SUMMARY
Recent studies suggest that the sterol metabolic network participates in the interferon (IFN) antiviral response. However, the molecular mechanisms linking IFN with the sterol network and the identity of sterol mediators remain unknown. Here we report a cellular antiviral role for macrophage production of 25-hydroxycholesterol (cholest-5-en-3β,25-diol, 25HC) as a component of the sterol metabolic network linked to the IFN response via Stat1. By utilizing quantitative metabolome profiling of all naturally occurring oxysterols upon infection or IFN-stimulation, we reveal 25HC as the only macrophage-synthesized and -secreted oxysterol. We show that 25HC can act at multiple levels as a potent paracrine inhibitor of viral infection for a broad range of viruses. We also demonstrate, using transcriptional regulatory-network analyses, genetic interventions and chromatin immunoprecipitation experiments that Stat1 directly coupled Ch25h regulation to IFN in macrophages. Our studies describe a physiological role for 25HC as a sterol-lipid effector of an innate immune pathway.

INTRODUCTION
Metabolism and innate immunity are increasingly viewed as being connected and pathway mechanisms exist for sharing resources and cross-regulation (Im et al., 2011).

Cholesterol is a vital component of cellular membranes and is critical to a broad range of cellular functions. As a result, elaborate homeostatic mechanisms have evolved to control sterol metabolism at multiple levels within and outside the cell (Horton et al., 2002). Importantly, several of these mechanisms involve 25-hydroxycholesterol (25HC). The synthesis of transcripts encoding virtually all enzymes of the sterol biosynthesis pathway is regulated by the transcription factor Srebp2. Moreover, the Srebp2 processing pathway, responsible for endoplasmic reticulum retention of the protein or proteolytic activation and translocation to the nucleus, is subject to inhibition by 25HC (Gong et al., 2006; Radhakrishnan et al., 2007; Yabe et al., 2002). In the mevalonate arm of the pathway, HMGR serves as a key control point (Rodwell et al., 1976) and is further regulated by oxysterols (in particular 25HC) through posttranslational degradation elicited by INSIG1. In addition, 25HC may also regulate cholesterol homeostasis through its ability to activate liver X receptors (LXR) and a variety of other isoprenoid and sterol metabolic intermediates can negatively feedback on sterol biosynthesis (Espenshade and Hughes, 2007; Song et al., 2005).

Viruses are known to alter cellular lipid metabolism to facilitate their own multiplication and, importantly, inhibition of cholesterol and fatty acid biosynthetic pathways has been shown to curtail virus replication, maturation and secretion (Clark et al., 2012; del Real et al., 2004; Munger et al., 2008; Peña and Harris, 2012; Potena et al., 2004; Spencer et al., 2011; Taylor et al., 2011; Ye et al., 2003; Yu et al., 2012). In this regard, interferon (IFN)-mediated downregulation of the sterol biosynthesis pathway has been shown to be an integral part of M0 host defense (Blanc et al., 2011; Wattersn et al., 2012). It is well recognized that IFNs, in particular type I, play a pivotal role in inhibiting viral growth through the activation of IFN-stimulated genes (ISGs). However, the specific functions of many ISGs and the mechanisms by which they restrict viral replication are not well defined (O’Neill and Bowie, 2010). The notion that there is an intrinsic connection between the sterol network and IFN is further supported by studies showing IFN modulation of the cholesterol
Coupling 25HC to IFN Antiviral Response via Stat1

RESULTS

Quantitative Oxysterol Profiling of Infected or Interferon-Activated Primary Macrophages

We speculated that the synthesis of oxysterols might have a role in the negative regulation of sterol biosynthesis upon infection (Blanc et al., 2011). Accordingly, we performed a comprehensive quantitative determination of all known naturally occurring side-chain and steroid-ring oxysterol metabolites that are produced and/or secreted by either infected or interferon (IFN-β or IFN-γ) stimulated primary MΦ during infection and upon IFN stimulation. We provide evidence for a biological role for 25HC as a lipid effector of the innate immune response, highlighting the targeting of host metabolic regulatory networks during viral infections and, more broadly, inflammation.

The results of this oxysterol-metabolome and secretome screen are summarized in Figure 1C (intracellular) and 1D (secreted). Interestingly, in this study noticeable amounts of 25HC were found in unstimulated MΦ but not media—a result that perhaps reflects a pre-existing subprimed activation of MΦ (Kropp et al., 2011). Strikingly, amounts of only 25HC were markedly increased by infection or treatment with MCMV or IFN (β or γ), respectively (Figures 1C and 1D). In this study, the only other detectable oxysterols (with systemic names provided in brackets) were 24(S),25-epoxycholesterol (24S,25-epoxycholest-5-en-22-one), cholest-5-ene-3β,6α-diol, cholest-4-ene-3β,6α,25-triol, cholest-5-ene-3β,19-diol, cholest-5-ene-3β,22S-diol, cholest-5-ene-3β,24R-diol, cholest-5-ene-3β,7β,25-triol, cholest-(25R)-5-en-27-oic acid, and 3β-hydroxycholesterol-23S-5-en-26-oic acid.

The results of this oxysterol-metabolome and secretome screen are summarized in Figure 1C (intracellular) and 1D (secreted). Interestingly, in this study noticeable amounts of 25HC were found in unstimulated MΦ but not media—a result that perhaps reflects a pre-existing subprimed activation of MΦ (Kropp et al., 2011). Strikingly, amounts of only 25HC were markedly increased by infection or treatment with MCMV or IFN (β or γ), respectively (Figures 1C and 1D). In this study, the only other detectable oxysterols (with systemic names provided in brackets) were 24(S),25-epoxycholesterol (24S,25-epoxycholest-5-en-22-one), cholest-5-ene-3β,6α-diol, cholest-4-ene-3β,6α,25-triol, cholest-5-ene-3β,19-diol, cholest-5-ene-3β,22S-diol, cholest-5-ene-3β,24R-diol, cholest-5-ene-3β,7β,25-triol, cholest-(25R)-5-en-27-oic acid, and 3β-hydroxycholesterol-23S-5-en-26-oic acid.

The results of this oxysterol-metabolome and secretome screen are summarized in Figure 1C (intracellular) and 1D (secreted). Interestingly, in this study noticeable amounts of 25HC were found in unstimulated MΦ but not media—a result that perhaps reflects a pre-existing subprimed activation of MΦ (Kropp et al., 2011). Strikingly, amounts of only 25HC were markedly increased by infection or treatment with MCMV or IFN (β or γ), respectively (Figures 1C and 1D). In this study, the only other detectable oxysterols (with systemic names provided in brackets) were 24(S),25-epoxycholesterol (24S,25-epoxycholest-5-en-22-one), cholest-5-ene-3β,6α-diol, cholest-4-ene-3β,6α,25-triol, cholest-5-ene-3β,19-diol, cholest-5-ene-3β,22S-diol, cholest-5-ene-3β,24R-diol, cholest-5-ene-3β,7β,25-triol, cholest-(25R)-5-en-27-oic acid, and 3β-hydroxycholesterol-23S-5-en-26-oic acid.
revealed that the majority of 25HC was secreted during the first 8 hr of incubation, and levels continued to rise more gradually until the 24 hr endpoint (Figures 2A and 2B). As previously reported for cells grown in normal media, a steady and significant fall in free cholesterol, and its direct precursor desmosterol, was observed with time suggesting a reduced biosynthetic output (Figure 2C; data not shown) (Watterson et al., 2012). In summary, the LC-MS(MS n) experiments revealed 25HC as the only oxy-sterol notably upregulated following macrophage infection or activation by IFNs. This occurred during the first hours after infection or treatment before overall levels of cholesterol in treated cells fell notably below those of the control. Figures 2D and 2E show data that suggests that the highly-specific increase in 25HC was attributable to upregulated expression of the hydroxylase Ch25h; levels of the only other expressed hydroxylases Cyp27a and Cyp7a that are also implicated in 25HC metabolism were unaltered. When a different perspective on this result was sought and interferon or polyI:C was used to stimulate BMDMs, increased levels of secreted 25HC were clearly detectable 4 hr after treatment. PolyI:C is a potent Tlr3 agonist that stimulates high levels of Ifn-β production (Figure 2F). Notably, in contrast to the observed decline in Ch25h transcript expression, levels of secreted 25HC metabolite levels remained relatively high until 24 hr in these experiments. We conclude from the above data that interferon activation or MCMV infection of Mφ results in a large and highly focused production of intracellular and secreted 25HC.

**Exogenous Treatment and Endogenous Secretion of 25HC by BMDM Has Broad Antiviral Potency**

It is possible that 25HC might function as an antiviral mediator in the IFN-regulated sterol metabolic network (Blanc et al., 2011). To test this idea, we sought to address whether physiologically relevant concentrations of 25HC, secreted by activated Mφ, are capable of conferring an antiviral state. We first determined in dose-response experiments the inhibitory concentrations (IC) for viral growth of MCMV in normal serum (i.e., sterol-replete media would favor restricted Srebp2 processing). Figure 3A shows that under these conditions 25HC has an IC10 of approximately 0.1 μM and an IC50 of 2 μM and did not induce a cytotoxic effect (see Figure S1 available online). Because this level of inhibition is greater than...
the known levels of 25HC that are sufficient to disrupt Srebp processing (Radhakrishnan et al., 2007), we infer from these experiments that in sterol-replete conditions 25HC is unlikely to involve the Srebp processing pathway for maximal antiviral activity (Adams et al., 2004; Yabe et al., 2002).

Because cells grown under lipid-deficient media conditions have an increased dependency on sterol biosynthesis, we also evaluated the antiviral effect of 25HC under lipid-depleted conditions (Sun et al., 2007). As shown in Figures 3A and 3B, there is an increase in sensitivity of MCMV to inhibition by 25HC under
these conditions. This antiviral effect is specific to 25HC because other related enzymatically generated oxysterols, 19-HC and 7α-HC, fail to repress viral infection (Figure 3B). These oxysterols are known not to inhibit the Srebp-pathway (Radhakrishnan et al., 2007). In contrast, other oxysterols known to inhibit the Srebp-pathway through INSIG, such as 27-HC and 24(S), 25 epoxycolesterol, are similarly capable of inhibiting MCMV growth (Figure S1B). These observations point to the possibility that although the Srebp pathway is not absolutely essential for mediating the antiviral effects of 25HC, it might contribute toward enhancing the sensitivity to 25HC inhibition. The physiological relevance for the lipid dependency is presently unclear. The differential sensitivities under sterol-replete and -depleted conditions raise the possibility for multiple levels of control. To determine whether the differential modes of inhibition by 25HC are specific to MCMV or whether it might have a broader antiviral role, we next evaluated, in normal or lipid-depleted conditions, its potency to inhibit a range of other viruses in different cell systems. Figures 3C–3F show the quantitative determination of the dose-dependent potency of 25HC to inhibit Influenza A (H1N1), herpes simplex virus-1 (HSV-1), varicellar zoster virus (VZV) and murine gamma herpes virus 68 (MHV-68) viral infections in MDCK, HeLa, MeWo, and BHK cells, respectively. The results of these titration experiments clearly show a broad and highly potent (IC50 values ranging from 20 nM to 750 nM) antiviral role of 25HC (Figures 3D–3F). This effect is selective because Figure S1C shows that under the conditions tested, 25HC does not specifically inhibit Adenovirus 5 or 19a. We conclude that 25HC has a high potency to inhibit a broad spectrum of viruses from high to low physiological concentrations depending on lipid conditions and virus-host cell system.

The pharmacologic agent LY295427 (3z,4z,5a)-4-(2-prope- nylchostan-3-ol) is a known antagonist of 25HC, whereas LY306039, the 3β-isomer of LY295427, fails to derepress the effect of 25HC (Janowski et al., 2001). We used these agents to test whether they have any efficacy in interfering with the antiviral activity mediated by 25HC. Figure 4A shows the ability of exogenous 25HC to potently inhibit viral growth and that the observed antiviral effect can be completely blocked in the presence of LY295427 but not LY306039. These results validated our subsequent use of LY295427 in interfering with endogenously secreted 25HC. Accordingly, conditioned media (10 hr post-treatment) from mock-treated, infected, Ifn-β, or Ifnγ-treated Mφ was incubated with vehicle alone, or with LY295427 or LY306039 and then applied to MCMV-infected NIH 3T3 cells. As expected, mock-conditioned media failed to inhibit viral growth and drug treatment had no effect (Figure 4B). Meanwhile, conditioned media from infected or IFN-treated cells had pronounced antiviral activity. In the presence of LY295427, antiviral activity was partially blocked (Figure 4B). We interpret the results of these experiments to show that endogenously secreted 25HC has a potent antiviral activity and, if we assume, LY295427 is an exclusive inhibitor of 25HC, this accounts for at least 40%–50% of the antiviral secretome activity. It is likely that the secretion of other antiviral cytokines rather than an incomplete blockade provides the remaining antiviral activity. Overall, these experiments demonstrate that Mφ activated Ch25h generates biological antiviral activity through paracrine, and in the case of Mφ also autocrine effects of 25HC.

25HC Antiviral Actions Are LXR Independent and Enantioselective

The above studies raise the possibility for potentially direct and indirect modes of 25HC action. It is conceivable that inhibitory effects of 25HC above 0.5 μM might involve an indirect membrane-mediated mechanism, whereas those below 0.5 μM may have a direct protein mediated mode of action. It is also plausible that 25HC could be metabolized to a more potent antiviral metabolite. A candidate pathway is the Epstein-Barr virus-induced gene 2 (EBI2/GPR183) enzyme system (Hannedouche et al., 2011; Liu et al., 2011). The natural ligand for EBI2 has been identified as 7α,25-diHC. In this pathway, a critical enzyme required for the generation of 7α,25-diHC is CH25H, however, in our mouse experiments Ebi2 gene expression is downregulated in Mφ upon productive and nonproductive infection as well as polycltreatment, in an IFN-dependent manner (Figure 4C), suggesting that it is unlikely to be involved in the antiviral response. Intriguingly, the coordinated IFN suppression of the Ebi2 mediated 25HC-catabolic-pathway further underscores the highly focused 25HC Mφ response and is unlikely to involve an interme- diary metabolite mode of action.

To evaluate generalized membrane effects and further test the specificity of 25HC actions, we studied the activity of ent-25HC, an enantiomer of 25HC. In these experiments, we assumed the well-known ability of 25HC to interact and change the properties of cellular membranes would be enantiomer insensitive while protein specific inhibitory effects on viral growth would be restricted to 25HC. Figure 4D shows that ent-25HC has antiviral activity but only at concentrations exceeding 1 μM, which is below the nonselective effects of oxysterols on viral infection and is an order of magnitude less potent at inhibiting MCMV than 25HC (Figure 4D). These results show that the effect of 25HC on antiviral activity is highly enantio-selective, consistent with the idea that 25HC antiviral functions occurs through a specific protein target(s). Because ent-25HC can exert an antiviral effect at high concentrations it is likely that this activity occurs via an indirect mode of action mediated at the membrane level. Notably, the antiviral effect of ent-25HC provides evidence for Srebp-independent antiviral pathway that might act as a cofactor for membrane proteins or acting as a determinant for membrane lipid composition or compartmentalization (Contreras et al., 2012).

In the case of lipid-depleted conditions, our data is consistent with a subordinate inhibition of the Srebp pathway by 25HC and by other oxysterols such as 24S, 25-epoxycolesterol or 27-HC. Notably, these oxysterols are also known to activate LXR (Janowski et al., 2001). Thus, we next evaluated the transcriptional responses of LXR and Srebp target genes in Ifnγ-treated or MCMV-infected Mφ. In these experiments, molecular profiling of Ifnγ and MCMV infected Mφ every 30 min for 12 hr showed the expected downregulation of Srebp2 target messenger RNAs (mRNAs) including Insig1 (Figure 4E). However, the temporal dynamic changes were complex. In this analysis, increased expression of Ch25h mRNA levels is associated with a subsequent activation of the LXR target genes Myl1p and Abcg1. To directly test whether LXR ligand activation is sufficient to develop an antiviral state, we treated MCMV infected cells with 1 μM of the potent synthetic LXR ligands (G3965S and T0901317). Although these ligands were active in LXR-dependent reporter assays
Figure 4. Investigation of Specificity and Selectivity of 25HC Antiviral Activity, See Also Figure S2

(A) NIH 3T3 cells were infected with MCMV-GFP virus (MOI = 0.05) treated with 25HC in the presence or absence of Ly295427 (20 μM) or Ly306039 (20 μM). The level of infection was measured by determining the GFP fluorescence level after 72 hr infection. n = 3, data are mean ± SEM (three replicates per experiment).

(B) NIH 3T3 cells infected with MCMV-GFP virus (MOI = 0.05) received conditioned medium from BMDM infected, or treated with IFN-β (25 U/ml) or IFN-γ (10 U/ml) ± 20 μM Ly295427 or 20 μM Ly306039. n = 3, and data are mean ± SEM (with three biological replicates per experiment).

(C) Expression analysis of Gpr183 (relative to t = 0) in WT, Ifnb−/− or Ifnar1−/− BMDM infected with MCMV or MCMVdie3 (MOI = 1) or treated with PolyI/C (10 ng/ml). Each column represents one time point and row represents one gene. Gene expression is shown as a pseudocolor – blue = decrease, yellow = increase. Log fold change values were calculated by subtracting the t = 0 signal value from the signal value at time points after infection or treatment.

(D) MEF were pretreated with 25HC or ent-25HC in delipidized medium for 24 hr and infected with MCMV-GFP (MOI = 1). n = 2, data are mean ± SEM (with three biological replicates per experiment).

(E) BMDM treated with 10 U/ml Ifn-γ or mock-treated (F). Heatmap showing temporal alterations in abundance of sterol-related transcripts in Ifn-γ-treated BMDM (E, relative to t = 0) or MCMV infected BMDM (F, relative to t = 0) as in (C).

(G) NIH 3T3 cells were pretreated with GW3965 (1 μM), T0901317 (1 μM) or 25HC (10 μM) in normal or delipidized medium for 24 hr and then infected with MCMV-GFP. After infection, all wells received fresh medium containing normal or delipidized serum and GW3975, T0901317, or 25HC. Data are normalized to negative controls treated with vehicle alone and are the mean of six independent experiments ± SEM (three biological replicates per experiment).

(H) MEFs were pretreated with GW3965 (1 μM), T0901317 (1 μM) or 25HC (10 μM) in normal or delipidized medium for 24 hr and then infected with MCMV-GFP as described in (G). Data are normalized to negative controls treated with vehicle alone and are the mean of six independent experiments ± SEM (three replicates per experiment).

(I) Left shows MEFs infected with MCMV (MOI = 0.1) incubated with 25HC (1 μM) and/or GGOH (20 μM) or MEV (20 μM) and MCMV titer determined by plaque assay. Data are mean of three independent experiments ± SEM. *p ≤ 0.05. Right shows that MEFs infected with MCMV (MOI = 0.1) were incubated with vehicle, 25HC (1 μM), and/or Farnesol (FOH – 20 μM) or Squalene (Sqle – 20 μM) and MCMV titer was determined by plaque assay. Data are the mean of two independent experiments.

(J) RISC-Free, Fnta, Fntb, Pggt1b, Rabggtb, Rabggta, or MCMV M54 siRNA (25nM) were reverse-transfected into NIH/3T3 cells. Forty-eight hr after transfection, cells were infected with MCMV-GFP (MOI = 0.05) and virus replication monitored. Data are normalized to RISC-free wells and are mean of six independent experiments ± SEM.*p < 0.05, **p < 0.01, *** < 0.001.

(K) Left shows that MEF were pretreated with 25HC (5 μM) or psoromic acid (20 μM) for 24 hr, infected with MCMV-GFP (MOI = 0.05), and then incubated with EMEM with the same concentrations of 25HC or psoromic acid. Data are normalized to vehicle treated wells and are mean of six independent experiments ± SEM. (error bars represent range).

25HC Antiviral Action Partially Involves the Mevalonate Branch, Blocking Postentry Viral Growth

A decrease in the Srebp2 target genes of the sterol pathway and especially the mevalonate–isoprenoid side branch is notable (in particular Mvd and Fdps) (Figures 4E and 4F). Mevalonate is a shared precursor of coenzyme Q, ubiquinone, dolichol, farnesyland geranylgeranyl pyrophosphates. The latter two isoprenoids are necessary for protein prenylation. Many viruses require prenylation of essential viral or host proteins (e.g., the large delta antigen of HDV or the pseudorabies virus tegument protein) (Bordier et al., 2003; Clase et al., 2003) or (e.g., host protein FBL2 for hepatitis C virus [HCV] or RhoA activation for RSV) (Ye et al., 2003) (Wang et al., 2005) (Gower and Graham, 2001). In the case of MCMV, we find, upon inhibition of the prenyltransferase branch by RNAi, that viral replication is selectively reduced upon knockdown of GTTase II but not GTTase I or farnesyltransferase (Figure 4J), confirming previous work defining the dependency of MCMV for the isoprenoid pathway (Blanc et al., 2011). In the present study, Rabggtb and Rabggta small interfering RNA (siRNA) reduced the abundance of their target transcript by around 60% (Figure S4F) and none of the above siRNA significantly reduced cell viability (Figure S4D).

To investigate whether 25HC antiviral functions involve the mevalonate branch, we treated MCMV infected cells with nonsaturating inhibitory levels of 25HC (<1 μM) and coinubcated with mevalonalactone (MEV), geranylgeraniol (GGOH), or Farnesol (FOH), and the amount of infectious virus determined. In these metabolic rescue experiments, viral growth was restored with MEV or GGOH but not FOH (Figure 4I). However, in the presence of saturating inhibitory concentrations of 25HC (>5 μM), viral growth is not recovered with MEV, GGOH, or FOH cotreatment (data not shown) indicating that under these conditions the isoprenoid-prenylation arm is not required. It is possible that other derivatives such as dolichol may be required. Altogether, these investigations are indicative that for MCMV, 25HC blocking of the mevalonate branch imparts a contributory role but is not absolutely essential. As expected, inhibitors of GTTase I (GGTT-2133) or farnesyltransferases (FTI-277) fail to inhibit MCMV, whereas psoromic acid (an inhibitor of GTTase II [Deraeve et al., 2012]) restricts viral growth (Figure 4K). None of these compounds significantly affected cell viability (Figure S2E).

We next investigated at what stage in infection 25HC blocks MCMV growth. The results shown in Figure 5A indicate that the level of internalized MCMV genomes is unaffected by 25HC. Furthermore, in plaque reduction assays the number of primary infectious foci is equivalent in the presence or absence of 25HC (Figure 5E). These results argue against viral entry as a primary mode for MCMV inhibition. In this connection, we also find that 25HC is highly effective at blocking (at 40 nM inhibitory concentration) VZV infection of MeWo cells (Figure 3E). This represents an infection model in which cell-free virus is not produced and the infection process is exclusively dependent on cell-cell spread. 25HC at high concentrations has been shown to promote apoptosis, a well-characterized antiviral mechanism, in a range of cell types including MEFs (Rusiño1 et al., 2004). Notably, however, as shown for NIH 3T3 cells (Figure 5B), 25HC at high antiviral concentrations (10 μM) fails to significantly induce cellular apoptosis in comparison with staurosporine. Again, we cannot rule out that other cell-virus systems may

Immunity
Coupling 25HC to IFN Antiviral Response via Stat1

(Figure S2A), they failed to elicit an antiviral response and, therefore, we conclude that LXR activation is insufficient to affect viral inhibition of MCMV in both normal or lipid depleted media conditions (Figures 4G and 4H; Figures S2B and S2C).

(Figure 4G) n = 6 ± SEM. Right shows that RAW264.7 cells were pretreated for 24 hr with IFN-γ (10 U/ml) or 25HC (5 μM) for 4 hr, infected with GLucMCMV and at 2 or 4 hpi and Gaussia luciferase activity measured using supernatants. n = 6 ± SEM. Right shows that RAW264.7 cells were pretreated for 24 hr with IFN-γ (10 U/ml) or 25HC (2 μM), infected with MCMV (MOI = 2), in normal medium containing vehicle, IFN-γ (10 U/ml) or 25HC (2 μM) for 24 hr, relative abundance of the MCMV clef1 assayed by qRT-PCR. n = 3; mean ± SEM. *p ≤ 0.05.
employ a 25HC mediated apoptotic antiviral response. In this regard, we have found BMDM to be especially sensitive to 25HC concentrations above 2 μM.

We noted marked inhibitory effects on plaque development for all viruses investigated (Figure 5C–5G). Dose response analyses of MCMV plaque formation clearly indicated that the ability of the virus to spread decreased with increasing dose of 25HC (Figures 5C and 5D), while no statistical differences in numbers of infection foci in the presence or absence of 25HC were obtained (Figure S5E). In plaque reduction assays a significant dose-dependent difference in the diameter of the viral plaque was observed (Figure S5E). Similar results were also obtained from plaque reduction assays for influenza virus (Figure 5F). A simple mathematical model that best fits the experimental data is the one in which growth dominates over susceptibility to infection (Figure 5H; Figure S3F; Movie S1). In agreement, single hit growth analyses of MCMV and influenza infection show that 25HC effectively inhibits viral growth (Figure 5G) and for MCMV, 25HC inhibits yields of intracellular and secreted virus to the same extent (Figure 5G). However, in the case of HSV-1 we observed a significant difference in both plaque size and number of plaques (Figure 5F; Figure S3E) suggesting viral entry and growth can be affected and further indicating the multiple levels of control exerted by 25HC depending on the virus-host cell system.

In accordance with the above results we observed a reduction at the level of viral DNA replication by 25HC (Figure 5I). This is associated with reduced amounts of early (E1) and late (M115) gene expression in a 25HC dose-dependent manner strongly supporting a postentry stage inhibition of MCMV infection (Figure S3A). For MCMV Mφ infection, IFNs mediate antiviral effects through inhibition of the major immediate-early promoter (MIEP) (Kropp et al., 2011). We also find that 25HC imparts, in a dose dependent manner, inhibition of the MIEP monitored by using either reporter virus assay or the endogenous ie1 expression levels, resulting in approximately 50% inhibitory activity in comparison with IFNγ treatment (Figure 5J; Figures S3B and S3C).

Interferon Stimulation of 25HC Production Involves Direct Binding of Stat1 to Ch25h Promoter

A central question regarding the role of 25HC in terms of innate immunity is how IFN signaling precisely regulates Ch25h. Thus, in our next experiments we sought to investigate in further detail the regulatory interferon dependence of the 25HC responses by using host and viral genetic knockouts in our macrophage-infection experiments. First we assessed whether the IFN-β plays a role in mediating the induction 25HC in infection. Figure 6A shows that greater than 80% of the induction response of Ch25h is lost in Ifnb1−/− Mφ, whereas 100% of the response is eliminated in Ifnar1−/− Mφ. Because all type I IFNs signal through the Ifnar1 receptor, these results indicate that upon infection of Mφ, Ifn-β is the primary mediator, whereas other members of the type 1 interferon family serve a minor nonredundant role.

To determine whether a productive infection is required, we used a mutant virus (MCMVΔie3) that is fully proficient in infecting cells but fails to initiate viral gene expression. In the following experiments, infection of Mφ with MCMVΔie3 resulted in an equal response of Ch25h activation in comparison with the parental wild-type (WT) virus but with slightly delayed temporal kinetics (Figure 6B). In this case, and in comparison with Ifnar1−/−-infected cells, Ifn-β dominates the response (Figure 6B). These results show that productive infection is not required; indicating that pattern recognition receptor activation by the viral particle is sufficient to activate the transcriptional induction of Ch25h.

In our Mφ cultures, Ifn-γ is not expressed but, as shown in Figure 1, is a potent inducer of Ch25h activity. Figure 6C shows that infection or treatment with exogenous Ifn-β of Ifnar1−/− Mφ abolishes the induced levels of 25HC, whereas exogenous Ifn-γ treatment does not. Because signal transducer and activator of transcription factor 1 (Stat1) is activated by Ifn-γ though its receptor Ifngr and Stat1 and Stat2 are activated by Ifn-β through its receptor Ifnar1, we next tested the ability of MCMV, Ifn-β and Ifn-γ to activate Ch25h mRNA levels in Stat1−/− cells. Figure 6D clearly shows that genetic elimination of Stat1 results in the marked loss of the ability of Mφ to activate Ch25h upon infection or treatment with type 1 or type 2 IFNs.

To further investigate the kinetic transcriptional induction of Ch25h, we quantitatively determined the de novo synthesis of mRNA using 4-thiouridine incorporation. A schematic of this procedure is shown in Figure S4A. In these experiments, between 60 and 90 min after treatment, de novo synthesis of the Ch25h transcript increased by approximately 30-fold in Ifn-γ treated cells relative to the mock sample (Figure 6E). To test whether signaling from Ifnar1 was necessary for the induction of Ch25h during viral infection, we next conducted de novo synthesis experiments in Tyk2−/− macrophage cells. The results shown in Figure 6F indicate that direct signaling by the receptor rather than an indirect or secondary mode of activation is crucial in virus-induced Ch25h synthesis and is consistent with the possibility of Stat1 involvement in this process. To explore this possibility further, we next conducted a microarray analysis of de novo transcription during the first 8 hr after IFN-γ stimulation of macrophages. An unbiased clustering analysis of temporal differential synthesis profiles identified a subset of 51 gene transcripts kinetically related to Ch25h, including Ifr1 and Tap1, (Table S1; Figure 6G). Having demonstrated a notable increase in Ch25h transcript synthesis during the first 30 min after IFN-γ treatment, we sought to bioinformatically investigate promoter regions for common transcription factor binding sites. To this end, we applied a statistical analysis of transcription factor overrepresentation in transcripts increased by >2-fold during the first 30 min after IFN-γ treatment. An analysis of 109 transcripts identified (including Ch25h) (Table S2) revealed Stat1 as the only transcription factor identified with a combined Z score of >10 and Fisher score of <0.01 (values defined by empirical studies).

Because Stat1 is activated under all three conditions tested (MCMV infection, Ifn-β and Ifn-γ treatment) and multiple potential Stat1 binding sites are present upstream of Ch25h start site (Figures S4B and S4D). We sought to directly test these predictions using a chromatin immunoprecipitation (ChIP) of Stat1-bound DNA from BMDM treated with Ifn-γ for 1 hr (Figure 6I). The ChIP analysis of Ch25h promoter proximal sequences revealed an Ifn-γ-mediated recruitment of Stat1 to the predicted binding region of the Ch25h locus (Figure 6I). To extend this analysis, a ChIP-Seq analysis of histone modifications identified as markers of accessible and active chromatin regions, revealed...
that, in BMDM, the Stat1 binding occurs within a region characterized by these active signatures (Figure 6H). Collectively, these experiments show that Ch25h transcriptional activation is coupled to the interferon response through a direct molecular link with Stat1.

DISCUSSION

The innate immune response and the homeostatic pathways controlling cellular sterol levels are now known to regulate each other reciprocally (Castrillo et al., 2003; Kwak et al., 2000; Weitz-Schmidt et al., 2001). Our present findings demonstrate that Mφ have evolved a program by which IFN is directly coupled to the regulation of 25HC. Although 25HC is a well-known negative feedback mediator of the sterol pathway, we present evidence that it can mediate, at multiple levels, antiviral cellular functions. We show that the mechanism for this coupling is through the direct recruitment of Stat1 to the promoter proximal region of the Ch25h gene. Strikingly, a comprehensive metabolome profiling of oxysterols shows that the classical activated Mφ response is highly focused toward a single oxysterol, 25HC. We find that 25HC can impart antiviral cellular functions via an LXR-independent but Srebp-dependent subordinate mechanism, highlighting a previously unrecognized biological role for 25HC as part of the innate-immune response.

The subordinate involvement of the Srebp pathway for 25HC antiviral activity is based on the following: (1) In normal media, under conditions that reduce the cells reliance on the

Figure 6. 25HC Synthesis Is Interferon-Dependent and Regulated by Stat1; See Also Figure S4 and Tables S1 and S2

(A and B) Ch25h gene expression (relative to mock infected cells) in WT, Ifnb−/− or Ifnar1−/− BMDM infected with MCMV or MCMVdIE3 (MOI = 1).
(C) Changes in intracellular 25HC in Ifnar1 KO BMDM following MCMV infection, Ifn-β (10 U/ml) or Ifn-γ (10 U/ml) stimulation for 24 hr, n = 3; data are mean ± SD.
(D) qRT-PCR analysis of Ch25h mRNA expression at 6 and 24 hpi with MCMV (MOI = 1) or treatment with Ifn-γ (10 U/ml) or Ifn-β (25 U/ml) in WT, Ifnar1−/− or Ifnar1−/− BMDM. n = 3, data are mean ± SD.
(E) Differential nRNA synthesis between 60 and 90 min in Ifn-γ treated (F) or MCMV-infected (H) relative to mock were analyzed and fold-change values in treated or infected cells calculated relative to the control.
(G) WT BMDM treated with Ifn-γ (10 U/ml), Microarray analysis of newly transcribed RNA isolated from 16 successive 30 min windows after treatment.
(H) UCSC genome browser image is shown for Ch25h locus indicating Stat1 binding site (labeled ch25h_8) in promoter region. Normalized tag counts for H3K4me2-MNase ChIP-Seq, H4K5Ac-ChIP-Seq, and H3K4me3-ChIP-Seq are shown for untreated BMDM.
(I) ChIP analysis of Stat1 binding at Igk (negative control), Tap1, and Nos2 (positive controls), and Ch25h loci (as indicated in Figure 5 I) in mock- or Ifn-γ (20 U/ml, 1 hr) treated BMDMs. Fold enrichment for each locus is the ratio of percentage input of Ifn-γ-treated versus mock-treated BMDMs. Igk (negative control) refers to genomic region lacking Stat1 enrichment. Data are representative of two independent experiments performed in duplicate.
Srebp-processing pathway, IC_{50} values obtained are far higher than the known IC_{50} for 25HC inhibition of Srebp processing. (2) An enantiomer of 25HC inhibits viral infection; however, this only occurs at concentrations above 1 μM. We infer from this a Srebp-independent mode of action. (3) The antiviral potency of 25HC viral is dramatically increased for most, but not all, infections under lipid-depleted conditions that favor Srebp processing. Under these conditions, IC_{50} values for 25HC approximate those that actively inhibit the Srebp-pathway. (4) Oxysterols known to target the Srebp-pathway can effectively inhibit viral growth in lipid-depleted conditions, whereas those that do not regulate Srebp fail to affect viral growth. Future studies will be required to further understand the contribution of the Srebp-dependent and independent pathways to 25HC-induced antiviral activity.

How IFN couples with the regulation of the sterol metabolic network is relevant for both innate and adaptive immunity. In recent years, several groups have defined new mechanistic links between the sterol metabolic network and innate (Blanc et al., 2011; Diczfalusy et al., 2009; Im et al., 2011; Liu et al., 2012; Yi et al., 2012) or adaptive (Bauman et al., 2009; Hannedouche et al., 2011) immune responses. Similar to IFN, 25HC is found to halt MCMV growth in M_{φ} cells by impeding postentry viral gene expression. IFN is known to dramatically alter in BMDMs both an increase and decrease in abundance of prenylated proteins (Vestal et al., 1995). One potential pathway for blocking MCMV growth is through altering the mevalonate (isoprenoid) branch of the pathway. Our previous studies had indicated that coincubation of IFN treated infected cells with GGHO partially rescues the antiviral response (Blanc et al., 2011). It is noteworthy that many viruses require prenylation of either viral or host proteins for productive infection (Amet et al., 2008; Bordier et al., 2003; Classe et al., 2003; Gower and Graham, 2001; Wang et al., 2005; Ye et al., 2003). Whether 25HC affects protein prenylation remains to be determined; however, we note that a number of highly specific prenylation inhibitors have been shown to significantly inhibit viral multiplication in vitro and in vivo (Bordier et al., 2003; Glenn et al., 1992; Gower and Graham, 2001; Ye et al., 2003).

In summary, our study demonstrates a previously unrecognized biological role for 25HC as an effector of the early innate interferon response capable of imparting antiviral intracellular functions. Stat1 binding the Ch25h promoter provides a critical molecular link between innate immune stimulation, infection, and the M_{φ} secretion of a single oxysterol, 25HC.

**EXPERIMENTAL PROCEDURES**

**Cell Propagation and Culture**

BMDM were derived from femur and tibia isolated from C57BL/6 mice and grown in DMEM/F12 + Glutamax (Lonza, Vervier, Belgium) supplemented with 10% fetal bovine serum (FCS), 10% L929 conditioned medium (containing colony-stimulating factor CsI) and Penicillin + Streptomycin. FACs assessed BMDMs for M_{φ} cell surface markers, F480 and CD11b. All procedures were carried out under project and personal licenses approved by the Secretary of State for the Home Office, under the United Kingdom’s 1986 Animals (Scientific Procedures) Act and the Local Ethical Review Committee at Edinburgh University. All cultures are routinely tested for mycoplasma and endotoxin levels. Full details for these cultures and for MEFs and cell lines; NIH 3T3, RAW264.7, 199, MDCK, HeLa, MeWo and 293 cells are provided in the Supplemental Experimental Procedures.

**Reported Viruses and Viral Plaque Assays**

Viral growth including plaque assays, reporter GFP, and luciferase assays for viral growth and gene expression measurements for WT MCMV, MCMV-GFP, GLuc-MCMV Murine Gamma herpes virus 68 (MHV-68-GFP), VZV-GFP (vaccine strain Oka), HSV-1-eGFP (C12), A/WSN/33 (H1N1) influenza virus, Ad5-gfp, and Ad19a-gfp are described in Supplemental Experimental Procedures. Plaque reduction assays used an agarose overlay for MCMV, HSV, and Influenza virus infection. For MCMV and HSV, plaque numbers and dimensions were quantified using fluorescent microscopy of infection foci. Phase-contrast and fluorescence visualization of infected was performed using a Zeiss Axios Observer Z1 inverted microscope (Carl Zeiss, Germany). Microscope control and image capture were undertaken using Axiovision Software (Carl Zeiss, Germany). All images were captured and diameters quantified using ImageJ software.

**Metabolic Profiling of Oxysterols**

Details for the extraction of oxysterols and sterols are provided in Supplemental Experimental Procedures. The extracted oxysterol and sterol fractions were derivatized with Girard P reagent and analyzed by LC-MS/MS on a LTQ-Orbitrap Velos. Mass spectra were recorded at high resolution in the Orbitrap analyzer, and MS^3 spectra recorded simultaneously in the LTQ ion-trap. Quantification was performed by stable isotope dilution on reconstructed ion-chromatograms generated in the Orbitrap.

**Microarray Analysis, RNA Labeling, and Isolation from BMDM Cultures**

Incorporation of 4-thiouridine (Sigma) into newly-transcribed RNA including experiments of RNA time course microarray analysis of transcriptional changes in WT, Ifnar^-/-, and Ifnb1^-/- BMDM following MCMV infection and quantitative RT-PCR using tagman primer probe sets (from Applied Biosystems) or for viral transcripts see Supplemental Experimental Procedures. Time course microarray analysis data are compliant with the National Centre for Biotechnology Information Gene Expression Omnibus (GEO) under SuperSeries accession number GSE42505 (SubSeries numbers GSE42503, GSE42504). (GEO, http://www.ncbi.nlm.nih.gov/geo/)

**Statistical Analysis of Transcription Factor Binding Site Overrepresentation**

Entrez gene ID’s for 164 transcripts with a fold change of >2-fold in the Ifn-γ- treated BMDM samples between 0 and 30 min were imported into the oPOSSUM software tool (http://www.cisreg.ca/cgi-bin/oPOSSUM/opossum) and analyzed as described in Supplemental Experimental Procedures.

**Isolation and Quantification of Viral Genome Copy Number by Using qPCR**

For DNA extraction, cells were extensively washed thrice 3 hr postfection and total genomic DNA isolated and genome copy number normalized to input DNA or to gapdh using quantitative procedures described in Supplemental Experimental Procedures.

**Oxysterol Screening against MCMV, HSV-1, MVH-68, VZV, Influenza A, and Adenovirus**

For these experiments, respective host cell systems were conducted in black 96-well plates using media conditions and oxysterol treatment as described in the figure legends and Supplemental Experimental Procedures. The IC_{50} values were calculated as the concentration at 50% viral inhibition. Cell viability and toxicity assays were determined using the CellTiter Blue (CTB, Promega) reagent.

**Metabolite Treatment of Cells**

Murine embryo fibroblasts were infected with MCMV (MOI = 0.01). After adsorption, cells were washed 5 times with normal medium (DMEM, 10% FCS, L-Glutamine and Penicillin/Streptomycin). After washing, normal medium containing vehicle (Ethanol) or 25HC (1 μM) ± Geranylgeraniol (GGOH, 20 μM) (Sigma G3278) or Mevalonolactone (Mev, 20 μM) (Sigma M4667), Farnesol (FOH, 20 μM) (Sigma F203) or Squalene (Sqe, 20 μM) (Sigma S3026) was added to the infected wells. After 4 days, supernatants were collected and MCMV titer calculated by plaque assay.
Computational Prediction of Stat1 Binding Sites in the Ch25h Promoter

To analyze and predict potential Stat1 binding sites in the promoter of Human and Mouse Ch25h genes, we used the open source software Toucan. In brief, 1kb 5’ cis-regulatory regions upstream of the transcriptional start sites of human (ENSG00000138139) or mouse (ENSMUSG00000050370) Ch25h were imported into Toucan. Predicted transcription factor binding sites were then identified in these sequences using the MotifLocater algorithm. Position Weight Matrices for this analysis were derived from the TransFac database V7.0 (public) and the background model used was either mouse or human DBTSS promoters depending on input sequence. A default stringency threshold of 0.9 was used for all predictions.

Chromatin Immunoprecipitation (ChIP)

For ChIP of Stat1, 6 x 10^7 Mø were used per ChIP, as detailed in the Supplemental Experimental Procedures, including the analysis of ChIP-Seq data for UCSC Browser image of Ch25h locus.

SUPPLEMENTAL INFORMATION

Supplemental Information includes four figures, two tables, Supplemental Experimental Procedures, and one movie and can be found with this article online at http://dx.doi.org/10.1016/j.immuni.2012.11.004.
