Inverse-electron-demand Diels–Alder (iEDDA) cycloaddition between 1,2,4,5-tetrazines and strained dienophiles belongs among the most popular bioconjugation reactions. In addition to its fast kinetics, this cycloaddition can be tailored to produce fluorescent products from non-fluorescent starting materials. Here we show that even the reaction intermediates formed in iEDDA cycloaddition can lead to the formation of new types of fluorophores. The influence of various substituents on their photophysical properties and the generality of the approach with use of various trans-cyclooctene derivatives were studied. Model bioimaging experiments demonstrate the application potential of fluorogenic iEDDA cycloaddition.

Bioorthogonal reactions are a set of chemical transformations that enable labeling and study of biomolecules under native biological conditions.[1] The properties of these reactions include, among other beneficial factors, high degrees of selectivity, fast kinetics, formation of stable covalent products, and compatibility with strict biological conditions. A number of reactions featuring these attributes are currently available and they have been developed into valuable tools in biology, chemical biology, materials sciences, and biomedical research.[2]

One especially useful property of bioorthogonal reactions is fluorogenicity. This attribute is based on the production of fluorescent products from nonfluorescent starting materials, thus providing a convenient means of detection through the production of a fluorescent signal.[3] There are several ways in which this can be achieved. One is based on quenching of fluorescence through intramolecular energy transfer in bioorthogonal fluorophores conjugates. The subsequent reaction provides products as different chemical species, and this leads to restoration of the fluorescence of the attached fluorophore. One prominent example of a class of reagents of this type is that of 1,2,4,5-tetrazines.[4]

Another, comparably rare, example of a fluorogenic reaction is based on the formation of a fluorophore as a result of reaction between two non-fluorescent bioorthogonal reagents. An example belonging to this class of fluorogenic reactions is the formation of fluorescent pyrazolines through reaction between nitrile imines and various dipolarophiles.[5]

We recently discovered that pyridinium 1,2,4-triazines containing a push–pull substitution pattern also form fluorescent products in reaction with strained trans-cyclooctenes (TCOs).[6] In addition, we and others have reported that reactions between 1,2,4,5-tetrazines and particular dienophiles also lead to fluorescent products without the need for attachment of an extra fluorophore moiety.[7] Despite successful application of this chemistry for bioimaging, we found that only the axially substituted hydroxy trans-cyclooctene and azabicyclononene(dienophiles afforded fluorescent dihydroxytripyrizine products. This limited scope of dienophiles suitable for fluorogenic labeling hampers broader utility of the methodology. An alternative and more general approach is hence desirable. In continuation of our work in this direction we show here that by using 1,2,4,5-tetrazines containing specific electron-donating substituents it is possible to extend the fluorogenic tetracyclic adduct to other dienophiles. We have characterized the photophysical properties of the reaction products and in this sense evaluated the effects of various substituents on the tetrazine core, as well as the influence of the TCO structure. In addition, we show that the inherent fluorogenic nature of the chemistry is also operative under biological conditions and can be applied for bioimaging.

The first reaction step of inverse-electron-demand Diels–Alder (iEDDA) cycloaddition between a 1,2,4,5-tetrazine and a dienophile involves the formation of a tetraazabicyclic system, which, after a retro-Diels–Alder reaction and extrusion of molecular nitrogen, is transformed into a 4,5-dihydroxypyrizidine (Figure 1A). This can further isomerize to the corresponding 1,4-dihydroxypyrizidine through, for example, addition and elimination of a water molecule or alternatively through intramolecular interaction with an appropriately placed heteroatom substituent on the TCO.[8,9] The initially formed 4,5-dihydroxypyrizidine heterocyclic core is a unique π-conjugated system formed upon reaction between tetrazines and all TCO derivatives. Therefore, we thought that it offers an exclusive opportunity to be used for potential formation of fluorophores. Indeed, during experimentation with various 1,2,4,5-tetrazines we...
found that tetrazine derivative 1a, bearing a p-dimethylamino substituent, forms a fluorescent product when combined with equatorially hydroxy-substituted TCO 2a (eqTCO). As we have previously reported,[7b] the same derivative leads to fluorescent products, with different photophysical properties, upon reaction with the corresponding axially hydroxy-substituted TCO 2b (axTCO, Figure 1 Band C). We ascribed the formation of the two different fluorescent species to the production of different tautomers of the dihydropyridazine core (Figures S1 and S2 in the Supporting Information). The structure of the central dihydropyridazine heterocycle thus influences the photophysical properties of the products, enabling control over the outcome of the reaction by simply changing the configuration of the starting TCO. This interesting behavior prompted us to explore the phenomenon in more detail.

We first synthesized a series of tetrazine derivatives by the Heck cross-coupling methodology developed by Devaraj and co-workers[4b] and measured the photophysical properties of the products formed after reaction with eqTCO (Table 1).

The derivative formed from the tetrazine 1b, bearing a methoxy substituent, was found to be non-fluorescent. This indicates that the weaker electron-donating ability of the methoxy group is not sufficient to promote formation of the fluorophore. On the other hand, the presence of a phenyl or thiophene moiety at position 6 in the tetrazine structure, in combination with a dimethylamino substituent (tetrazines 1a and 1c), led to the formation of fluorophores with higher fluores-

| R¹ | R² | λ_a (nm) | λ_em (nm) | Δλ | φ_r (%) | Φ_r [%] | Intensity Increase |
|----|----|---------|----------|----|--------|--------|------------------|
| a  | –  | 545     | 628      | 83 | 0.55   | 13-fold |
| b  | –  | 295     | –        | –  | –      | –      | –                |
| c  | –  | 546     | 626      | 80 | 0.52   | 18-fold |
| d  | –  | 546     | 626      | 80 | 0.45   | 10-fold |
| e  | –  | 566     | 643      | 77 | 0.21   | threefold |
| f  | –  | 549     | 626      | 77 | 0.47   | 12-fold |

[a] Absorption and emission maxima were measured in CH₃CN/H₂O 1:1. 
[b] Relative fluorescence quantum yields were determined by using Nile Red in methanol as standard.
cence quantum yields. The enhancement of the fluorescence signals after the iEDDA click cycloaddition reached 13- and 18-fold for the phenyl- and the thiophene-substituted tetrazines, respectively (Figures 2 and S3–S8, Tables 1 and S2).

A recent literature example prompted us to explore the possibility of introducing an azetidin moiety as an alternative electron-donating substituent; this had been shown to improve the photophysical properties of some xanthene dyes.\[10\]

We also varied the substituent on the other side of the tetrazine and introduced phenyl, thiophene, and pyridyl groups at position 6. Surprisingly, the iEDDA cycloaddition between the pyridyl-substituted tetrazine 1e and eqTCO provided only modestly increased fluorescence (Table 1). Possibly, the presence of an electron-withdrawing substituent (pyridyl) at this position is not beneficial for fluorescence generation and/or other quenching mechanisms are responsible for the observed lower fluorescence. By comparing the absorption and emission maxima of all derivatives it can be concluded that none of these substituents influence the absorption and emission maxima to any great extent. Although the fluorescence quantum yields of the fluorophores formed in the reactions are rather low, their photophysical properties enabled successful use in bioimaging application, as we show below.

An important aspect of bioconjugation reactions is the reactivity of the reagents, which are usually used at low-micromolar concentrations. Accordingly, we determined the second-order rate constants of iEDDA cycloaddition between tetrazines 1a–f and the eqTCO 2a (Table S1). All of the tetrazines reacted with this dienophile, displaying second-order rate constants of approximately 7 m\(^{-1}\) s\(^{-1}\) in a 1:1 mixture of CH\(_3\)CN and H\(_2\)O at room temperature. For purposes of comparison, we also determined the second-order rate constants of cycloaddition between the same tetrazines and the axTCO 2b. Our data are in good agreement with previous observations in which the equatorial isomer was found to react four to five times more slowly than the corresponding axial isomer (Table S1).\[11\]

As mentioned above, the 4,5-dihydropyridazine system is an intermediate in the iEDDA reaction. Depending on the TCO structure and the environment (e.g., presence of water), it can further isomerize to the corresponding 1,4-dihydropyridazine (Figure 1A). This means that the fluorescence of the initially formed 4,5-dihydropyridazine should decrease over time as the tautomerization proceeds. This decrease in fluorescence is an important factor for potential application in, for example, bioimaging. Consequently, we measured the decay in the fluorescent signal over time for tetrazine derivatives 1c and 1f (Figures 3, S9, and S10).

Our data show that the fluorescence of the click products persists over hours with a half-life of about two hours, almost completely disappearing within one day. Concomitant appearance of the fluorescence of the newly formed 1,4-dihydropyridazine tautomer was detected after this time period (Figures S9 and S10). In addition, formation of a small amount of the fully oxidized pyridazine product was observed by HPLC-MS analysis (Figure S1). This product can also partially contribute to the observed decay in the fluorescent signal. Although

**Figure 3.** The decay in fluorescence signals over time for the click products formed from eqTCO 2a and tetrazines 1c and 1f.
this enables only temporary labeling, the timescale is sufficient for bioimaging applications (see below).

To study the scope of the fluorogenic reaction we tested a series of TCOs\textsuperscript{[12]}—2c to 2f—for their propensity to form fluorescent products with tetrazines 1c and 1f (Figures 4, S11, and S12, Tables 2, S3, and S4). We found that all TCOs tested gave rise to the formation of fluorophores with similar photophysical properties to those observed with the eqTCO 2a. The only exception was the dioxolane-fused TCO 2f, which provided a less pronounced fluorescence enhancement of only sixfold. The absorption and emission maxima of all derivatives were similar, being centered around 550 nm and 630 nm, respectively. These data demonstrate that the formation of 4,5-dihydropyridazines in cycloadditions between tetrazines and TCOs can be considered a more general approach for the development of fluorogenic reactions based on this type of chemistry.

We next performed a series of experiments to test whether we could apply these fluorogenic reactions for bioimaging. We first prepared triphenylphosphonium-functionalized TCO (TPP-TCO). The TPP moiety is known to target various cargoes to mitochondria\textsuperscript{[13]} and thus enables organelle-specific intracellular labeling. We incubated live HeLa cells with 5 \(\mu\)M TPP-TCO for 15 min, then washed the cells to remove any excess of the probe, and finally added 5 \(\mu\)M tetrazine 1c to initiate the fluorogenic reaction. We observed the formation of a marked fluorescence signal inside the cells after only 5 min incubation, thus indicating good cell permeability of probe 1c and confirming successful reaction. Co-staining with commercially available mitochondrion-specific MitoTracker Deep Red dye further confirmed specific labeling of this organelle (Figures 5A and S13). The fluorescent signal was still detectable even after 2 h, in good agreement with our previous time-lapse fluorescence-decay experiments.

### Table 2. Absorption and emission maxima [nm] and fluorescence enhancement of the products formed in reaction of 1c/1f with different TCOs.

| Tetrazine | 1c | 1f |
|-----------|----|----|
| 547/627   | 550/627 | 547/631 | 558/638 |
| Fl. intensity increase | 13-fold | 14-fold | 11-fold | sixfold |
| 550/627   | 550/627 | 550/631 | 551/631 |
| Fl. intensity increase | ninefold | ninefold | eightfold | fourfold |

![Figure 4. Fluorescence enhancement of the reaction between tetrazines 1c/1f and different TCOs.](image)

![Figure 5. Confocal microscope images from fluorogenic live cell labeling.](image)
To examine the potential of the fluorogenic reaction for bioimaging further, we also conjugated the TCO moiety to concanavalin A (ConA-TCO). Concanavalin A is a lectin with high specificity for α-d-mannose- and α-d-glucose-containing glycoconjugates. After incubation of live HeLa cells with ConA-TCO and addition of tetracene 1c, specific cell membrane labeling was observed by confocal fluorescence microscopy, whereas cells treated only with ConA-TCO were not fluorescent (Figures S8 and S14). These experiments demonstrate that the fluorogenic nature of the cycloaddition is well preserved under biological conditions and can be used for intracellular labeling as well as for fluorescent labeling of cell membrane compartments.

In conclusion, we have shown that the 4,5-dihydropyridazine reaction intermediate is a unique structural motif that can be utilized for the formation of fluorescent products in iEDDA cycloaddition between 1,2,4,5-tetrazines and trans-cyclooctenes. Tetrazines containing electron-donating dimethylamino or azetidine groups form fluorescent products upon treatment with various TCIs. The fluorogenic nature of the cycloaddition enables application for bioimaging, as we have shown by fluorogenic labeling of intracellular compartments and cell membrane glycoconjugates.
