ABSTRACT:

Intratumoral genetic heterogeneity and the role of metabolic reprogramming in renal cell carcinoma have been extensively documented. However, the distribution of these metabolic changes within the tissue has not been explored. We report on the first-in-human in vivo non-invasive metabolic interrogation of renal cell carcinoma using hyperpolarized carbon-13 (13C) MRI and describe the validation of in vivo lactate metabolic heterogeneity against multi regional ex vivo mass spectrometry. Hyperpolarized carbon-13 (13C)-MRI provides an in vivo assessment of metabolism and provides a novel opportunity to safely and non-invasively assess cancer heterogeneity.

INTRODUCTION

Intratumoral genetic heterogeneity in renal cell carcinoma (RCC) has provided important insights into the evolutionary pathway of RCC tumorigenesis. However, routine analysis of genetic intratumoral heterogeneity has yet to translate usefully into clinical practice as it requires specialized multiregional tumor sampling, complex computational analysis and sequencing platforms.

Metabolic reprogramming is a feature common to many solid tumors. Increased glucose uptake, glycolysis and reduced oxidative phosphorylation, known as the Warburg effect, have been reported in RCC. Hyperpolarized carbon-13 (13C) MRI (HP-MRI) is a novel non-ionizing imaging technique that allows non-invasive real-time analysis of metabolic pathways in vivo. Hyperpolarization using dissolution-dynamic nuclear polarization (DNP) technology provides unprecedented sensitivity for the detection of metabolism of 13C-labeled substrates such as pyruvate, fumarate and glucose in vivo. For example, following administration of 1-[13C] pyruvate, a number of studies have reported on the detection of 1-[13C] lactate
via the reaction catalyzed by lactate dehydrogenase (LDH). This technique has recently been successfully translated into the clinical domain and is a promising tool for disease characterization and therapeutic response monitoring in prostate and brain tumors.5–8

Here, we report on the first-in-human non-invasive metabolic interrogation of RCC using HP-MRI and describe the validation of in vivo lactate metabolic heterogeneity imaged using HP-MRI against multiregional ex vivo mass spectrometry.

METHODS AND MATERIALS
A 72-year-old female with a history of a previous right radical nephrectomy (17 years earlier) for clear cell RCC had an incidental finding of a 6.8 × 5.1 × 6.1 cm mass in the left kidney (Figure 1) confirmed as clear cell RCC.

Histopathological analysis of laparoscopic radical nephrectomy specimen confirmed ISUP/WHO Grade two clear cell RCC (staging pT3a).

The patient provided written informed consent for HP-MRI (Research Ethics Committee (REC) reference number 17/LO/0431) (ClinicalTrials.gov Identifier: NCT03687645) and for tissue based assays (REC reference number 16/WS/0039).

Production of hyperpolarized 1-[13C] pyruvate
Hyperpolarized 1-[13C] pyruvate solution was filled and assembled under aseptic conditions then produced using a DNP polarizer (SPINlab, GE Healthcare, Milwaukee, Wisconsin) and sterilized fluid path.9 The filled sterilized fluid path was bled under aseptic conditions then produced using a DNP hyperpolarizer and the sample, consisting of 1.47 g 1-[13C] pyruvic acid (GMP Precursor from Sigma Aldrich, Vienna, Austria) doped with 15 mM AH111501 electron paramagnetic agent, underwent microwave irradiation for approximately 2 h to achieve a polarization of 31.9%. The sample was then dissolved in 38 ml of sterile water and neutralized with 17.5 ml 460 mm, field of view (coronal) = 369 mm x 460 mm, echo train length = 15, number of slices = 30, Field of view (coronal) = 369 mm x 460 mm, echo train length = 15, number of signal averaging = 1.

The i.v. line was connected to an automatic dual chamber power injector with the first chamber (chamber A) programmed to deliver hyperpolarized 1-[13C] pyruvate solution at a rate of 5 ml s⁻¹. The second chamber (chamber B) was pre-loaded and programmed to deliver 20 ml of normal saline flush immediately after hyperpolarized solution injection.

Anatomical localization of the renal tumor was performed on axial and coronal $T_2$ weighted imaging. A turbo spin echo sequence was utilized with the following parameters: repetition time = 5400 ms, effective echo time = 111 ms, slice thickness = 3 mm, number of slices = 30, Field of view (axial) = 203 mm x 460 mm, field of view (coronal) = 369 mm x 460 mm, echo train length = 15, number of signal averaging = 1.

Following localization of the tumor, a central axial imaging slice was planned under the direction of a board certified radiologist for subsequent 13C imaging.

Hyperpolarized MRI
40 ml of hyperpolarized 1-[13C] pyruvate was injected at a rate of 5 ml s⁻¹ followed by a flush of 20 ml of normal saline at 3 ml s⁻¹. Repeated 13C chemical shift imaging (CSI) measurements were performed (repetition time = 80 ms, time of echo = 3 ms, flip angle = 10°, bandwidth = 10,000 Hz, field of view = 120 mm x 120 mm, slice thickness = 30 mm, acquisition matrix = 16 x

Table 1. Release criteria for sterile hyperpolarized solution in Medrad syringe for injection

| Parameter                        | Criteria                                      |
|----------------------------------|-----------------------------------------------|
| Appearance                       | Clear colorless solution with a slightly green tinge and free from visible particles |
| Sterility                         | Sterility: Complies with Ph. Eur. Endotoxins: Complies with Ph.Eur. |
| Physical & chemical parameters    | Based on UCSF Limits                          |
| 13C nuclear polarization          | Not Less Than 10.0%                           |
| Pyruvate                          | 220–280 mM                                    |
| Residual AH111501                 | Not more than 3.0 µM                          |
| pH (i) QC module                  | 6.5–8.5                                       |
| Δ (i) & (ii)                      | 6.5–8.5                                       |
| Drug product temperature          | 25.0 – 37.0°C                                 |
| Drug product volume               | >38 ml                                        |
| Compliance with TSE regulations   |                                               |

TSE, transmissible spongiform encephalopathies.

Tissue handling
After macroscopic pathology review, multiregional tissue samples were collected within 30 min of nephrectomy. A 1 cm thick axial slice of kidney was selected at the level of the renal hilum (visually matched to the MRI CSI imaging slice) and regional sampling was labelled sequentially (10 samples of tumor, and 5 samples of adjacent non-tumorous kidney tissue). Samples were placed in cryo-vials and immediately snap frozen with liquid nitrogen. Samples were formalin fixed, processed in paraffin and stained with hematoxylin & eosin after sectioning for microscopic confirmation of presence or absence of malignancy.

Lactate measurement by liquid chromatography-mass spectrometry
Frozen tissue samples were weighed into Precellys tubes prefilled with ceramic beads (Stretton Scientific Ltd., Derbyshire, UK), and an exact volume of extraction solution (30% acetonitrile, 50% methanol and 20% water) was added to obtain 40 mg specimen per mL of extraction solution. Samples were lysed using a Precellys® 24 tissue homogeniser (Bertin Corp, Rockville, MD. 5500 rpm 15 s x 2) and then centrifuged (16,162 x g for 10 min at 4°C). The supernatant was transferred to glass vials (Microsolv, Inc., Natick, MA) and stored at −80°C until LC-MS analysis.

Samples were randomized in order to avoid bias due to machine drift and the operator was blind to the HP-MRI assessment. LC-MS analyses were performed on a Q Exactive mass spectrometer (Thermo Fisher Scientific) mass spectrometer coupled to an Ultimate 3000 RSLC system (Dionex). The liquid chromatography system was fitted a ZIC-pHILIC column (150 × 2.1 mm) and respective guard (20 × 2.1 mm) (all Merck Millipore, Germany), and metabolites were eluted with the previously described gradient.10 The mass spectrometer was operated in full MS and polarity switching mode. The acquired spectra were analyzed using XCalibur Quan Browser software (Thermo Fisher Scientific). Absolute quantification of lactate was performed by interpolation of the corresponding standard curve obtained from serial dilutions of a commercially available standard (Sigma Aldrich, Vienna, Austria) running with the same batch of samples. LC-MS analysis confirmed heterogeneous lactate levels within tumor samples (Figure 2b, samples 1–10), as depicted on the bar chart in Figure 3. The highest level of lactate by mass spectrometry (Figure 3—red bar) was found in region 5, corresponding to the region displaying the highest 1-[13C] lactate signal in the HP-MRI scan (Figure 2—red arrow). Further 1-[13C] lactate formation was observed at imaging corresponding to samples 8–9 (Figure 3a—orange bars) and sample 1 (Figure 3a—yellow bar).

Overall, we observed heterogeneity of HP-MRI 1-[13C] lactate signal generally conforming to the heterogeneity found at mass spectrometry metabolic analysis.
Hyperpolarized carbon-13 (13C) MRI is a novel non-invasive metabolic assessment of RCC using 1-[13C] pyruvate HP-MRI and validate the results with ex vivo multi regional LC-MS analysis.

HP-MRI using dissolution DNP produces a dramatic signal enhancement, allowing real-time imaging of metabolic pathways. Until now, the clinical application of HP-MRI in malignancies has been limited to prostate cancer and brain tumors. To the best of our knowledge this study represents two novel factors: it is the first-in-human 1-[13C] pyruvate HP-MRI study in RCC, and it is the first HP-MRI study with tissue assay validation.

Unlike the multiregional sampling used for tissue-based assessment of genetic and metabolic heterogeneity, HP-MRI provides a non-invasive technique that can be repeated over time and thus could be used for longitudinal tumor monitoring.

It has been previously shown that the pyruvate signal build-up precedes the lactate signal build-up in the time course data of pre-clinical animal models, consistent with the notion that the pyruvate signal reflects its delivery to the tissue and cells whilst the lactate signal reflects pyruvate-to-lactate conversion catalyzed by lactate dehydrogenase in the glycolytic pathway.

In our patient, the regional distribution of pyruvate and lactate differed markedly across the RCC, suggesting that blood flow and metabolism were not integrally linked within the cancer. One possible explanation for our observation is that higher levels of LDH are found in areas of tumor which exhibit hypoxia. Tumor hypoxia can be caused by high levels of metabolic activity or through relative decrease in effective blood flow. Hence low 1-[13C] pyruvate signal, reflecting limited blood flow, may occur together with high 1-[13C] lactate signal, reflecting increased metabolic activity.

We also observed heterogeneity of in vivo 1-[13C] lactate signal across the tumor confirmed by ex vivo mass spectrometry. Genomic, microstructural and macrostructural heterogeneity has been noted in cancers including RCC. Our results confirm heterogeneous metabolic activity is also present within RCC. Future work linking genomic, metabolic, microstructural and macrostructural changes is needed to explore if RCC metabolic heterogeneity relates to genomic heterogeneity; and, whether metabolic heterogeneity is a result of micro/macrostructural heterogeneity or conversely results in RCC micro/macrostructural heterogeneity.

The CSI sequence used within this study enabled single slice imaging with limited temporal resolution. New sequences are being developed for hyperpolarized 13C metabolic imaging allowing full anatomical coverage and improved temporal resolution.

HP-MRI has a variety of potential clinical applications. For example, knowledge of RCC metabolic activity may provide a prognostic tool to help treatment stratification, such as whether active surveillance or urgent surgery is warranted. Temporal changes in metabolism could be used to monitor patients on active surveillance, and to provide an assessment of treatment response. Indeed, identifying areas of higher metabolic activity within solid tumors in general could help guide target biopsy and themselves act as targets for novel focal therapies.

Learning points

1. Metabolic reprogramming is a feature common to many solid tumors with increased glucose uptake, glycolysis and reduced oxidative phosphorylation (Warburg effect) reported in RCC
2. Hyperpolarized carbon-13 (13C) MRI is a novel non-ionizing imaging technique that allows non-invasive real-time analysis of metabolic pathways in vivo.
3. We report on the first-in-human in vivo non-invasive metabolic assessment of RCC using 1-[13C] pyruvate HP-MRI and validate the results with ex vivo multiregional liquid chromatography–mass spectrometry analysis.
4. The regional distribution of pyruvate and lactate differed markedly across the RCC, suggesting that blood flow and metabolism were not integrally linked within the cancer.
5. Knowledge of RCC metabolic activity using hyperpolarized carbon-13 (13C) MRI may provide a future prognostic tool to help treatment stratification.
FUNDING
This study was funded by the Medical Research Council, Kidney Cancer UK and Facing up 2 Kidney Cancer. AL was supported by a Cancer Research UK/ Engineering and Physical Sciences Research Council (CRUK/EPSRC) award (C1519/A10331 and C1519/A16463) from the University College London/King’s College London (UCL/KCL) Comprehensive Cancer Imaging Centre (CCIC). MGBT receives funding from Kidney Cancer UK and Facing Up to Kidney Cancer. JBN receives funding from the Medical Research Council. ASHC and CF are supported by the Medical Research Council. Core award to the MRC Cancer Unit (MRC_MC_UU_12022/6). ME receives research support from the United Kingdom’s National Institute of Health Research (NIHR) UCLH/UCL Biomedical Research Centre. He has been an NIHR Senior Investigator since 2013. Part of this work was undertaken at the Comprehensive Biomedical Centre (BRC), University College London Hospitals NHS Foundation Trust (UCLH), which received a proportion of the funding from the National Institute for Health Research (NIHR). The views expressed in this publication are those of the authors and not necessarily those of the UK Department of Health.
