**ABSTRACT**

Vaccines could be the solution to the current SARS-CoV-2 outbreak. However, some studies have shown that the immunological memory only lasts three months. Thus, it is imperative to develop pharmacological treatments to cope with COVID-19. Here, the \textit{in silico} approach by molecular docking, dynamic simulations and quantum biochemistry revealed that ACE2-derived peptides strongly interact with the SARS-CoV-2 RBD domain of spike glycoprotein (S-RBD). ACE2-Dev-PepI, ACE2-Dev-PepII, ACE2-Dev-PepI and ACE2-Dev-PepIV complexed with S-RBD provoked alterations in the 3D structure of S-RBD, leading to disruption of the correct interaction with the ACE2 receptor, a pivotal step for SARS-CoV-2 infection. This wrong interaction between S-RBD and ACE2 could inhibit the entry of SARS-CoV-2 in cells, and thus virus replication and the establishment of COVID-19 disease. Therefore, we suggest that ACE2-derived peptides can interfere with recognition of ACE2 in human cells by SARS-CoV-2 \textit{in vivo}. Bioinformatic prediction showed that these peptides have no toxicity or allergenic potential. By using ACE2-derived peptides against SARS-CoV-2, this study points to opportunities for further \textit{in vivo} research on these peptides, seeking to discover new drugs and entirely new perspectives to treat COVID-19.

**ARTICLE HISTORY**

Received 13 October 2020
Accepted 29 December 2020

**KEYWORDS**

SARS-CoV-2 RBD; COVID-19; ACE2 receptor; ACE2-derived peptides

**1. Introduction**

Coronaviruses (CoVs) are enveloped and pleomorphic viruses belonging to the Coronaviridae family. They share a typical morphology with the non-segmented positive single-stranded RNA genome, estimated to have length of 30 Kb (Burrell et al., 2017; Peiris, 2012). The human-to-human spread of the coronaviruses is mainly by nose and mouth secretion droplets. These viruses cause disease that ranges from mild cold symptoms to atypically severe pneumonia, with many complications, resulting in death (Burrell et al., 2017).

The current pandemic caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has claimed many lives and threatened thousands worldwide. Coronavirus disease 2019 (COVID-19) is less lethal and by far more transmissible than the diseases caused by the viruses involved in other recent outbreaks, such as in 2002 by severe acute respiratory syndrome coronavirus (SARS-CoV) and Middle East respiratory syndrome coronavirus (MERS-CoV). A way to measure that is the case fatality rate (CFR) of each outbreak. The CRF of SARS-CoV, MERS-CoV and SARS-CoV-2 is, respectively, of 9.7, 34 and 1%, which indicates that SARS-CoV-2 is not one of the worst coronaviruses. However, its higher transmissibility has resulted in 10 million of infected people with 500 000 deaths, by far a larger number compared to other outbreaks (Andersen et al., 2020; Li et al., 2020; Song et al., 2019).

SARS-CoV-2 is close to SARS-CoV-1, sharing similarities accounting nearly 80% in the genome sequence. Additionally, both coronaviruses employ the same receptor-binding domain (RBD) in the spike glycoprotein (S protein) to interact with human angiotensin-converting enzyme 2 (ACE2) of the host cell to start the infection. The virus takes control of the cellular machinery to synthesize its own genome and proteins. Despite similarities, the SARS-CoV-2 S protein has accumulated mutations, leading to modifications in the RBD region that enhance its affinity for human ACE2 20-fold compared to SARS-CoV S protein, resulting in faster transmission from human to human (Andersen et al., 2020; Wallis et al., 2020; Yuan et al., 2017).

Despite the similarities, it is important to highlight the differences between SARS-CoV-1 and SARS-CoV-2 receptor recognition as they are involved in virus transmissibility, infectivity and pathology. It is known that the SARS-CoV-2 RBD has a higher ACE2-binding affinity than SARS-CoV-1, a characteristic which could lead to a more efficient cell entry and transmissibility (Wallis et al., 2020; Yan et al., 2020).
contrast, ACE2 affinity toward the entire SARS-CoV-2 S protein is lower than that of SARS-CoV entire S protein suggesting that SARS-CoV-2 RBD, besides being strongest, is probably less exposed than SARS-CoV RBD (Andersen et al., 2020; Song et al., 2019; Walls et al., 2020; Yan et al., 2020; Yuan et al., 2017). In addition, SARS-CoV-2 S protein also held substitution D614G during the coronavirus disease 2019 (COVID-19) pandemic (Sheffield COVID-19 Genomics Group, 2020). An elegant experiment using the cryoelectron microscopy (cryo-EM) revealed that the change from D614 to G614 eliminates the requirements of side-chain hydrogen bond, increasing mainchain flexibility and altering interactions, and modulates glycosylation enhancing the cell entry, infectivity, transmissibility, stability of virions and high viral loads in the airways (Sheffield COVID-19 Genomics Group, 2020; Wrapp et al., 2020). Besides these differences, a new feature is the high nanomechanical stability of the SARS-CoV-2 S-ACE2 interaction compared to SARS-CoV-1 (Moreira et al., 2020). Moreira et al. (2020) revealed that high mechanical stability in the SARS-CoV-2 S-ACE2 has several biological implications such as cell recognition, viral attachment, fusion and entry. Thus, mechanical stability might play a role in the increasing spread of COVID-19 (Moreira et al., 2020).

Still regarding the importance of S-ACE2 interaction for SARS-CoV-2 cell entry, there recently have been reported that mutations far from RBD could affect the S-ACE2 interaction (Qiao & Olvera de la Cruz, 2020). For example, Qiao and Olvera de la Cruz (2020) reported that altering the polybasic cleavage of SARS-CoV-2 Spike protein could result in 34% of the S-RBD strength of the interaction. This result suggests the role of polybasic cleavage in enhancement of S-ACE2 interaction (Qiao & Olvera de la Cruz, 2020).

Given the importance of the S-ACE2 interaction to COVID-19 establishment, many studies have focused on finding drugs (either already available or new ones) that can interfere with this interaction, making S protein a promising target in silico assays. Other groups have been investigating existing drugs used to treat other viral infections, in a process called repositioning or repurposing, but without success (Calligari et al., 2020). Nevertheless, computational screening is an exciting approach to develop new drugs faster and more precisely. Therefore, many research groups are employing molecular docking (MD) and molecular dynamic simulation (MDS) to find new molecules targeting the SARS-CoV-2 S protein (Calligari et al., 2020; Souza et al., 2020).

Recently, our research group performed MD and MDS studies using eight synthetic antimicrobial peptides (Mo-CBP3-PepI, Mo-CBP3-PepII, Mo-CBP3-PepIII, Rcab-PepI, Rcab-PepII, PEPGAT and PEPKAA) to target the SARS-CoV-2 S glycoprotein (Souza et al., 2020). Of those, Mo-CBP3-PepII and PEPKAA strongly interacted with the SARS-COV-2 S protein, changing its native conformation and topology, leading to wrong interaction with ACE2 (Souza et al., 2020).

The most crucial feature of the SARS-CoV-2 S protein is the high affinity of the RBD domain to the human ACE2 receptor, leading to higher levels of infection compared to SARS-CoV and MERS-CoV. Based on that, in this study, we employed the sequence to design antiviral peptides targeting the SARS-CoV-2 S protein RBD domain (S-RBD). Altogether, molecular docking, dynamic simulations and quantum biochemical analyses revealed that all peptides strongly bind to the RBD domain of SARS-CoV-2 S protein. Through this binding, the peptides can stop the correct cross talk between the cell and SARS-CoV-2, which is a critical step in the viral infection. Therefore, the inhibition or induction of incorrect interaction of the RBD domain and the human ACE2 receptor could be a potentially valuable strategy to combat COVID-19 caused by SARS-CoV-2.

2. Methodology

2.1. Design of peptides

The design of peptides followed the pipeline produced by Souza et al. (2020). The protein sequence chosen was angiotensin-converting enzyme 2 from Homo sapiens (ACE2), freely available in the NCBI database (https://www.ncbi.nlm.nih.gov/) under accession number Q9BYF1. The server used for the design was the AVPpred server (http://crdd.osdd.net/servers/avppred/) according to Thakur et al. (2012). First, the sequence of ACE2 was fractioned using AVPpred to produce peptides with chain lengths of 10, 15 and 20 amino acid residues. Then, all the peptides were run in AVPpred to find potential antiviral peptides. The AVPpred algorithm employs three criteria to select peptides: (1) alignment model; (2) composition model; and (3) physicochemical model. Based on those, the server classifies the sequences as AVP to potential antiviral peptides and non-AVP to non-potential antiviral peptides.

After the design, the best sequences selected by AVPpred were also run in the iAMPpred tool (http://cabgrid.res.in:8080/amppred/) (Meher et al., 2016) to calculate the probability of the sequences selected by AVPpred to be antiviral. The best sequences based on antiviral potential prediction were selected and characterized by physicochemical and biological properties using the iAMPpred tool.

The PEPFold server (https://bioserv.rpbs.univ-paris-diderot.fr/services/PEP-FOLD3/), a widely used computational tool to predict three-dimensional (3D) structures of linear peptides between 5 and 50 amino acids (Shen et al., 2014), was employed to build the 3D structure of ACE-2-derived peptides. The Pymol program was employed to evaluate the peptides’ 3D structures and their interaction with the ACE2 human protein.

2.2. Molecular docking (MD) assays

FRODOCK 3.12 (http://frodock.chaconlab.org/) (Ramírez-Aportela et al., 2016), one of the best servers for peptide–protein interaction, was used to perform all blind molecular docking assays. The peptides with the highest potential were chosen based on the docking score and repetition of poses in the output.

2.3. Molecular dynamic simulation

The complexes generated by the molecular docking tests were minimized and balanced to stabilize them before the
molecular dynamic assays. The force field of all OPLS-AA/L atoms (Moal & Bates, 2010; Robertson et al., 2015) was used to perform the topology, after which a 2-nm cubic box was created. Then, the SPC/E model of water was used for solvation of the box, the systems were neutralized, and the Na⁺ eCl⁻ ions were added at a concentration of 0.15 M. The minimization was performed until it reached negative potential energy and the lower maximum force of 1000 kJ mol⁻¹ nm⁻¹. The pressure and temperature balance was performed to 100 ps. Subsequently, molecular dynamic simulations were performed for 100 ns, and the resulting structures were used for the further analyses.

2.4. Interface analysis of the complexes formed between S-RBD and the studied peptides

The protein interactions calculator (PIC) server was used to analyze the interface interactions of the complexes. The PIC server (http://pic.mbu.iisc.ernet.in/) also determines the accessible surface area and distance of a residue from the protein’s surface based on analysis of a set of 3D structure coordinates. The PyMOL software, a molecular graphics tool widely used for three-dimensional visualization of molecules, was used to generate 3D figures and perform RMSD calculations. The Ligplot software (Laskowski & Swindells, 2011) was used to generate 2D figures with the respective representations of hydrophobic interactions and hydrogen bonds.

2.5. Quantum biochemistry calculation

This was performed according to a protocol established previously (Zhang & Zhang, 2003). Molecular fractionation with conjugate caps (MFCC) was carried out to calculate the full quantum mechanical interaction energies between two pairs of specific amino acid residues (Ri and Rj) involving the studied peptides and SARS-CoV-2 M pro, as follows, based on the work of Amaral et al. (2020):

\[
E(R_i - R_j) = E(C_{i-1}R_iC_{i+1} + C_{i-1}R_jC_{j+1}) - E(C_{i-1}R_iC_{i+1} + C_{i-1}C_iC_{i+1}) - E(C_{i-1}C_iC_{i+1} + C_{j-1}R_jC_{j+1}) + E(C_{i-1}C_iC_{i+1} + C_{j-1}C_jC_{j+1})
\]

where \(E(C_{i-1}R_iC_{i+1} + C_{i-1}R_jC_{j+1})\), the first term of the equation, is the total energy of the system formed by the residues Ri and Rj correctly capped; \(E(C_{i-1}R_iC_{i+1} + C_{i-1}C_iC_{i+1})\), the second term, is the total energy of the system formed by the capped residue Ri and the caps of the residue Rj; the third term, \(E(C_{i-1}C_iC_{i+1} + C_{j-1}R_jC_{j+1})\), represents the total energy of the system formed by the capped residue Rj and the caps of the residue Ri; and the last term, \(E(C_{i-1}C_iC_{i+1} + C_{j-1}C_jC_{j+1})\), accounts for the system’s total energy, formed by the caps of both residues Ri and Rj. The caps \(C_{j-1}C_{j+1}\) and \(C_{i-1}C_{i+1}\) are made from the residues covalently bound to the amine (carboxyl) groups of Ri and Rj. In the MFCC method used, all interaction between amino acid residues of the studied peptides and SARS-CoV-2 M pro separated from each other within an 8 Å range were calculated, considering a dielectric function approach of 40 (\(\epsilon = 40\)) for all interactions. The structural files (PDB format) obtained after molecular dynamic simulation and MFCC were used as inputs for density functional theory (DFT) calculations with DMOL³ (Delley, 2000).

3. Results

3.1. ACE2-derived peptide design

The AVPpred was set up to use the ACE2 sequence to produce peptides with 10, 15 and 20 amino acid residues. There were 100, 80 and 79 peptides generated, with 10, 15 and 20 amino acid residues, respectively, for a total of 259 peptides (Supplementary Tables S1–S3). Of those, AVPpred selected four peptides with antiviral potential, which were named ACE2-Dev-PepI, ACE2-Dev-PepII, ACE2-Dev-PepIII and ACE2-Dev-PepIV (Table 1).

As summarized in Table 1, all peptides were cationic, with positive charges ranging from +1 to +3, hydrophobic ratio from 45 to 60% and calculated molecular mass ranging from 1802.16 to 2587.14. Regarding biological properties, the iAMPpred tool revealed antiviral potentials of 80, 75, 63 and 35, respectively, for ACE2-Dev-PepI, ACE2-Dev-PepII, ACE2-Dev-PepIII and ACE2-Dev-PepIV (Table 2), corroborating the analysis of AVPpred. The in silico analyses revealed that all peptides had no hemolytic, allergenic or toxic potential (Table 2). This is interesting because designing peptides from the ACE2 human receptor can reduce any collateral effect.

In silico analyses also revealed that all peptides possibly interacted with DNA and RNA (Table 2). The interaction with RNA is particularly interesting because SARS-CoV-2 and other coronaviruses have RNA as genetic material. Looking forward to clinical application, we tested the resistance of these peptides in the intestinal-like environment. ACE2-Dev-PepII presented a half-life of 0.021 s, indicating low stability, which means that enzymes promptly digest it. ACE2-Dev-PepIV showed normal stability, as indicated by the half-life of 0.614 s. ACE2-Dev-PepII and ACE2-Dev-PepIII presented high stability, with half-life values of 3.461 and 1.669 s, respectively (Table 2). These values indicate the possibility of oral administration of the last two peptides.

The PEPFold server predicted that all ACE2-dev peptides contain long helices as secondary structures (Supplementary Figure S1). The Ramachandran plot (Table 1) revealed 98%, 99%, 95% and 99% of favorable regions for helix formation, respectively, for ACE2-Dev-PepI, ACE2-Dev-PepII, ACE2-Dev-PepIII and ACE2-Dev-PepIV (Table 1).

3.2. Molecular docking and dynamic simulations revealed interaction and stabilization between the ACE2-derived peptides and S-RBD

Given the large size of the entire SARS-CoV-2 S protein, many research groups have chosen to perform molecular docking and dynamic simulations using only the RBD structure (Amaral et al., 2020; Delley, 2000; Wu et al., 2020; Zhang & Zhang, 2003). Here, we followed the same approach. Molecular docking analyses showed that all ACE2-derived peptides interacted with S-RBD in the same region, with...
different scores, as revealed by the FRODDOCK server (Figure 1). The peptides ACE2-Dev-PepI, ACE2-Dev-PepII, ACE2-Dev-PepII, and ACE2-Dev-PepIV presented scores of 3003.43, 2909.40, 2829.25, and 3251.67 kJ.mol$^{-1}$, respectively.

Molecular dynamic simulation showed the stabilization of the complexes formed by ACE2-Dev-PepI, ACE2-Dev-PepII, ACE2-Dev-PepII, and ACE2-Dev-PepIV with S-RBD after assay of 30 ns, remaining stable up to 100 ns, with RMSD variations below 1 Å after 30 ns (Figure 2). The stable conformation obtained from each MD simulation was used to perform all further analyses.

### 3.3. Interaction between S-RBD and ACE2-Dev-PepI

The most relevant interactions among the amino acid residues from S-RBD and ACE2-Dev-PepI were by: Tyr$^{489}$, Tyr$^{473}$, Tyr$^{493}$, Phe$^{456}$, Ala$^{425}$, Tyr$^{489}$, Leu$^{455}$, Lys$^{458}$, Tyr$^{489}$, and Ala$^{425}$ of RBD with Phe$^{489}$, Trp$^{15}$, Trp$^{11}$, Trp$^{15}$, Phe$^{14}$, Trp$^{15}$, Trp$^{11}$, Trp$^{15}$, Met$^{10}$, and Trp$^{15}$ of ACE2-Dev-PepI. The interaction energies of interaction were, respectively, $-7.40, -7.22, -6.65, -5.54, -5.41, -4.57, -3.11, -2.90, -2.86$, and $-2.72$ kJ.mol$^{-1}$, with distances of 1.69, 1.76, 2.63, 2.54, 2.17, 2.40, 2.26, 4.70, 2.04 and 2.65 Å, respectively. All existing interactions up to a distance of 8 Å are reported in Supplementary Table S4.

The complex ACE2-Dev-PepI:S-RBD is supported by many interactions, such as hydrophobic and aromatic-aromatic interactions, along with hydrogen bonds (Figure 3(A,B,D)). The hydrophobic interactions were with residues Tyr$^{489}$, Leu$^{455}$, Tyr$^{473}$, Tyr$^{489}$, Phe$^{456}$, Phe$^{456}$, Tyr$^{489}$, and Phe$^{456}$ of S-RBD and residues Met$^{10}$ and Phe$^{14}$ of ACE2-Dev-PepI (Figure 3(A,B,D)). The aromatic–aromatic interactions were formed between residues Tyr$^{489}$ and Phe$^{456}$ of S-RBD and residues Trp$^{11}$ and Trp$^{15}$ of ACE2-Dev-PepI (Figure 3(A,D)).

Met$^{10}$, Trp$^{11}$, Phe$^{14}$ and Trp$^{15}$ were the most relevant amino acid residues of ACE2-Dev-PepI in the interaction with S-RBD, with respective interaction energies of $-6.78, -15.40, -17.24$ and $-23.81$ kJ.mol$^{-1}$ (Figure 3(C)).

### 3.4. Interaction of S-RBD with ACE2-Dev-PepI

Regarding the complex ACE2-Dev-PepI:S-RBD, interactions occurred between residues Arg$^{403}$, Glu$^{484}$, Leu$^{492}$, Tyr$^{473}$, Gln$^{493}$, Phe$^{456}$, Leu$^{455}$, Tyr$^{489}$, Leu$^{455}$ and Phe$^{490}$ of S-RBD, and residues Phe$^{15}$, Lys$^{9}$, Lys$^{9}$, Lys$^{9}$, Phe$^{5}$, Val$^{8}$, Phe$^{15}$, Leu$^{6}$, Lys$^{9}$ and Lys$^{9}$ of ACE2-Dev-PepI. The interaction energies of those interactions were, respectively, $-13.81, -11.00, -5.14, -4.98, -4.61, -4.34, -4.23, -3.91, -3.61, -3.21$ and $-2.93$ kJ.mol$^{-1}$ with distances of 1.63, 1.57, 2.18, 2.39, 2.85, 2.57, 2.39, 2.33, 2.31, 2.35 and 2.15 Å. The ACE2-Dev-PepI:S-RBD complex presented a repulsive interaction between Arg$^{403}$ of S-RBD and Leu$^{14}$ of ACE2-Dev-PepI, with interaction energy...
of +1.47 kcal.mol⁻¹ and distance of 5.09 Å. Supplementary Table S5 summarizes all interactions between ACE2-Dev-PepII and SARS-CoV-2 RBD up to a distance of 8 Å.

The interaction between ACE2-Dev-PepII and S-RBD occurred through hydrophobic, ionic, aromatic-aromatic, cation–π and hydrogen bonds (Figure 4(A–C)). Tyr₄⁸⁹, Phe₄⁵⁶, Phe₄⁵⁶, Tyr₄⁷₃, Ala₄⁷₅, Ala₄⁷₅, Tyr₄⁸⁹, Leu₄⁵⁵, Phe₄⁵⁶, Pro₄⁹¹, Tyr₄₅₃, Leu₄₅₅ and Tyr₅⁰⁵ of S-RBD had hydrophobic interactions with residues Met¹, Tyr⁴, Phe⁵, Phe⁵, Phe⁵, Leu⁶, Leu⁶, Val⁸, Val⁸, Met¹², Met¹², Phe¹⁵ of ACE2-Dev-PepII peptide (Figure 4(B,C)). Hydrogen bonds occurred between residues Phe⁴⁹⁰, Leu⁴⁹², Glu⁴⁸⁴ and Tyr⁴⁵₃ of S-RBD and residues Lys⁹, Lys⁹, Lys⁹ and Met¹² of ACE2-Dev-PepII (Figure 4(A–C)).

Ionic interaction occurred between the Glu⁴⁸⁴ residue of S-RBD and Lys⁹ residue of ACE2-Dev-PepII. Four cation–π interactions happened between residues Lys⁴₅₈, Arg⁴₀₃, Tyr⁴₈⁹ and Phe⁴⁹⁰ of S-RBD and residues Phe⁵, Phe¹⁵, Lys⁹ and Lys⁹ of ACE2-Dev-PepII (Figure 4(C)). Finally, the Phe⁴⁵₆, Phe⁴⁵₆, Tyr⁴₇₃ and Tyr⁵⁰⁵ residues of S-RBD had aromatic–aromatic interactions with the residues Tyr⁴, Phe⁵, Phe⁵ and Phe¹⁵ of ACE2-Dev-PepII (Figure 4(C)).

The most relevant amino acid residues of ACE2-Dev-PepII that interacted with S-RBD were Phe⁵, Leu⁶, Val⁸, Lys⁹, Met¹² and Phe¹⁵ with the interaction energies of −16.11, −12.78, −9.23, −31.58, −5.95 and −20.79 kcal.mol⁻¹, respectively (Figure 4(D)).

3.5. Interaction between S-RBD and ACE2-Dev-PepIII

In the complex formed between ACE2-Dev-PepIII::S-RBD, the main interactions were by residues Lys⁴¹₇, Arg⁴₀₈, Tyr⁴₅₃, Glu⁴⁰₆, Tyr⁴₈⁹, Leu⁴⁵₅, Gln⁴₉₃, Gln⁴₉₃, Gln⁴₉₃ and Phe⁴⁵₆ of S-
RBD with residues Glu\(^7\), Phe\(^2\), Arg\(^{10}\), Arg\(^{10}\), Phe\(^{14}\), Phe\(^{14}\), Trp\(^9\), Val\(^{13}\), Arg\(^{10}\) and Phe\(^{14}\) of ACE2-Dev-PepIII. The interaction energies were, respectively, \(-11.04\), \(-8.78\), \(-5.04\), \(-4.88\), \(-3.90\), \(-3.81\), \(-3.34\), \(-3.24\), \(-3.22\) and \(-3.04\) kcal.mol\(^{-1}\) and distances of 1.59, 2.53, 1.89, 4.01, 2.48, 2.23, 2.01, 2.66, 2.51, 2.62 Å, respectively. Repulsive interactions occurred between residues Glu\(^{406}\) and Arg\(^{403}\) of SARS-CoV-2 RBD and residues Glu\(^7\) and Arg\(^{10}\) of ACE2-Dev-PepIII, with interaction energies of \(+1.42\) and \(+1.98\) kcal.mol\(^{-1}\), respectively. All interactions between ACE2-Dev-PepIII and SARS-CoV-2 RBD up to a distance of 8 Å are reported in Supplementary Table S6.

ACE2-Dev-PepIII interacted with S-RBD through hydrophobic, ionic, aromatic-aromatic, cation–π interactions and hydrogen bonds. The residues Tyr\(^{449}\), Tyr\(^{498}\), Glu\(^{498}\), Gln\(^{498}\), Phe\(^{490}\), Tyr\(^{489}\), Tyr\(^{489}\), Phe\(^{456}\), Phe\(^{456}\) and Leu\(^{455}\) of S-RBD and residues Tyr\(^{449}\), Glu\(^{498}\), Gln\(^{498}\), Leu\(^{18}\), Trp\(^{11}\), Leu\(^{18}\), Asn\(^{17}\), Leu\(^{6}\), Pro\(^{3}\), Leu\(^{6}\) and Leu\(^{7}\) of ACE2-Dev-PepIV. The interaction energies were \(-5.27\), \(-5.07\), \(-4.99\), \(-4.14\), \(-4.05\), \(-3.91\), \(-3.85\), \(-3.82\), \(-3.40\), \(-3.04\) and \(-3.03\) kcal.mol\(^{-1}\), with distances of 2.22, 2.92, 2.18, 2.25, 2.25, 3.43, 1.71, 2.22, 2.51, 2.12 and 2.22 Å, respectively. The repulsive interaction was between the residue Gly\(^{485}\) of S-RBD and Leu\(^{7}\) of ACE2-Dev-PepIV, with the interaction energy of \(+0.54\) kcal.mol\(^{-1}\). All interactions between ACE2-Dev-PepIV and SARS-CoV-2 RBD up to a distance of 8 Å are reported in Supplementary Table S7.

### 3.6. Interaction between S-RBD and ACE2-Dev-PepIV

The main interactions between amino acid residues were driven by Tyr\(^{449}\), Tyr\(^{498}\), Glu\(^{498}\), Gln\(^{498}\), Phe\(^{456}\), Phe\(^{456}\), Phe\(^{456}\) and Leu\(^{455}\) of S-RBD and residues Leu\(^{18}\), Trp\(^{11}\), Leu\(^{18}\), Asn\(^{17}\), Leu\(^{6}\), Pro\(^{3}\), Leu\(^{6}\) and Leu\(^{7}\) of ACE2-Dev-PepIV. The interaction energies were \(-5.27\), \(-5.07\), \(-4.99\), \(-4.14\), \(-4.05\), \(-3.91\), \(-3.85\), \(-3.82\), \(-3.40\), \(-3.04\) and \(-3.03\) kcal.mol\(^{-1}\), with distances of 2.22, 2.92, 2.18, 2.25, 2.25, 3.43, 1.71, 2.22, 2.51, 2.12 and 2.22 Å, respectively. The repulsive interaction was between the residue Gly\(^{485}\) of S-RBD and Leu\(^{7}\) of ACE2-Dev-PepIV, with the interaction energy of \(+0.54\) kcal.mol\(^{-1}\). All interactions between ACE2-Dev-PepIV and SARS-CoV-2 RBD up to a distance of 8 Å are reported in Supplementary Table S7.
Hydrophobic, and aromatic–aromatic interactions along with hydrogen bonds are the interactions that stabilize the ACE2-Dev-PepIV::S-RBD complex. Hydrophobic interactions occurred between ACE2-Dev-PepIV and residues Phe456, Phe456, Ala475, Tyr489, Tyr489, Tyr421, Leu455, Phe456, Leu455, Phe456, Tyr473, Tyr489, Pro491, Leu455, Leu455, Phe490, Tyr453, Leu455 and Tyr449 of S-RBD (Figure 6B,D). Eight hydrogen bonds occurred between residues Phe490, Gln493, Gln493, Gln498, Gln498, Gln498, Gln498, and Gln498 of S-RBD and residues Trp11, Trp15, Phe14, Phe14, Asn17, Asn17, Tyr19 and Tyr19 of ACE2-Dev-PepIV, respectively (Figure 6A,B,D). Aromatic–aromatic interaction occurred between Phe490 of S-
RBD and Trp11 residue of ACE2-Dev-PepIV, respectively (Figure 6(A,D)). Pro3, Leu6, Leu7, Trp11, Phe14, Asn17 and Leu18 were the main amino acid residues of ACE2-Dev-PepIV that interacted with S-RBD, with interaction energies of $-8.55$, $-10.54$, $-19.27$, $-16.08$, $-10.03$, $-8.26$, $-14.77$ kcal.mol$^{-1}$ (Figure 6(C)).

3.7. Quantum biochemistry description

ACE2-Dev-PepI mainly interacted with residues Tyr489, Ala475, Tyr473, Phe456, Leu455, Asn487 and Lys458 of S-RBD, with interaction free energies of $-21.54$, $-8.78$, $-7.23$, $-6.27$, $-3.91$, $-3.17$ and $-2.90$ kcal.mol$^{-1}$, respectively (Figure 7(A)). The ACE2-Dev-PepII peptide interacted primarily with residues Arg403, Glu484, Gln493, Leu455, Phe456, Tyr489, Tyr473, Leu492, Pro491, Asn487, Tyr505, Ala475 and Phe490 of S-RBD, with interaction energies of $-12.67$, $-11.03$, $-10.64$, $-10.23$, $-9.92$, $-9.42$, $-7.04$, $-5.29$, $-4.87$, $-4.42$, $-4.07$, $-3.78$ and $-3.43$ kcal.mol$^{-1}$, respectively (Figure 7(B)). The ACE2-Dev-PepIII peptide mainly interacted with the amino acid residues Lys417, Gin493, Arg428, Leu455, Tyr453, Gin456, Tyr489, Gin490, Phe458, Tyr453 and Asp405 of the S-RBD, with interaction energies of $-12.13$, $-10.56$, $-9.40$, $-8.79$, $-6.08$, $-5.02$, $-4.85$, $-3.92$, $-3.55$, $-3.31$ and $-3.31$ kcal.mol$^{-1}$, respectively (Figure 7(C)). ACE2-Dev-PepIV mainly interacted with residues Leu455, Phe456, Gin493, Tyr489, Tyr449, Phe490, Ser494, Pro491, Tyr453, Ala475 and Gly496 of S-RBD, with interaction energies of $-14.65$, $-13.38$, $-11.44$, $-10.72$, $-10.58$, $-6.60$, $-6.22$, $-4.19$, $-4.07$, $-3.22$, $-3.14$ and $-3.12$ kcal.mol$^{-1}$, respectively (Figure 6(C)).

ACE2-Dev-PepII and ACE2-Dev-PepIV peptides had the lowest interaction energy, of $-112.8$ and $-113.9$ kcal.mol$^{-1}$, respectively, with S-RBD, so they have highest potentials to inhibit the interaction between S-RBD and ACE2 receptor. ACE2-Dev-PepI and ACE2-Dev-PepIII presented total interaction energies, $E(t)$, equal to $-64.9$ and $-84.6$ kcal.mol$^{-1}$, respectively (Figure 8). Energy convergence was observed in all complexes formed between ACE2-derived peptides and S-RBD after a distance greater than 6 Å, with minimal variations seen after that distance (Figure 8).

3.8. ACE2-derived peptides induced wrong interaction between S-RBD and the ACE2 receptor

All ACE2-derived peptides induced incorrect binding of S-RBD with the ACE2 receptor. The redocking confirmed the reliability of the docking tool, since the conformation generated by the redocking (Figure 9(B)) was similar to the crystal structure used as control (Figure 9(A)). When S-RBD was bound to ACE2-Dev-Pep, ACE2-Dev-PepI, ACE2-Dev-PepII or ACE2-Dev-PepIV peptides could not recognize the ACE2 receptor in the correct conformation (Figure 9(C–F)). The ACE2 region that generally interacts with S-RBD was no longer able to interact in the correct conformation with S-RBD.
4. Discussion

The development of vaccines is the most crucial measure to block SARS-CoV-2 spread and infection. Even though many research groups worldwide are rushing to develop an efficient vaccine against SARS-CoV-2, an undesirable problem has arisen. Some studies have shown the immunological memory mediated by IgGs anti-SARS-CoV-2 is brief, only around three months. Besides that, there are reports of patients infected twice by SARS-CoV-2 (Diamond & Pierson, 2020; Tay et al., 2020). This problem related to immunity...
offered by the vaccine to SARS-CoV-2 represents a considerable challenge to the world population. Therefore, research for new molecules is imperative to abolish or even attenuate its symptoms.

One approach to develop therapies quickly is repositioning of already available antiviral drugs to treat SARS-CoV-2 (Yan et al., 2020), which has not been successful so far. The most employed way to discover possible alternative compounds against SARS-CoV-2 is computational screening (Diamond & Pierson, 2020; Tay et al., 2020). By employing computational screening, it is possible to choose as target a vital protein to SARS-CoV-2 infection, such as RNA polymerase, a main protease and S protein (Elfiky, 2020; Souza et al., 2020). For instance, Elfiky (Zhang et al., 2020) used molecular docking to test many conventional antiviral drugs such as galidesivir, remdesivir and tenofovir against the RNA polymerase of SARS-CoV-2. In turn, Wu et al. (2020) performed molecular docking simulation of drugs such as antihypertensives, antifungals and anticoagulants against SARS-CoV-2 targets.

The spike glycoprotein of coronaviruses is an essential protein to infection. It has two portions, S1 outside the virus envelope, which is connected to S2, a transmembrane portion attached to the virus envelope. S1 possesses the RBD domain, which interacts with ACE2. After this interaction, the S2 portion is responsible for membrane fusion and virus entry (Hoffmann et al., 2020; Yuan et al., 2017). The S-RBD domain possesses high mutational rates, characterizing it as the most variable region of the coronavirus genome (Wu et al., 2020; Zhou et al., 2020).

In SARS-CoV-like viruses, there are six amino acid residues critical to the interaction between the RBD domain and the ACE2 receptor. The mutations accumulated by SARS-CoV-2 lead to five amino acid residues that are different from in to SARS-CoV. In SARS-CoV, the residues are Tyr455, Leu486, Asn494, Asp495, Thr501 and Tyr506. In contrast, in SARS-CoV-2,
the residues are Leu<sup>455</sup>, Phe<sup>486</sup>, Glu<sup>494</sup>, Ser<sup>495</sup>, Asn<sup>501</sup> and Tyr<sup>506</sup> (Andersen et al., 2020; Walls et al., 2020). These differences in the SARS-CoV-2 RBD domain allow it to bind to ACE2 with an affinity 20 times higher than SARS-CoV (Andersen et al., 2020). The ACE2 receptor is expressed in different human tissues, such as kidneys, gut, brain, liver, heart and lungs. By using it to enter the cells, SARS-CoV-2 can infect nearly all these tissues, causing SARS-CoV-2 viral sepsis, meaning the virus can infect several tissues at the same time (Li et al., 2020).

Given the importance of interaction between S-RBD and ACE2, several research groups have been seeking molecules that can block this interaction, either by interaction with S-RBD or with the ACE2 receptor, (Choudhary et al., 2020; de Oliveira et al., 2020; Wu et al., 2020). Choudhary et al. (2020) employed molecular dynamic simulations to find ligand molecules that interact with the ACE2 receptor and thus block interaction with SARS-CoV-2 RBD. This can be a two-way road, because by blocking the ACE2 receptor, SARS-CoV-2 cannot recognize it and does not establish infection. However, choosing to block the ACE2 receptor at the same time makes it unavailable to the cells, and hence produces several collateral effects. In a virtual screening, Wu et al. (2020) found a flavonoid from citrus fruit, called hesperidin, which interacted with RBD, blocking its interaction with ACE2. However, hesperidin has two highly undesired side effects: It induces bleeding disorders and low blood pressure. de Oliveira et al. (2020) tested azithromycin, hydroxychloroquine and chloroquine by molecular dynamics against SARS-CoV-2 RBD. These drugs do bind to RBD, but with low energy.

Here, we employed an in silico approach but with a different idea, focused on SARS-CoV-2 spike protein, specifically in the RBD domain. Instead of looking for molecules to interact with the ACE2 receptor, we used the sequence of the human ACE2 receptor to design synthetic peptides derived from it to target S-RBD. Out of 259 peptides (Supplementary Tables S1–S3), ACE2-dev-pepI, ACE2-dev-pepII, ACE2-dev-pepIII and ACE2-dev-pepIV deserved attention.

Molecular docking and dynamic simulations revealed that all ACE2-derived peptides interacted efficiently with S-RBD (Table 1, Figures 1–8). This is a pioneer study employing quantum biochemistry to analyze peptides’ interaction against SARS-CoV-2 RBD (Supplementary Tables S4–S7). Quantum biochemistry calculations (Morais et al., 2020) revealed the individual contribution of each amino acid residue of the ACE2-derived peptides and those of S-RBD. Therefore, these analyses showed that hydrogen bonds and ionic, aromatic, cation-pi and hydrophobic interactions are essential to attractive or repulsive interactions between the ACE2-derived peptides and S-RBD (Figures 3–7). As shown in Figure 8, the quantum biochemical calculations taking into consideration each amino acid energy level showed that the total interaction energy values between SARS-CoV-2 RBD and ACE2-dev-pepI, ACE2-dev-pepII, ACE2-dev-pepIII and ACE2-dev-pepIV were −64.9, −112.8, −84.6 and 1139 kcal.mol<sup>−1</sup>, respectively (Figure 8). Further based on the quantum calculations, ACE2-dev-pepIV was the peptides with the highest affinity to bind with S-RBD, followed by ACE2-dev-pepIII, ACE2-dev-pepII and ACE2-dev-pepI.

Since this is the first study to apply quantum biochemistry calculations to analyze the interactions of peptides with S-RBD, our results can only be compared with those reported by Campos et al. (2020), who also investigated the interaction of two peptides against the Zika virus protease. By quantum biochemistry, the authors showed that the interaction energies of the peptides cn-716 and acyl-KR-aldehyde with the protease NS2B–NS3 were −63.35 kcal.mol<sup>−1</sup> and −71.4 kcal.mol<sup>−1</sup>, respectively. Our peptides interacted with S-RBD even more strongly than did cn-716 and acyl-KR-aldehyde to the protease NS2B–NS3.

Moreover, the effectiveness of other non-peptide-like antiviral drugs against S-RBD has been assayed. For example, de Oliveira et al. (2020) tested by molecular docking the interaction of the drugs azithromycin, hydroxychloroquine and chloroquine, which are used to treat bacterial infection and malaria, respectively, and study is about drug repositioning or repurposing, employed to speed up the drug discovery process by identifying a novel clinical use for an existing drug approved for a different indication (Yan et al., 2020). Our results revealed that ACE-derived peptides strongly bind to S-RBD. However, two questions remain; what are the consequences of that interaction? Can these peptides block or induce a wrong interaction between S-RBD and ACE2? The results presented here guide us to answer yes. As presented in Figure 9, the crystal structure (Figure 9(A)), the redocking of those structures (Figure 9(B)), and all ACE2-derived peptides when complexed with S-RBD did not block interaction between S-RBD and the ACE2 receptor, instead inducing an incorrect interaction between them (Figure (C–F)). These results strongly suggest that ACE2-derived peptides are efficient to prevent SARS-CoV-2 entry in cells, greatly reducing SARS-CoV-2 replication and avoiding COVID-19 establishment.

As expected, the ACE2-derived peptides presented high affinity to bind with S-RBD, and the results suggest these
peptides are efficient to block SARS-CoV-2 infection. Additionally, for being designed from a human protein, these peptides will likely cause no serious collateral effects, unlike other drugs. The in silico analyses revealed these peptides have no toxic, allergenic or hemolytic potential against humans. Additionally, stability tests suggested high stability of ACE2-Dev-pepl, ACE2-DevPeplII and ACE2-Dev-PepIV in the intestinal environment indicating possible oral administration.

5. Conclusion
Quantum biochemistry and molecular dynamic simulations revealed that the ACE2-derived peptides interact physically with S-RBD, blocking its interaction with the ACE2 receptor and thus virus entry in the cell. These findings suggest that ACE2-derived peptides are small antiviral molecules that can potentially prevent cell invasion by SARS-CoV-2 and thus its
replication in vivo. However, further investigation is required to prove this hypothesis. In conclusion, this pioneering in silico investigation opens an opportunity for further in vivo investigations of these peptides, aiming to discover new drugs and entirely new perspectives to treat COVID-19. For instance, peptide-based therapeutics have various advantages compared to traditional small-molecule drugs, such as higher specificity to selected targets, low toxicity because accumulation in the body is improbable, and less complex, costly and time-consuming synthesis (Yan et al., 2020).
