Abstract
We have cloned the Yarrowia lipolytica TPS1 gene encoding trehalose-6-P synthase by complementation of the lack of growth in glucose of a Saccharomyces cerevisiae tps1 mutant. Disruption of YITPS1 could only be achieved with a cassette placed in the 3’ half of its coding region due to the overlap of its sequence with the promoter of the essential gene YITFC1. The Yltps1 mutant grew in glucose although the Y. lipolytica hexokinase is extremely sensitive to inhibition by trehalose-6-P. The presence of a glucokinase, insensitive to trehalose-6-P, that constitutes about 80% of the glucose phosphorylating capacity during growth in glucose may account for the growth phenotype. Trehalose content was below 1 nmol/mg dry weight in Y. lipolytica, but it increased in strains expressing YITPS1 under the control of the YITEF promoter or with a disruption of YALI0D15598 encoding a putative trehalase. mRNAs levels of YITPS1 were low and did not respond to thermal stresses, but that of YITPS2 (YALI0D14476) and YITPS3 (YALI0E31086) increased 4 and 6 times, respectively, by heat treatment. Disruption of YITPS1 drastically slowed growth at 35°C. Homozygous Yltps1 diploids showed a decreased sporulation efficiency frequency that was ascribed to the low level of YALI0D20966 mRNA an homolog of the S. cerevisiae MCK1 which encodes a protein kinase that activates early meiotic gene expression.

Introduction
Trehalose, a non-reducing disaccharide formed by two glucose units, has important and varied functions in different organisms [1,2]. In yeasts trehalose is synthesized by a two-step pathway [3]: first, trehalose-6-phosphate (T6P) is formed from glucose-6P and UDP-glucose by the enzyme T6P synthase (Tps1) encoded by the TPS1 gene [4] and then dephosphorylated by a T6P phosphatase (Tps2) encoded by the gene TPS2 [5]. Two other proteins without catalytic activity, Tps3 and Tsl1, appear to form a complex with Tps1 and Tps2 [6]. Mutations in the genes involved in trehalose biosynthesis affect glucose metabolism, morphology or virulence in yeasts and fungi [2], cause lethal phenotypes in insects and nematodes [7,8] and are embryo lethal or affect inflorescence branching and other structures in plants [9]. In Saccharomyces cerevisiae or Kluyveromyces lactis mutations in the gene TPS1 caused inability to grow in glucose [4,10,11]. This phenotype has been ascribed to the loss of the inhibitory effect of T6P on hexokinase [2,12] and mathematical modeling of glycolysis has confirmed the importance of this control mechanism in S. cerevisiae [13]. The inhibition of hexokinase by T6P is widespread among yeasts [12,14] but its strength is variable; the most inhibited hexokinase reported is that of the yeast Yarrowia lipolytica with a $K_i$ of 3.5 µM [12,15]. Y. lipolytica is a dimorphic yeast that separated early from the yeast evolutionary trunk [16]. It has attracted attention due to its ability to shift between a yeast and an hyphal form [17] to excrete organic acids [18,19] and to its potential as host for expression of heterologous proteins [20]. Y. lipolytica is also being used as model to study physiological processes like lipid accumulation [21] or peroxisome biogenesis and pexophagy [22]. Differences in kinetic or regulatory properties of important Y. lipolytica enzymes [23,24,25] and in transcriptional regulation of some of its genes with respect to those found in S. cerevisiae [26,27] have been described. Therefore due to the high sensitivity of Y. lipolytica hexokinase to T6P it appeared worthwhile to isolate the TPS1 gene of this yeast and to analyze the effects of its disruption. The isolation of this gene presents also a potential technological interest as in Aspergillus niger the degree of expression of the tps4 gene that encodes T6P synthase, influences the rate of citric acid production [28,29] and Y. lipolytica excretes this acid in some conditions [18,19]. We report here that Y. lipolytica has a single gene encoding T6P synthase, that its disruption does not preclude growth in glucose but decreases sporulation efficiency and slows down growth at 35°C. In addition we report that disruption of YITPS3 abolishes the increase of trehalose observed during heat shock.

Materials and Methods
Strains and culture conditions
The yeasts strains used are shown in Table 1. Y. lipolytica was cultured in a synthetic medium with 0.17% yeast nitrogen base
without amino acids and ammonium sulfate (Difco, Detroit, MI) and 0.1% glutamate pH 6. *S. cerevisiae* was cultured similarly but using ammonium sulfate as nitrogen source. Auxotrophic requirements were added at a final concentration of 20 μg/ml and 2% glucose was generally used as carbon source. Liquid cultures were shaken at 30°C. Sporulation medium was based in commercial V8 drink essentially as [30]. Freshly constructed diploid strains were patched on this medium and incubated at 25°C for up to two weeks. Sporulation was followed by malachite green staining [31]. Spores were recovered from sporulated cultures from 30°C to a shaking water bath at 40°C or at 4°C and keeping them for the time indicated in each experiment. Temperature equilibration took place in less than five minutes.

Libraries, primers and plasmids

A *Y. lipolytica* cDNA library under the control of the *S. cerevisiae* PGK1 promoter in plasmid pFL61 [32] and a genomic library of *Y. lipolytica* [33] were used. Yeast transformations were as described in [34] for *Y. lipolytica* and in [35] for *S. cerevisiae*. Primers used in PCR reactions are shown in Tables S1 and S2. All PCR products were sequenced to verify their identity.

The following plasmids for *S. cerevisiae* were constructed:
- pCLF1 carrying the YITPS1 gene was isolated from a cDNA library [32] by its ability to complement the lack of growth in glucose of a *S. cerevisiae* *tps1* strain.
- pCLF2, a centromeric plasmid that carries *YITPS1*, was constructed as follows. The BamHI fragment from plasmid pAN10 [36] carrying the promoter and the terminator regions of the *S.cerevisiae TPS1* was inserted into pRS316 [37] linearized with BamHI. A 1.5 kb blunt-ended *NotI* fragment with *YITPS1* from pCLF1 was inserted in the blunt-ended HindIII site of this plasmid.
- pCLF7 expresses *YITPS3* under the control of the *ScADH1* promoter. *YITPS3* (YALI0E31086) is annotated as an intron containing gene. Using the FirstChoice RLM-RACE Kit (Ambion) we checked the correctness of the ATG and the cDNA predicted sequence. Primer design to amplify the cDNA from genomic DNA was based on the fact that the first exon is only 23 bp long. Primer 1006 covers the first exon and the first 19 bp of the second exon; together with primer 1007 produced a PCR product of 3168 bp containing the cDNA of *YITPS3*. This product was cloned in the pCR-Blunt vector (Invitrogen) and the resulting plasmid was digested with *NotI* and *SpeI* blunt-ended and cloned in pDB20 [38] in which the *URA3* marker had been substituted by *LEU2*. The cDNA of *YITPS3* was sequenced again when introduced in this plasmid.

Plasmids pCLF are described in Materials and Methods.

http://dx.doi.org/10.1371/journal.pone.0023695.t001
The following plasmids for *Y. lipolytica* were constructed:

- pCLF3 carries a fragment of 5.4 kb that contains the *Y. lipolytica* TPS1 gene and was isolated by screening a *Y. lipolytica* genomic library [33] with a *YTPS1* probe.
- pCLF4 expresses *YTPS1* under the control of its own promoter. It was constructed as follows: the *YURA3* marker in plasmid pCL49 [26] was substituted by *YIL126W* to give pCL49L. The *SphI-BamHI* fragment of pCL49L was replaced by a 2.8 kb *HpaI-BamHI* fragment from pCLF3 bearing the *YTPS1* ORF and 1 kb of upstream sequence.
- pCLF5 carries the coding region of *YTPS1* (a 1.5 kb *NdiI* fragment) from plasmid pCLF1 under the control of the *YTEF1* promoter in plasmid pCL49L.
- pCLF8 carries a fusion of the *YTPS1* promoter to *lacZ*. A 1214 bp DNA fragment that includes the initial amino acids of *YTPS1* was obtained by PCR, using oligonucleotides 1010 and 1011 cloned into pGEM-T easy, digested with *NdeI* and *BamHI* and inserted into plasmid pNA354B [39] digested with the same enzymes. The resulting plasmid was linearized with *ApaI* to direct integration into the *YIL126W* locus. Correct integration was checked by PCR and Southern analysis.
- pCLF9 carries the coding region of *S. cerevisiae* TPS1 obtained by PCR using primers 1012 and 1013 in plasmid pCL49L.

**Disruption of *YTPS1***

In two consecutive PCR reactions a 1-*SacI* restriction site and a deletion of 658 bp were created. Primers 1001 and 1002 with complementary ends including the recognition site of meganuclease I-*SacI*, 1000 and 1003 were used. With pCLF3 as template and the mentioned primers two fragments corresponding to the 5’ and 3’regions of the disruption cassette were obtained. These products were used as template with primers 1000 and 1003 in a PCR reaction to obtain a disrupted *YTPS1* copy. The product was cloned into pGEM-T easy, digested with I-*SacI* and ligated to a 1.2 kb *HindIII* fragment flanked by I-*SacI* sequences from plasmid pINA62 [41]. The 5268 bp fragment *NdiI* was used to disrupt the chromosomal copy of *YTPS1* gene.

**Disruption of *YTPS3*** (YALI0E31086)

A piece of 3611 bp containing the *YTPS3* gene was obtained by PCR from genomic DNA and primers 1004 and 1005 and cloned in pGEM-T easy (Promega). The resulting plasmid was digested with *XhoI*, to remove a fragment of 758 bp, and ligated to a 2.1 kb *SalI* fragment containing the *YIL126W* gene. The *NdeI* digestion of the plasmid pINA62 [41] after filling-in the ends of both DNA segments. The chromosomal copy of *YTPS3* was disrupted using a 4996 bp *NdiI* fragment from the previous plasmid. Correct disruption was checked by PCR.

**Disruption of *YINTH1*** (YALI0D15598)

A fragment of 2049 bp containing YALI0D15598 [42] encoding a putative neutral trehalase (*YINTH1*) was obtained by PCR using primers 1008 and 1009 and cloned in pGEM-T easy. The resulting plasmid was digested with *XhoI* and *XhiI* to substitute an internal 816 bp fragment of the *YTH1* gene with a 2.1 kb fragment containing the *YIL126W* gene from plasmid pINA62 [41] digested with *NdeI*. A 3342 bp *NdeI* fragment from this construction was used to disrupt the chromosomal copy. Correct disruption was checked by PCR and Southern analysis.

**RT-qPCR**

Total RNA from *Y. lipolytica* was extracted from flash-frozen cells [43] and processed as described therein. The quality of RNA was checked using the Agilent 2100 Bioanalyzer. The primers for RT-qPCR are shown in Table S2. They were checked for specificity using the Primer-BLAST from NCBI against the *Y. lipolytica* CLIB122 genomic sequence. Total RNA was reverse-transcribed into cDNA using the High Capacity RNA-to-cDNA Master Mix (Applied Biosystems). The cDNA levels were then analyzed using a LightCycler 480 from ROCHE and the LightCycler 480 SYBR Green I Master mix (Roche) with each primer at 250 nM. Each sample was tested in triplicate. After completion of the RT-qPCR melting-curve data were collected to verify PCR specificity, the absence of contamination and primer dimers. The gene YALI0F27533 (ARP4) was used to normalize the data.

**Extracts and assay of enzymatic activities**

Cell free extracts were prepared by breaking the yeasts in buffer with glass beads in six cycles of 1 min of vortexing and 1 min on ice. The buffer was 20 mM imidazole pH 7, with the addition of 1 mM DTT and 1 mM EDTA when T6P synthase was assayed. The extract was centrifuged in the cold for 15 min at 13000 rpm in an Eppendorf table top centrifuge and the supernatant used for determination of enzyme activities. T6P synthase activity was determined by a two step method [3] in a mixture of 50 mM imidazole pH 7, 0.1 M KCl, 10 mM MgCl₂, 1 mM EDTA, 10 mM glucose 6-P and 5 mM UDP-glucose. Samples were taken at different time intervals and boiled for 3 minutes to stop the reaction. The UDP formed was measured spectrophotometrically in a coupled assay with NADH, pyruvate kinase and lactate dehydrogenase. A blank without added glucose-6P was run in parallel for each sample. Hexokinase and glucokinase were assayed with glucose and fructose as in [15]. β-galactosidase was assayed in 80 mM sodium phosphate buffer, 8 mM KCl, 0.8 mM MgSO₄, 40 mM β-mercaptoethanol, and 2.6 mM 2-nitrophenyl β-D-galactopyranoside as described by Wallenfels [44]. Protein was assayed with the commercial BCA protein assay kit (Pierce).

**Trehalose determination**

The cultures were harvested by centrifugation, washed with water and frozen until use. Trehalose was extracted with boiling water as described in [45]. Trehalose was determined enzymatically using the Trehalose assay Kit from Megazyme (Bray, Co. Wicklow, Ireland).

**Extraction and assay of intracellular metabolites**

Yeast cells were quickly filtered through a Millipore AAWPO4700 and snap frozen in liquid nitrogen. The frozen pellets were dropped in boiling ethanol and treated as in [46]. Metabolites were determined spectrophotometrically as in [47]. For calculations, it was assumed that 1 g wet yeast has an intracellular volume of 0.6 ml [48].

**Nucleotide accession number** - The sequence of the *YTPS1* cDNA was deposited at the GenBank database with the accession number AJ011032.

**Results**

Cloning and characteristics of the *Y. lipolytica TPS1* gene

We used the phenotypic complementation of the absence of growth in glucose of a *S. cerevisiae* tps1 mutant [2,49] to isolate the *TPS1* gene from *Y. lipolytica*. We transformed a *S. cerevisiae* tps1 mutant strain with a cDNA library from *Y. lipolytica* under the
control of the *S. cerevisiae* PGK1 promoter (see Materials and Methods) and selected transformants that grew on glucose. Plasmid pCLF1 isolated from different transformants carried a DNA insert of about 1.5 kb whose sequence encodes an ORF encoding a putative protein of 469 amino acids that shares about 60% identity with different fungal T6P synthases. This *Y. lipolytica* cDNA inserted either in a multicopy or in a centromeric plasmid not only complemented the glucose negative phenotype of the *S. cerevisiae* tps1 mutant but also restored its ability to synthesize trehalose (Figure 1). These results indicate that the DNA cloned encodes a bona fide Tps1 protein from *Y. lipolytica* that is functional in *S. cerevisiae*. We will refer to the gene encoding that protein as *YITPS1*. The 1 kb upstream region of *YITPS1* contains a CCCC1 motif [50] that in *S. cerevisiae* is implicated in heat and other stress-controlled transcription [51,52,53,54]. About 215 bp upstream of the ATG of *YITPS1* we found the ATG of an ORF whose transcription runs divergent to that of *YITPS1* (Figure 2a). The protein putatively encoded by this ORF is highly similar to the *S. cerevisiae* Tfc1, one of the two DNA-binding subunits of the yeast transcription factor TFIIC. Part of the TFC1 promoter likely overlaps with the coding sequence of *YITPS1*. The relative position of these ORFs in *Y. lipolytica* is different from that found in other *Hemiascomycetes* in which TPS1 appears in a syntenic block that covers at least nine genes (Figure 2a). The sequence of the TPS1 promoter region of the widely used PO1a strain exhibited a GT deletion at −60 and a change C/T in position −314 relative to ATG with respect to the sequence that appears in *Gênolevures* [42].

**Disruption of the chromosomal copy of *YITPS1* does not affect growth in glucose**

Lack of growth in glucose of *S. cerevisiae* tps1 mutants has been attributed to loss of inhibition by T6P of hexokinase 2 [12] the glucose phosphorylating enzyme expressed during growth in this sugar [53,56]. Since T6P inhibition of *Y. lipolytica* hexokinase is the highest reported (K, 3.5 μM) [12,15] we studied the effect of the disruption of *TPS1* in this yeast. Attempts to disrupt *YITPS1* placing the disruption cassette after nucleotides 188 or 406 after the ATG failed, only when it was displaced to nucleotide 710 a correct disruption was obtained (Figure 2 b,c,d). We attribute the failures with the disruption cassettes located in the 5’ region of the coding sequence to interference with the expression of the neighbouring TFC1 gene (Figure 2a). Lack of TFC1 is lethal in *S. cerevisiae* [57] and in *Schizosaccharomyces pombe* [58] and this is likely to be the case also in *Y. lipolytica*. The *YITPS1* disruptants grew in glucose in contrast with the behavior of the *tps1* mutants of *S. cerevisiae*. The distinct phenotype could be caused by a difference in the glucose phosphorylating equipment between the two yeasts, by a lack of significant activity of Tps1 or both. We found that in glucose grown cultures of *Y. lipolytica* expression of the gene YAL10E15488 encoding a glucokinase (Flores and Gancedo, unpublished results) exceeded that of the gene encoding hexokinase (Figure 3). Also enzyme measurements showed that glucokinase constitutes the main phosphorylating activity in *Y. lipolytica* (Table 2). Since glucokinase is insensitive to inhibition by T6P [12,15], the growth in glucose of the *Yitps1* mutant may be explained by the scarce contribution of hexokinase to the glucose phosphorylating activity. Moreover, disruption of *YITPS1* slightly decreased the proportion of hexokinase activity (Table 2). Concentration of hexose mono or bis-phosphates and ATP were not affected with respect to that of a wild type during growth in glucose (Table 3) in contrast to what happens in a *S. cerevisiae* tps1 mutant which accumulates those compounds and loses ATP upon glucose addition. This result is consistent with a lack of control of the glycolytic flux by T6P in *Y. lipolytica*. The *YITPS1* disruptants showed a slightly shorter duplication time than the wild type (Wt 149±4 min, tps1 139±4 min, tps1/pCLF5 151±8 min, means of four experiments) (Figure S1). No immediate explanation can be provided for this difference.

**Levels of trehalose in *Y. lipolytica* are low but increase upon disruption of a gene encoding a putative trehalase or after heat shock**

Levels of trehalose in *Y. lipolytica* grown in glucose up to stationary phase or in glycogen were below 1 nmol/mg dry weight. A possible explanation for this result could be that the genes encoding the trehalose biosynthetic pathway enzymes were not expressed during growth in glucose, therefore we measured the expression of those genes in *Y. lipolytica*. In the *Gênolevures* database [42], YAL10D14476 is annotated as similar to *S. cerevisiae* TPS2 and YAL10E31086 shows the highest homology with *S. cerevisiae* TPS3/TSL1. All these genes were expressed during growth in glucose although the levels of *YITPS1* and *YITPS3* were low when compared to that of *YITPS1* (Figure 3). Although a western blot analysis of a fusion of Tps1 to the HA epitope indicated that the protein was expressed during growth in glucose (results not shown) its activity was very low (Table 4). This low activity could be an additional cause of the lack of effect of the *YITPS1* disruption on the growth in glucose. Expression of *YITPS1* under the control of the strong *YLETF1* promoter increased trehalose content and allowed detection of Tps1 activity which was almost undetectable in the wild type strain (Table 4). This result suggested that the low trehalose level was due to a low activity of the biosynthetic pathway. In addition to a low synthesis the low trehalose content could be due to the activity of a trehalase. We identified a gene, YAL10D15598, as the only sequence in the *Y. lipolytica* *Gênolevures* database [42] that shows homology with the trehalases (Figure 1). Phenotypic complementation of a *S. cerevisiae* tps1 mutant by expression of the *YITPS1* gene. The strains indicated were streaked on minimal medium with glucose or galactose as carbon sources and incubated at 30 °C for 4 days. Trehalose content of the strains cultured with glucose, except the mutant tps1 cultured in galactose, is given in the table (results of two independent cultures). The multicopy plasmid was pCLF1 and the centromeric one pCLF2.

doi:10.1371/journal.pone.0023695.g001

![Figure 1](image-url)
S. cerevisiae \textit{NTH1} or \textit{NTH2} genes encoding neutral trehalases. Measurements of \textit{YLNTH1} mRNA showed that it was expressed during growth in glucose (Figure 3). We disrupted \textit{YLNTH1} and measured an increased trehalose content in the resulting mutant. Such increase was dependent on the activity of Tps1 since in a double mutant \textit{nth1 tps1} no trehalose was detected (Table 4).

Heat shock increases trehalose in several yeasts [52,62]. In \textit{Y. lipolytica} a heat shock at 40°C for 2 h increased trehalose, although the final value varied depending on the strain (from 7 to 20 nmol/mg dry weight). This treatment was considered a strong one as this...
yeast does not grow at temperatures over 35°C. We measured the levels of mRNA corresponding to the genes related with trehalose metabolism after heat treatment (Figure 4). Levels of \( \text{YlTPS1} \) mRNA did not increase in spite of the presence of one CCCCT sequence in its promoter. Measurements of \( \beta \)-galactosidase produced from a fusion of the \( \text{YlTPS1} \) promoter to \( E. \text{coli lacZ} \) were consistent with this result (34 ± 3 mUnits/mg protein at time 0 vs 39 ± 4 mUnits/mg protein after 2 h, four independent experiments). Relative abundance of mRNAs corresponding to \( \text{YlTPS2} \) and \( \text{YlTPS3} \) increased 4 and 6 times respectively with the heat treatment. The higher increase of \( \text{YlTPS3} \) suggested an important role for this gene in the heat response. A disruption of \( \text{YlTPS3} \) abolished trehalose accumulation upon heat treatment raising the question that Tps3 could be another T6P synthase and hypothesis that cannot be ruled out due to the similarity between the \( \text{YlTPS1} \) and \( \text{YlTPS3} \) sequences. This possibility was made unlikely by the absence of trehalose in a \( \text{Yltps1} \) mutant after heat shock and by the lack of complementation of the glucose negative phenotype of a \( S. \text{cerevisiae} \) \( \text{tps1} \) mutant by the \( \text{YlTPS3} \) cDNA (Figure 5). We suggest that \( \text{YlTps3} \) is necessary to maintain the stability of the trehalose synthase complex during heat shock in \( Y. \text{lipolytica} \). This reveals a difference with \( S. \text{cerevisiae} \) where the absence of Tps3 does not affect trehalose content during heat shock [6].

Disruption of \( \text{YlTPS1} \) severely decreased growth at 35°C, only small colonies were visible after 7 days at this temperature (Figure 6). A plasmid carrying \( \text{YlTPS1} \) restored a wild type phenotype. The \( S. \text{cerevisiae} \) \( \text{TPS1} \) gene slightly improved growth of the \( \text{Yltps1} \) mutant at 35°C.

Treatment of \( Y. \text{lipolytica} \) at 4°C during 2 or 20 hours did not modify significantly the mRNA levels corresponding to the genes of the trehalose biosynthetic pathway (Figure 4), in contrast with the behavior of \( \text{TPS1} \) and \( \text{TPS2} \) in \( S. \text{cerevisiae} \) whose expression increase upon a treatment below 10°C [63].

In \( S. \text{cerevisiae} \) transcription factors Hsf1 and Msn2/4 are implicated in the response to heat shock and other stresses.

---

**Table 2. Phosphorylating activity on glucose and fructose and activities of hexokinase and glucokinase in \( Y. \text{lipolytica} \).**

| Strain and relevant genotype | Phosphorylating activity (mU/mg protein) | Specific activity (mU/mg protein) |
|-----------------------------|------------------------------------------|---------------------------------|
|                             | Glucose | Fructose | Hexokinase | Glucokinase |
| CJM 645 \( \text{YlTPS1} \) | 203 ± 20 | 68 ± 19 | 49 [24] | 154 [76] |
| CJM 651 \( \text{Yltps1} \) | 208 ± 15 | 47 ± 6 | 34 [16] | 174 [84] |

Strains were cultured in minimal medium glucose as indicated in Materials and Methods. Extracts and assay of phosphorylating activities were as described in Materials and Methods.

aHexokinase and glucokinase activities were calculated from the phosphorylation results with glucose and fructose using a Fructose/Glucose phosphorylation ratio of 1.4 for hexokinase ([92], our unpublished results). Figures in brackets indicate the percentage of the corresponding activity in the extract. Results are the mean values ± the standard deviations of four independent cultures.

---

**Figure 3. mRNA levels corresponding to genes encoding glucose phosphorylating enzymes and proteins related to trehalose metabolism in \( Y. \text{lipolytica} \).** Yeasts strains CJM 645, wild type, and CJM 651, \( \text{Yltps1}::\text{URA3} \), were grown in minimal medium glucose as indicated in Materials and Methods. mRNA levels were quantified by RT-qPCR as described in Materials and Methods. Three independent cultures were analyzed and three technical replicas were done for each run. Expression of each gene was normalized to that of the \( \text{YlARP4} \). The columns represent the mean values of the three biological experiments with bars indicating the standard deviation. The genes studied encode the following proteins: \( \text{GLK1} \), glucokinase; \( \text{HXK1} \), hexokinase; \( \text{TPS1} \), trehalose-6-P synthase; \( \text{TPS2} \), trehalose-6-P phosphatase; \( \text{TPS3} \), subunit of the trehalose synthase complex; \( \text{NTH1} \), neutral trehalase.

doi:10.1371/journal.pone.0023695.g003
Discussion

We have isolated and characterized the gene encoding trehalose-6-P synthase from the dimorphic yeast \( Y.\ lipolytica \). The identity of the gene is supported by the increase in trehalose and Tps activity in \( Y.\ lipolytica \) when the gene is expressed under the control of a strong promoter, the restoration of the growth in glucose and trehalose content to a \( S.\ cerevisiae \) \( tps1 \) mutant, and by sequence similarity to T6P synthases from other organisms. Although other sequences with high similarity to Tps1 could be identified in the \( Y.\ lipolytica \) Genolevures database [42] the only one active in trehalose synthesis when expressed in \( S.\ cerevisiae \) was \( YlTPS1 \).

Disruption of \( YlTPS1 \) impairs sporulation

When \( Y.\ lipolytica \) diploids homozygous for the \( tps1 \) mutation (CJM 724) were placed in sporulation conditions the sporulation frequency was reduced with respect to that of wild type (CJM 722) or heterozygous \( TPS1/tps1 \) (CJM 723) diploids. A similar behaviour in \( tps1/tps1 \) diploids in \( S.\ cerevisiae \) [67,68] was ascribed to a decreased expression of \( MCK1 \), a gene that stimulates expression of \( INE1 \) which encodes a transcriptional activator of sporulation [68]. Based on sequence homology we identified an ORF \( YALI0D20966 \) which exhibits 41% identity and 59% similarity with \( S.\ cerevisiae \) \( MCK1 \). We have measured the levels of mRNA corresponding to \( YALI0D20966 \) and to the genes implicated in trehalose metabolism both in a wild type diploid and in one homozygous for the \( tps1 \) mutation in sporulation conditions. After 8 days on sporulation medium the level of \( YALI0D20966 \) mRNA in a wild type was increased about 13 times while in a homozygous \( tps1/tps1 \) strain it reached a maximum of 3 fold (Figure 7). This behaviour parallels that of \( MCK1 \) in \( S.\ cerevisiae \) suggesting an implication of \( YALI0D20966 \) in sporulation in \( Y.\ lipolytica \). Levels of RNA corresponding to \( YlTPS1 \), \( YlTPS2 \), \( YlTPS3 \) or \( YlNTH1 \) did not vary significantly in either strain under the same conditions.

Table 3. Concentration of metabolites (mM) in a WT and Yltps1 strains during growth in glucose.

| Strains and relevant genotype | Glucose-6-P | Fructose-6-P | Fructose-1,6-P<sub>2</sub> | Trioses phosphate | ATP |
|------------------------------|-------------|--------------|----------------|------------------|-----|
| CJM 645 YlTPS1 | 0.18±0.06 | 0.04±0.01 | 0.33±0.02 | 0.08±0.02 | 0.47±0.10 |
| CJM 651 Yltps1 | 0.24±0.01 | 0.06±0.01 | 0.28±0.01 | 0.09±0.01 | 0.54±0.08 |

Yeast strains were cultivated in minimal medium glucose and sampled in exponential phase of growth. Metabolite extraction and quantification were done as described in Materials and Methods. Results are the mean values ± the standard deviations of three independent cultures.

doi:10.1371/journal.pone.0023695.t003

Table 4. Trehalose content and Tps1 activity in different strains of \( Y.\ lipolytica \).

| Strain and relevant genotype | Trehalose (nmol/mg dry weight) | Trehalose-6-P synthase (mU/mg protein) |
|------------------------------|-------------------------------|---------------------------------------|
| CJM 645 TPS1                 | <1                            | <5                                   |
| CJM 613 TPS1pCLF5            | 8.9±2.1                       | 55±5                                 |
| CJM 683 TPS1 nth1            | 18±2                          | n.d.                                 |
| CJM 703 nth1tps1            | <1                            | n.d.                                 |

Yeasts were grown in minimal medium glucose; trehalose and trehalose-6-P synthase were assayed as described in Materials and Methods. Results are the mean values ± the standard deviations of three independent cultures. n.d., not determined.

doi:10.1371/journal.pone.0023695.t004

[52,64,65]. In \( Y.\ lipolytica \) the protein Mby1 (YALI0B21582p) shows high similarity in its zinc finger domain to that of Msn2/4 and also binds STRE sequences [66]. A BLAST search of the \( Y.\ lipolytica \) database for genes encoding homologues of \( S.\ hof1 \) yielded gene YALI0E13948. Levels of mRNA corresponding to those genes increased about 3 times after heat shock (Figure 4) consistent with their possible implication in heat shock regulated processes.

Effects of \( TPS1 \) Disruption in \( Y.\ lipolytica \)
phosphorylating capacity of this yeast. A similar explanation might also apply for the phenotype described for a \textit{tps1} mutant of \textit{Hansenula polymorpha} \cite{14} a yeast in which glucokinase and hexokinase are present during growth in glucose \cite{77}. The levels of metabolites in the disrupted strain are in accordance with the lack of effect of the mutation on the growth in glucose. A slight increase in ATP concentration was measured in the \textit{Yltps1} mutant, a finding that parallels the results obtained for a \textit{tpsA} disruptant of \textit{A. nidulans} \cite{78}. With our current knowledge no clear explanation for these results can be advanced. Due to the “turbo design” of glycolysis \cite{13} a regulation of the initial steps of the pathway is necessary. In mammals glucose-6-phosphate controls hexokinase \cite{79} and in \textit{S. cerevisiae} T6P plays a similar role. Yeasts or fungi in which lack of T6P does not affect growth in glucose \cite{14,78} shall possess other mechanisms to regulate the first steps of glycolysis. It may be asked for the significance of the T6P inhibition of hexokinase in those organisms in which it appears not to play a significant role in the control of glycolysis. One possibility is that it may serve to control a yet unrecognized function of hexokinase, another one is that it is a consequence of the protein structure shared by most hexokinases and that organisms with a high glycolytic flux have taken advantage of it to control the first irreversible step of glucose metabolism. In \textit{Yarrowia lipolytica} differences in kinetic and regulatory properties of important glycolytic enzymes like phosphofructokinase \cite{23} or pyruvate kinase \cite{24} indicate that this yeast regulate glycolysis differently from \textit{S. cerevisiae}.

The decrease in sporulation observed in homozygous \textit{tps1} diploids parallels findings with \textit{tps1} mutants in other fungi like \textit{S. cerevisiae} \cite{67,68,80} Cryptococcus neoformans \cite{81} or Stagonospora nodorum \cite{82}. In \textit{S. cerevisiae}, the defect has been ascribed to a low expression of \textit{MCK1} an inducer of the gene \textit{IME1} whose expression triggers sporulation \cite{68}. The low level in \textit{Yltps1} diploids of mRNA corresponding to gene YALI0D20966 that appears to be the \textit{Y. lipolytica} homolog of \textit{ScMCK1} will suggest a similar mechanism for the decreased sporulation in this yeast and that the relationship between \textit{TPS1} and sporulation was already present in an ancient yeast like \textit{Y. lipolytica}.

**Figure 4. Levels of mRNA corresponding to genes \textit{YITPS1}, \textit{YITPS2}, \textit{YITPS3}, \textit{MHY1} (YALI0B21582) and \textit{HSF1} (YALI0E13948) during thermal stresses.** A sample of an exponentially growing culture of strain CJM 645 in minimal medium glucose (time zero) was taken before its transfer to 40°C or 4°C for 2 or 20 hours. mRNA levels were quantified by RT-qPCR as described in Materials and Methods. Two independent cultures were analyzed and three technical replicas were done for each run. Expression of each gene was normalized to that of \textit{YlARP4}. Values are shown relative to that of time zero. The columns represent the mean values of the experiments with bars indicating the standard deviation.

**Figure 5. Lack of complementation of \textit{Sctps1} by \textit{YITPS2}.** The \textit{S. cerevisiae} \textit{tps1} mutant (CJM 486) transformed with plasmids pCLF1 (\textit{YITPS1}), pCLF7 (\textit{YITPS3}) and pDB20 (void) were streaked on minimal medium with glucose or galactose and incubated at 30°C for 4 days.

doi:10.1371/journal.pone.0023695.g005

**Figure 6. Effect of \textit{YITPS1} disruption on growth at 35°C.** The strains were streaked on minimal medium glucose plates, incubated at the indicated temperatures and pictures taken 3 and 7 days after inoculation.

doi:10.1371/journal.pone.0023695.g006
Trehalose in *Y. lipolytica* in different conditions was below 1 nmol/mg dry weight. Disruption of a gene encoding a putative neutral trehalase or overexpression of *YlTPS1* increased trehalose content. A similar situation occurred in vascular plants in which trehalose was thought to be absent; incubation with validamycin A, an inhibitor of trehalase, showed the existence of the disaccharide [59,60]. Hydrolysis of trehalose by trehalase and a low level of Tps1 activity may be responsible for the low levels of the sugar in *Y. lipolytica*. It could be speculated that the main role of Tps1 is to provide T6P as an intermediate for pathways different from trehalose synthesis. Some bacteria produce biosurfactants or glycolipids that require T6P for their synthesis [83,84]. *Y. lipolytica* also produces biosurfactants even growing in aqueous media but their detailed structure is not known [85].

Heat shock increased the levels of trehalose and changed the levels of mRNA corresponding to *YlTPS2* and *YlTPS3* but not those of *YlTPS1*. A similar lack of response of *A. nidulans* tpsA has been described [78]. The increase of mRNA corresponding to *YlTPS3* as well as the absence of trehalose in the heat shocked Yltps1 mutant indicate an important role for the protein in the stability of the *YlTps3* complex in S. cerevisiae the complex consists of four proteins, Tps1, Tps2, Tsl1 and Tps3, only one sequence similar to that of Tps3/Tsl1 was found in the *Y. lipolytica* database. Decrease of trehalose levels during heat shock in *S. cerevisiae* requires the disruption of both Tsl1 and Tps3 [6]. In *S. cerevisiae* different mechanisms such as transcriptional activation of some genes, stabilization of certain RNAs [56] and activation of the trehalose synthase complex [87] contribute to trehalose accumulation by heat shock. Such detailed studies are not yet available for *Y. lipolytica*. Transcriptional response to heat shock in the case of the genes of the trehalose biosynthetic pathway in *S. cerevisiae* depends on repetitions of a CCCCT stretch (STRE sequence) in their promoters [63,87]. Function of STRE sequences in *S. cerevisiae* requires the Msn2/ Msn4 proteins [64]. The corresponding gene(s) is not known in *Y. lipolytica*. Hurtado and Rachubinsky [66] observed the high sequence homology of the Zn finger domain of Mhy1 with that of Msn2/4 and showed that this protein was able to bind to STRE sequences in vitro. These authors reported that the levels of *MHY1* mRNA were not increased after a heat shock at 35°C. Our results show that upon a heat shock at 40°C the levels of *MHY1* mRNA increase suggesting that *MHY1* may play a role in the regulatory response to this stress. It should be noticed that the high GC content in the *Y. lipolytica* DNA [89] may cause the presence of CCCCT sequences in the promoters of several genes that have not been related with responses to stress.

*Y. lipolytica* does not grow at temperatures over 35°C. The finding that disruption of *YlTPS1* impairs growth at this limit temperature suggests that trehalose plays a protective role against the changes produced under this condition [65].

Many evidences show that in different organisms the trehalose biosynthetic pathway, in addition to its primary role, has an influence in a variety of processes that range from growth on certain substrates or temperatures, to differences in virulence in pathogens. The targets of the pathway are different depending on the organism and even closely related yeast species like *C. neoformans* and *C. gattii* show important variations in the effects caused by perturbations of that pathway [89]. The finding that in *Y. lipolytica* that separated early in evolution from other yeasts [16], the trehalose biosynthetic pathway does not regulate glycolysis suggests that this regulatory property was acquired later along yeast evolution.

Supporting Information
