^2p_{\perp}} f_{T,R} \tilde{f}_{\gamma \rightarrow 3}, \quad \text{(55)} \]
\[ I_2 = \int \frac{d\theta}{d^2p_{\perp}} f_{T,R} \tilde{f}_{\gamma \rightarrow 2}, \quad \text{(56)} \]
\[ C_\gamma = \frac{D_{12}(Q^2, m_{1,2})}{D_{12}(Q^2, m_{1,2})}, \quad \text{(57)} \]

where \( \tilde{f}_{\gamma \rightarrow 3} \) is the amplitude squared of the corresponding process 2 with (without) gluon radiation, which is calculated in Appendices B, C. For simplicity we put all the coupling constants to unity in these quantities. Here \( g_s = \sqrt{4\pi\alpha_s} \) is the QCD coupling constant. All tensors are contracted as in (10) and (24).

Different kinematical invariants of the process \( 3 \) can be expressed in terms of \( Q^2, K^2, q_k, \cos \theta_k, Z, \phi \) (and then \( Q^2, K^2, \eta, \tau, \zeta, x_0, \phi \)):
Here we consider amplitudes for the top-antitop production $R.A. Ryutin: Hadron multiplicity induced by top quark decays at the LHC.$

Fig. 7. Amplitudes of the process $gg \rightarrow QQ.$

Fig. 8. $gggQ\bar{Q}$ amplitudes.

$$A_1^\lambda = \frac{q^2 - qk}{4} \sqrt{D_{12}(s, m_{1, \perp}, m_{2, \perp})} = \frac{\sqrt{D}}{4} \left(1 - \frac{m_1^2 - m_2^2}{s}\right),$$

$$B_l = \frac{\sqrt{2}}{4} \sqrt{2} A_l^2 = \frac{Q}{4} \sqrt{D_{12}(s, m_{1, \perp}, m_{2, \perp})} \sqrt{1 - \zeta^2}. \quad (59)$$

Appendix B

Here we consider amplitudes for the top-antitop production $\{3\}.$ For the amplitude of the process without additional gluon radiation we have three diagrams of Fig. 7 and $I_2$ can be calculated as follows

$$I_2 = \frac{8}{3 \pi} \left\{ 8(1 + x_m^4 + x_m^6) \ln \frac{1 + x_m^4}{2x_m} + \sqrt{1 - 4x_m^2} \left(3x_m^2 - 18x_m^2 - 7 - 16x_m^4 \right) \right\}, \quad (60)$$

where we consider all gluons as initial particles. Then we can calculate

$$T_{2 \rightarrow 3}^{a_1 a_2 a_3 a_4} (q_1, q_2, q_3) = \left\{ A_1^{123} + A_1^{123} + A_1^{131} + A_1^{132} + A_1^{131} + A_1^{123} \right\}, \quad (64)$$

Here $q_3 = -k$ since we have one gluon in the final state with momentum $k$, $A_1^{123} \equiv \bar{A}_{1, \rho_1 \rho_2 \rho_3}^{a_1 a_2 a_3}(q_1, q_2, q_3, p_{1,2}, [i j k] = \epsilon^{i j k} \epsilon^{\alpha \beta \gamma} \epsilon^{\rho \sigma \tau}, \epsilon^{\alpha \beta \gamma} \text{are SU}(3) \text{ matrices}, u \text{ and } v \text{ are Dirac spinors, } \gamma_\rho \text{ are Dirac matrices, } p \equiv p^{\mu} \gamma_\mu$. If we apply contractions $\{10\}, \{20\}$ to $\{55\}$ and take into account the theorem $\{22\}$ (it was checked by direct calculations for $\{51\}$) then we obtain $g_5^3 \bar{H}_{2 \rightarrow 3}$ for the process $\{3\}.$ Since the final expression for $\bar{H}_{2 \rightarrow 3}$ is very complicated, we evaluate it numerically. To get the final result for the $tt$ multiplicity induced by gluon radiation ($N_{tt}^g$ on the Fig. 1b) we have to substitute $I_2$ and $\bar{H}_{2 \rightarrow 3}$ for this process to $\{54\} - \{55\}$.

Appendix C

For simplicity here we set all coupling constants to unity. In this section we consider calculations for processes $\{3\}$ - $\{5\}$.

Let us introduce some functions for further calculations. One of the functions is the $WQq$ vertex squared (see Fig. 9a)

$$A_{\alpha} = \bar{u}(p_2, m_2)\gamma_\alpha(1 - \gamma_5)v(p_1, m_1), \quad (66)$$
Fig. 9. Amplitudes for calculation of functions $\mathcal{F}^{(0)}$ (a) and $\mathcal{F}^{(1)}$ (b).

$$
\mathcal{F}^{(0)}_{\alpha \alpha'}(p_1, m_1, p_2, m_2) = C_A A^{(0)}_{\alpha} A^{(0)\ast}_{\alpha'} = 8 C_A \left( g_{\alpha \alpha'} p_1 p_2 - p_1 \, p_2 \alpha - p_2 \, p_1 \alpha - i \epsilon_{\alpha \alpha' \sigma} p_1 p_2 \sigma \right),
$$

(67)

The next one is the squared amplitude of the process $W \to Q\bar{q}g$ which is shown on the Fig. [3].

$$
A^{(1)}_{\alpha \mu} = \bar{u}(p_2, m_2) \left\{ \frac{\gamma_\mu (1 - \gamma_5) (-\bar{p}_1 - \bar{k} + m_1)}{K^2 + 2 p_1 k} + \frac{\gamma_\mu \left( \bar{p}_2 + \bar{k} + m_2 \right) \gamma_\alpha (1 - \gamma_5)}{K^2 + 2 p_2 k} \right\} v(p_1, m_1),
$$

(68)

$$
\mathcal{F}^{(1)}_{\alpha \alpha' \mu \mu'}(p_1, m_1, p_2, m_2, k, K) = C_A C_F A^{(1)}_{\alpha \mu} A^{(1)\ast}_{\alpha' \mu'},
$$

(69)

$$
\mathcal{F}^{(1)}_{\alpha \alpha' \mu \mu'}(p_1, m_1, p_2, 0, k, K) = \frac{128}{(K^2 + 2 p_1 k)^2 (K^2 + 2 p_2 k)^2} \sum_{i=1}^{9} \mathcal{F}^{(1)}_{\alpha \alpha'},
$$

(70)

where

$$
\mathcal{F}^{(1)}_{\alpha \alpha'} = g_{\alpha \alpha'} \times
$$

$$
\left\{ Q^4 \left[ Z(2qk - Z) + 2m^2(Z - qk) - m^4 \right] + Q^2 \left[ -2K^2 (m^2 + qk - Z)^2 - 2qk(2qk - Z)Z - m^2(4qk - Z) + 2m^4(qk - Z) + m^6 \right] + K^2 m^2 [2qk^2 - 2Z qk + Z^2 + 2m^2(qk - Z) + m^4] + Z(2qk - Z)(2qk - 2Z qk + Z^2) + 2m^2(-2qk^2 + 8qk^2 Z - 7Z^2 qk + 2Z^2) + 2m^4(-3qk^2 + 7Z qk - 3Z^2 - 4m^6(qk - Z) - m^8) \right\},
$$

(71)

$$
\mathcal{F}^{(1)\ast}_{\alpha \alpha'} = \frac{p_1 \alpha p_1 \alpha'}{\bar{p}_1 \alpha p_1 \alpha'},
$$

$$
\left\{ K^2 \left[ -Z(2qk - Z) + 2m^2(qk - Z) + m^4 \right] + Z(2qk - Z)^2 - m^2(4qk^2 - 8Z qk + 3Z^2) - m^4(4qk - 3Z) - m^6 \right\},
$$

(72)

$$
\mathcal{F}^{(1)}_{\alpha \alpha'} = \frac{p_2 \alpha p_2 \alpha'}{\bar{p}_2 \alpha p_2 \alpha'},
$$

$$
\left\{ K^2 \left[ -Z(2qk - Z) + 2m^2(qk - Z) + m^4 \right] + Z^2(2qk - Z) - m^2(4qk - 3Z) + m^4(2qk - 3Z) + m^6 \right\},
$$

(73)

$$
\mathcal{F}^{(1)\ast}_{\alpha \alpha'} = (p_1 \alpha p_2 \alpha' + p_2 \alpha p_1 \alpha') \times
$$

$$
\left\{ Q^2 \left[ -Z(2qk - Z) + 2m^2(qk - Z) + m^4 \right] + K^2 \left[-Z(2qk - Z) + 2m^2(qk - Z) + m^4 + 2qk^2 \right] + qk(2qk - Z)Z + 2m^2qk + m^4qk \right\},
$$

(74)

$$
\mathcal{F}^{(1)}_{\alpha \alpha'} = \frac{p_1 \alpha k_{\alpha'} + k_{\alpha} p_1 \alpha'}{\bar{p}_1 \alpha k_{\alpha'} + k_{\alpha} \bar{p}_1 \alpha'},
$$

$$
\left\{ \frac{Q^2}{2} \left[ -Z(2qk - Z) + 2m^2(qk - Z) + m^4 \right] + K^2 \left[ -Z(qk - Z) + m^2(qk - 2Z) + m^4 \right] + \frac{1}{2} Z(2qk - Z)^2 - m^2(qk - 2Z)(2qk - Z) - \frac{m^4}{2}(6qk - 5Z) - m^6 \right\},
$$

(75)

$$
\mathcal{F}^{(1)\ast}_{\alpha \alpha'} = (p_2 \alpha k_{\alpha'} + k_{\alpha} p_2 \alpha') \times
$$

$$
\left\{ \frac{Q^2}{2} \left[ -Z(2qk - Z) + 2m^2(qk - Z) + m^4 \right] + K^2 \left[ 2qk^2 - 3Z qk + Z^2 + m^2(3qk - 2Z) + m^4 \right] + \frac{1}{2} Z(2qk - Z)^2 + m^2(4qk^2 - 5Z qk + 2Z^2) - \frac{m^4}{2}(8qk - 5Z) + m^6 \right\},
$$

(76)

$$
\mathcal{F}^{(1)}_{\alpha \alpha'} = \frac{\epsilon_{\alpha \alpha' \rho \sigma} p_1^\rho p_2^\sigma}{\bar{p}_1 \alpha p_2 \alpha'},
$$

$$
\left\{ Q^2 \left[ -Z(2qk - Z) + 2m^2(qk - Z) + m^4 \right] + K^2 \left[ 2qk^2 - 3Z qk + Z^2 + m^2(3qk - 2Z) + m^4 \right] + Z(2qk - Z)(qk - Z) + m^2(2qk^2 + 4Z qk - 3Z^2) + m^4(3Z - qk) - m^6 \right\},
$$

(77)

$$
\mathcal{F}^{(1)\ast}_{\alpha \alpha'} = i (\epsilon_{\alpha \rho \sigma \lambda} p_1^\rho p_2^\sigma - \epsilon_{\alpha' \rho \sigma \lambda} p_1^\rho p_2^\sigma),
$$

(78)

$$
\mathcal{P}_\alpha = (k - p_1 + p_2)_\alpha \left( Z^2 - 2Z + m^4 \right) + 2qk(Z - m^2)p_1 \alpha,
$$

(79)
\[ F^{(1)}_{\alpha \alpha'} = \delta_{\alpha \alpha'} \delta^{ab} \gamma^b \gamma^a \times \left\{ Q^2 \left[ -Z(qk - Z) + m^2(qk - 2Z) + m^4 \right] + K^2 \left[ 2gk^2 - 3Z qk + Z^2 + m^2(3qk - 2Z) + m^4 \right] + m^2 \left[ 4gk^2 - Z qk - Z^2 + m^2(qk + 2Z) - m^4 \right] \right\} \]

\[ Z \equiv l^2 = (p_1 + k)^2 = (q - p_2)^2, \quad m = m_t. \]

And the last one is the amplitude squared of the process which is depicted in the lower Fig. 11.

\[ F^{(2)}_{\alpha \alpha', \mu \nu', \rho \sigma'} (p_1, m_1, q_1, m'_1, q_2, m'_2, k, K) = \left( \sum_{i=1}^{s} \tilde{A}^{(2)i}_{\alpha \alpha' \mu \nu' \rho \sigma'} \right) \left( \sum_{j=1}^{s} \tilde{A}^{(2)j}_{\alpha \alpha' \mu \nu' \rho \sigma'} \right)^*, \quad p_2^2 = m_W^2. \] (81)

Here \( C_A = N = 3 \) and \( C_F = (N^2 - 1)/(2N) = 4/3 \) are structure constants of the group SU(3), color indices are contracted with \( \delta_{\mu \nu} \delta_{\rho \sigma} \) in (81). Expressions for Feynman diagrams looks as follows

\[ \tilde{A}^{(2)i}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \bar{v}(q_2, m'_2) \tilde{A}^{(2)i}_{\alpha \alpha' \mu \nu' \rho \sigma'} v(p_1, m_1), \]

\[ \tilde{A}^{(2)1}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \gamma_\rho \left( \bar{q} \gamma_a (1 - \gamma_5) \right) \left( \bar{p}_1 - \bar{k} + m_1 \right) \gamma_\mu \gamma^b \gamma^a \gamma^b, \]

\[ \tilde{A}^{(2)2}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \frac{\gamma_\rho (-\bar{q} + m'_2) \gamma_\alpha (1 - \gamma_5) \left( \bar{p}_1 - \bar{k} + m_1 \right) \gamma_\mu \gamma^b \gamma^a \gamma^b}{(Q^2 - m'_2^2) (K^2 - 2p_1 k)}, \]

\[ \tilde{A}^{(2)3}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \frac{\gamma_\rho \left( \bar{q} - \bar{k} + m'_2 \right) \gamma_\alpha (1 - \gamma_5) \gamma_\mu (1 - \gamma_5)}{(q_1 - k)^2 \left( q - k - m_2 \right)^2} \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho, \]

\[ \tilde{A}^{(2)4}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \frac{\gamma_\rho \left( \bar{q} - \bar{k} + m'_2 \right) \gamma_\alpha (1 - \gamma_5) \gamma_\mu (1 - \gamma_5)}{(q_2 - k)^2 \left( q - k - m'_2 \right)^2} \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho. \]

\[ A^{(2)5}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \gamma_\alpha (1 - \gamma_5) \left( \bar{p}_2 - \bar{q}_2 + m_1 \right) \gamma_\mu \left( \bar{p}_1 - \bar{k} + m_1 \right) \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho, \]

\[ A^{(2)6}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \frac{\gamma_\alpha (1 - \gamma_5) \left( \bar{p}_2 - \bar{q}_2 + m_1 \right) \gamma_\mu \left( \bar{q}_1 - \bar{p}_1 + m_1 \right) \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho}{(q_1 - k)^2 \left( p_2 - q_2 \right)^2 \left( p_1 - q_1 \right)^2}, \]

\[ A^{(2)7}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \frac{\gamma_\alpha (1 - \gamma_5) \left( \bar{q}_2 - \bar{p}_2 + m_1 \right) \gamma_\mu \left( \bar{q}_1 - \bar{p}_1 + m_1 \right) \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho}{(p_2 - q_2)^2 - m_1^2} \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho, \]

\[ A^{(2)8}_{\alpha \alpha' \mu \nu' \rho \sigma'} = \frac{\gamma_\alpha \left( \bar{q}_2 - \bar{p}_2 + m_1 \right) \gamma_\mu \left( \bar{q}_1 - \bar{p}_1 + m_1 \right) \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho}{(k^2 - q_2)^2 - m_1^2}, \]

\[ \left( (k^2 - q_2)^2 - m_1^2 \right) \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\sigma \gamma_\nu \gamma_\rho \gamma_\alpha \gamma_\mu \gamma_\sigma \gamma_\nu \gamma_\rho, \]

Now we have all the ingredients to calculate amplitudes of processes (3). At first let us consider the s-channel single top production in Fig. 11. We have to calculate \( N_{W}^2 \).

From upper and lower diagrams of the Fig. 11, we have

\[ \tilde{H}_{2 \to 2} = d_{W}^{\alpha \beta} (q) d_{W}^{\alpha' \beta'} (q) F_{\alpha \alpha'}^{(0)} (q_1 - q_2, 0), \]

\[ I_2 = \frac{6}{D_{12}(Q^2, m_\perp, p_1)} \frac{1}{\pi} \frac{1 - s_m^2}{(1 - x_w^2)^2} \times \]

\[ (3 + C''^2 + (3 - C''^2) x_m^2), \]

\[ C''^2 = D_{12}(Q^2, m_\perp, p_1) / D_{12}(Q, m_t, 0), \]

\[ x_w = m_W / Q, \]

and

\[ \tilde{H}_{2 \to 3} = \left\{ d_{W}^{\alpha \beta} (q) d_{W}^{\alpha' \beta'} (q) F_{\alpha \alpha'}^{(0)} (q_1 - q_2, -q_2, 0) \times \right\} \]

\[ \tilde{F}_{\alpha \alpha'}^{(1)} (p_1, m_t, p_2, 0, k, K) + \]

\[ d_{W}^{\alpha \beta} (q - k) d_{W}^{\alpha' \beta'} (q - k) F_{\alpha \alpha'}^{(0)} (p_1, m_t, p_2, 0) \times \]

\[ \tilde{F}_{\alpha \alpha'}^{(1)} (-q_1, -q_2, 0, k, K) \}

\[ (82) \] correspondingly, where

\[ d_{W}^{\alpha \beta} (q) = d_{W}^{\alpha \beta} (q) / (q^2 - m_W^2), \]

\[ d_{W}^{\alpha \beta} (q) = -g^{\alpha \beta} + q^2 q^2 / q^2 \]
and for all the calculations we put $m_b = 0$ since $m_b/m_t \ll 1$.

For the process (4) and calculation of $N_{tq'}^9$ we have the following functions (see diagrams on the Fig. 12).

$$ \tilde{I}_{2\rightarrow2} = \tilde{d}_{W}^{\alpha\beta}(q_1 - p_1)\tilde{d}_{W}^{\alpha'\beta'}(q_1 - p_1) \times \tilde{F}^{(0)}_{\alpha\alpha'}(p_2, 0, -q_2, 0)\tilde{F}^{(0)}_{\beta\beta'}(p_1, m_t, -q_1, 0), \quad (87) $$

$$ I_2 = \frac{288\sqrt{D_{12}(Q^2, m_t \perp, m_W \perp)}}{\pi} \times \frac{1 - x_m^2}{(1 - x_m^2 + 2x_m^2 - C'^2(1 - x_m^2)^2)}, \quad (88) $$

where $C'$ is the same as in the previous process.

$$ \tilde{I}_{2\rightarrow3} = \left\{ \begin{array}{l} d_{W}^{\alpha\beta}(q_2 - p_2)d_{W}^{\alpha'\beta'}(q_2 - p_2) \times \tilde{F}^{(0)}_{\alpha\alpha'}(p_2, 0, -q_2, 0)\tilde{F}^{(1)}_{\beta\beta'}(p_1, m_t, -q_1, 0, k, K) + d_{W}^{\alpha}(q_1 - p_1)d_{W}^{\alpha'\beta'}(q_1 - p_1) \times \tilde{F}^{(0)}_{\beta\beta'}(p_1, m_t, -q_1, 0)\tilde{F}^{(1)}_{\alpha\alpha'}(p_2, 0, -q_2, 0, k, K) \end{array} \right\}, \quad (89) $$

Calculations for the process (5) and $N_{tW}^{9}$ looks as follows (see diagrams on the Fig. 12).

$$ \tilde{I}_{2\rightarrow2} = \tilde{d}_{W}^{\alpha\alpha'}(p_2) \bigg|_{p_2^2 = m_W^2} \tilde{d}_{W}^{\beta\beta'}(q_1, n) \bigg|_{n = \Delta} \times \tilde{F}^{(1)}_{\alpha\alpha'\beta\beta'}(p_1, m_t, -q_2, 0, -q_1, 0), \quad (90) $$

$$ I_2 = \frac{1}{\pi} \left\{ -2\sqrt{D_{12}(Q^2, m_t \perp, m_W \perp)} \times \left[ u^2 (1 - C'^2) + 2x_m^2u^2 (1 + C'^2 - u^2 (1 - C'^2)) + x_m^2u^2 (1 - u^2)^2 (1 - C'^2) \right]^{-1} \times \left[ (3 - 2u^2) (1 - C'^2) + x_m^2 \left( 3 (C'^2 + 3) - u^2 (C'^2 + 7) - 2u^4 (1 - C'^2) \right) + x_m^4 (1 - u^2) \left( 25 + 3C'^2 + u^2 (23C'^2 + 33) - 10u^4 (1 - C'^2) \right) + 3x_m^6 (1 + 2u^2) (1 - u^2)^3 (1 - C'^2) \right] + 4(1 + 2u^2)(1 + 2x_m^2(1 - u^2) + 2x_m^4(1 - u^2)^2) \times \ln \frac{1 + x_m^2(1 - u^2)}{1 + x_m^2(1 - u^2) - \sqrt{D_{12}(Q^2, m_t \perp, m_W \perp)}} \right\}, \quad (91) $$

where

$$ C'^2 = D_{12}(Q^2, m_t \perp, m_W \perp)/D_{12}(Q^2, m_t, m_W), $$

$$ u = m_W/m_t, \quad (92) $$

$$ \tilde{I}_{2\rightarrow3} = \left( -g^{\mu\nu'} + k^{\mu}k^{\nu'} K^2 \right) \times \tilde{d}_{W}^{\alpha\alpha'}(p_2) \bigg|_{p_2^2 = m_W^2} \tilde{d}_{W}^{\beta\beta'}(q_1, n) \bigg|_{n = \Delta} \times \tilde{F}^{(2)}_{\alpha\alpha'\mu\nu', \rho\rho'}(p_1, m_t, q_1, 0, q_2, 0, k, K). \quad (93) $$
