Transition metal-doped Sb₂Se₃ has become a heated topic caused by the strong nonlinear optical response and the ultrafast response time at high laser excitation. In this paper, the Co-doped Sb₂Se₃ with different doping amount (0.5, 1.0, and 1.5 W) nanofilms were prepared by magnetron sputtering technology, and the nonlinear behavior of Co-doped Sb₂Se₃ nanofilms at near infrared were systematically studied. The results of the femtosecond Z-Scan experiment indicate that the Co-doped Sb₂Se₃ nanofilms exhibit broadband nonlinear response properties owing to the free carrier absorption, the Kerr refraction, the two-photon absorption, and the free carrier refraction. The nonlinear absorption coefficients of Co-doped Sb₂Se₃ nanofilms are from 3.0 × 10⁻⁹ to 2.03 × 10⁻⁸ m/ W under excitation at 800, 980, and 1,030 nm, and the nonlinear refractive index of the Co-doped Sb₂Se₃ nanofilms is from 4.0 × 10⁻¹⁶ to -3.89 × 10⁻¹⁵ m²/ W at 800, 980, and 1,030 nm. More importantly, Co-doped Sb₂Se₃ (1.5 W) nanofilm exhibits ultrafast carrier absorption (< 1 ps) and a stronger transient absorption intensity of ΔOD > 6.3. The Co-doping content can controllably tune the crystalline degree, the ultrafast carrier absorption, the intensity of the reverse saturation absorption, the broadband nonlinear optical response, and the carrier relaxation time of Co-doped Sb₂Se₃ nanofilms. These results are sufficient to support their applications in broadband nonlinear photonic devices.

Keywords: Co-doped Sb₂Se₃ nanofilms, ultrafast broadband response, near-infrared, ultrafast carrier absorption, reverse saturation absorption

INTRODUCTION

The special interactions between light and matter in selenide materials are ideal applications for interferometers, electrocatalysis, ultrathin transistors, sensors, and optoelectronic devices (Radisavljevic and Kis, 2013; Medina et al., 2017; Ai et al., 2018; Jiang et al., 2019). In nonlinear optics, the selenides, due to their unique reverse saturation absorption (RSA), which decreases transmittance with the incident laser increase, have attracted much attention (Wang et al., 2012; Lin et al., 2013). The RSA behavior occurs because the absorption cross-section of the excited state in the substance is larger than the ground state, which leads to the ground state absorption being less than that of the excited state (Henari and Dakhel, 2011; Tuhl et al., 2012). The RSA properties of selenides can be widely used in optical information, nonlinear optoelectronic components, optical sensing, and integrated optics (Djordjevic and Arabaci, 2010; Volz et al., 2012; Jia et al., 2018). For example, WSe₂ in selenides exhibits RSA and optical limiting properties that can be applied to nonlinear...
optoelectronic components (Major et al., 2004; Andreev et al., 2011). However, the selenides with RSA properties still face the solution of the ultrafast broadband nonlinear optical response, higher carrier absorption intensity, long carrier relaxation time, and other problems.

In past decades, researchers have focused on Sb$_2$Se$_3$ (V–VI group), which is widely used in optical devices due to its excellent optical nonlinear properties (Molli et al., 2016; Liu et al., 2019). To further improve the photoelectric properties of Sb$_2$Se$_3$, the group IV, VII, and VI elements are frequently doped on Sb$_2$Se$_3$ (Choi et al., 2006; Lee et al., 2019; Ren et al., 2020). A variety of metal elements have been selected for doping with Sb$_2$Se$_3$ due to their excellent photoelectric properties (Cao et al., 2014; Ning et al., 2021). In many metal elements, Co was selected to dope the Sb$_2$Se$_3$ because it can effectively capture the photogenerated carrier and promote free-carrier absorption (FCA) at near infrared. The success of Co doping can effectively adjust the optical bandgap and accelerate the FCA and two-photon absorption (TPA) of Sb$_2$Se$_3$, making the nonlinear response transfer to the broadband. It is of great significance for the selection of a greater metal dopant to doped Sb$_2$Se$_3$ for nonlinear optical devices and electronic devices due to understanding the doping effect and nonlinear properties of Co-doped Sb$_2$Se$_3$.

In this paper, the pure and Co-doped Sb$_2$Se$_3$ nanofilms with different contents of Co dopant (0.5, 1.0, and 1.5 W) nanofilms were successfully prepared by using magnetron sputtering technology. The Co-doped Sb$_2$Se$_3$ (1.5 W) nanofilm exhibits an excellent ultrafast broadband nonlinear response at the near infrared, higher nonlinear absorption coefficients, higher transient absorption intensity, ultrafast carrier absorption, and high linear transmittance. By the precise control of magnetron sputtering conditions (such as the temperature, deposition time of the nanofilms, radio frequency, and direct current power), smooth and uniform Co-doped Sb$_2$Se$_3$ nanofilms were successfully prepared. The results of the transient absorption experiment suggest that the ultrafast broadband nonlinear optical response of Co-doped Sb$_2$Se$_3$ nanofilms is caused by FCA and TPA, and the special nonlinear optical properties in Co-doped Sb$_2$Se$_3$ nanofilms depend on the amount of Co dopant. We also obtained the close-aperture (CA) Z-scan signals of the Co-doped Sb$_2$Se$_3$ nanofilms by the CA Z-scan experiment. The composition of nonlinear refraction of the Co-doped Sb$_2$Se$_3$ nanofilms can be attributed to the free carrier refraction (FCR) and Kerr refraction. In addition, the Co-doped Sb$_2$Se$_3$ nanofilms also exhibit ultrafast carrier absorption, higher transient absorption intensity, and longer carrier relaxation time. It has a new reference value for the preparation of near-infrared broadband photonic devices.

**EXPERIMENT**

**Materials**
The magnetron sputtering target of Sb$_2$Se$_3$, with a purity of 99.99%, a diameter of 6.0 cm, and a purity of 99.999% was purchased from Beijing JHCC Vacuum Equipment Co., Ltd. The sputtering target of Co with a thickness of 0.5 cm, a diameter of 6.0 cm, and a purity of 99.999% was purchased from Beijing JHCC Vacuum Equipment Co., Ltd.

**Sample Preparation**
The pure Sb$_2$Se$_3$ and Co-doped Sb$_2$Se$_3$ nanofilms were prepared by using magnetron sputtering technology. The sapphire substrate was washed by anhydrous ethanol, deionized water, and acetone for 30 min until the substrate was clean completely and dried at room temperature. Figure 1 shows the diagram of the process of the Co-doped Sb$_2$Se$_3$ nanofilms. To obtain the best thickness uniformity of the film, the distance between the target and the substrate was fixed at 10.2 cm. The sputtering power of the radio frequency target in the deposition process was 50 W, and the sputtering powers of the direct current target were 0.5, 1.0, and 1.5 W. The vacuum of the sputtering room was 4.5 × 10$^{-3}$ Pa, the sputtering pressure was 3.0 Pa, Argon was employed as a working gas with a gas flow rate of 20 sccm, the substrate temperature was set to 150°C, and the sputtering time was 1 h to prepare the pure and Co-doped Sb$_2$Se$_3$ nanofilms.

**Instruments**
The morphology and thickness of pure and Co-doped Sb$_2$Se$_3$ nanofilms were obtained by field-scanning electron microscope (SU70, Hitachi, Japan), the X-ray diffraction analysis of pure and Co-doped Sb$_2$Se$_3$ nanofilms was carried out by using an X-ray diffractometer (XRD; D8, Bruker, Germany). The elemental analysis of Co-doped Sb$_2$Se$_3$ nanofilms was tested by energy dispersive spectroscopy (EDS; XM260S, AmetekGenesis, United States). The transmittance and linear absorption spectra of the pure and Co-doped Sb$_2$Se$_3$ nanofilms were characterized by the spectrophotometer (Uv-Vis; Uv-3600i PLUS, SHIMADZU, Japan).

In the transient absorption experiment, by changing the optical path difference between the detecting and pumping light, a variation of the white supercontinuum spectrum with different delay times can be obtained. Thus, the frequency-doubled...
Yb:KGW laser was selected for the transient absorption experiment, and the laser can provide 190 femtosecond (fs) laser pulses at 450 nm. In the fs transient absorption experiment, the repetition rate, probe pulses, and specific pump fluence were set at 137 Hz, 800–1,050 nm, and 82 μJ/cm², respectively (Fang et al., 2015; Fang et al., 2016). The nonlinear optical characteristics of the pure and Co-doped Sb₂Se₃ nanofilms were tested by fs Z-Scan experiments. The light source used an optical parameter amplifier (OPA, Light Conversion ORPHEUS), which was pumped by a mode-locked Yb:KGW fiber laser. The measurement parameters were set at 190 fs pulse and 20 Hz, and the waist radius of the laser was 33 μm. The energies of the laser excitation were set at 300, 400, and 500 nJ, respectively.

RESULTS AND DISCUSSION

Structural and Compositional Analysis

Figure 2 shows the XRD patterns of the Sb₂Se₃ and the Co-doped Sb₂Se₃ nanofilms. It can be seen from the XRD patterns that Co-doped Sb₂Se₃ nanofilms were successfully prepared and exhibited a polycrystalline structure. According to the XRD pattern, compared with the Sb₂Se₃ nanofilm (PDF#15-0816) (Zhou et al., 2015; Liu et al., 2019), the diffraction characteristic peak (310) of Co-doped Sb₂Se₃ nanofilms increased, and the lattice spacing of the (310) is 3.669 nm. In addition, the diffraction characteristic peaks of the Co-doped Sb₂Se₃ nanofilms exhibit an increasing trend with the increase of Co dopant. It can be clearly seen from the XRD patterns that the diffraction characteristic peaks of the Co-doped Sb₂Se₃ nanofilms are located at 24.575 (0.5 W), 24.441 (1.0 W), and 24.296 (1.5 W), respectively, which are all offset compared with the diffraction characteristic peaks of the pure Sb₂Se₃ nanofilm (24.987). In addition, the lattice constants of the Co-doped Sb₂Se₃ nanofilms are also calculated as 11.839 (0.5 W), 11.853 (1 W), and 11.891 (1.5 W), respectively, which are all smaller than the lattice constant of pure Sb₂Se₃ (11.902). In past reports, Co dopants in the Sb₂Se₃ system can be used as a substitute site of Sb or Se as well as interstitial atoms (Li et al., 2016; Mahani and El-Sayad, 2019). Under the premise that Se and Sb are abundant enough, Co can effectively replace Sb to form the most favorable structure. If the Sb position in Sb₂Se₃ is successfully replaced by some dopant, the homologous diffraction characteristic peaks are shifted and exhibited in the XRD pattern. The shift of the characteristic diffraction peaks was observed in the Co-doped Sb₂Se₃ nanofilms, confirming that the Co doping is at the grain boundary of Sb₂Se₃ rather than entering its lattice and that the Co dopant may also enter the substitution site of Sb. The supercell of Co-doped Sb₂Se₃ was shown in Figure 3.

The elemental composition of the Co-doped Sb₂Se₃ nanofilms was detected by EDS. The results of the EDS show that, with the increase of DC sputtering power in the Co target, the Co content of the Co-doped Sb₂Se₃ nanofilms increases, but the peak positions of the Se and Sb in the film have not shifted, and the content of Co in the Co-doped Sb₂Se₃ nanofilms was 0.63% (0.5 W), 1.61% (1.0 W), and 3.35% (1.5 W), respectively. The results of the EDS provide strong evidence for Co successfully doping at grain boundaries of Sb₂Se₃. Although the Co doping amount increases, the resistance of the Sb₂Se₃ grain boundary gradually decreases, which leads to the formation of a space charge region near the grain boundary.

Morphological and Optical Analysis

To study the morphology and thickness of pure and Co-doped Sb₂Se₃ nanofilms, the nanofilms were characterized by SEM, and the results are shown in Figure 4. The nanofilms that were prepared by magnetron sputtering are smooth uniform and free of cracks. In addition, we also characterize the thickness
of the pure and Co-doped Sb$_2$Se$_3$ nanofilms. The thicknesses of the pure and Co-doped Sb$_2$Se$_3$ nanofilms are both 150 nm. According to previous reports (Cattaruzza et al., 2009; Wu et al., 2015; Hymavathi et al., 2017), the morphology of doped films is determined by the deposition conditions, particularly the power of direct current magnetron sputtering. In accordance with the result of the elemental mapping (Figure 4(f ~ h)), the elements of Sb, Se, and Co are uniformly dispersed in the entire Co-doped Sb$_2$Se$_3$ nanofilms.

Figure 5 shows that the transmittance and absorption spectrum of pure and Co-doped Sb$_2$Se$_3$ nanofilms were obtained by spectrophotometer. The linear absorption edge of the optical bandwidths of the pure and Co-doped Sb$_2$Se$_3$ nanofilms at near infrared can be found. Compared with the pure Sb$_2$Se$_3$ nanofilms, the red shift of the linear absorption edge of the Co-doped Sb$_2$Se$_3$ nanofilms can be attributed to the different ionic radius of Co than that of Sb, which changes the bond length with Se at replacement Sb, thus leading to a change in
the eigenfrequency. The change of the eigenfrequency moves the linear absorption edge of the Co-doped Sb$_2$Se$_3$ nanofilms and, hence, the red shift (Tian and Liu, 2006). Furthermore, the increase in Co dopant content leads to increasing the deficiency, which leads to an increase in the average atomic distance, thus leading to a decrease in the energy level spacing. For linear absorption, we have Tacu’s formulation, which is given as follows (Filipchenko and Naurizbaev, 1976):

\[
\alpha = \frac{A}{h\nu}(\nu - E_g)^n
\]

where the coefficient of linear absorption is denoted by \(\alpha\), \(A\) represents a constant, \(E_g\) represents the optical band gap, \(n\) represents an index (\(n = 1, 2, 3\)), and the incident photon energy is denoted by \(\nu\). The optical band gap (\(E_g\)) values of the pure and Co-doped Sb$_2$Se$_3$ nanofilms (0.5, 1.0, and 1.5 W) are, respectively, calculated as 1.93, 1.83, 1.80, and 1.77 eV. Figures 5C, D exhibit the transmission spectrum of the pure and Co-doped Sb$_2$Se$_3$ nanofilms. It can be clearly seen that the A and B thin films both exhibit more than 80% transmission in the range of 800–1,100 nm, and the dopant of Co has no effect on the transmittance at near infrared.

Nonlinear Optical Properties

The nonlinear signals of the pure and Co-doped Sb$_2$Se$_3$ nanofilms, which were obtained by fs Z-scan experiment at 800, 980, and 1,030 nm, are used to understand the mechanism of the nonlinear response and regulation. The open-aperture (OA) Z-scan results of the pure and Co-doped Sb$_2$Se$_3$ nanofilms are shown in Figure 6(a–c). For the pure and Co-doped Sb$_2$Se$_3$ nanofilms, the RSA phenomenon was observed at 800 nm, and no signals were obtained at 980 and 1,030 nm for...
the pure Sb$_2$Se$_3$ nanofilm. Through the linear absorption spectroscopy of the pure and Co-doped Sb$_2$Se$_3$ nanofilms, it can be seen that the $E_g$ of the pure and Co-doped Sb$_2$Se$_3$ nanofilms are greater than $h\nu$ but less than $2h\nu$, which indicates that the pure and Co-doped Sb$_2$Se$_3$ nanofilms both exhibit a TPA. For the Co-doped Sb$_2$Se$_3$ nanofilms, the OA Z-scan signals were exhibited at 980 and 1,030 nm, and it also shows that, with the increase of the doping concentration, the amplitude of the OA Z-scan signals exhibited the corresponding increase. In addition, we also obtained the OA Z-scan signals of the pure and Co-doped Sb$_2$Se$_3$ nanofilms (1.5 W) under different excitation energy at
800 nm. For the pure Sb\textsubscript{2}Se\textsubscript{3} nanofilm, with the increase of the excitation energy, the OA Z-scan signals did not change; therefore, it can be inferred that the pure Sb\textsubscript{2}Se\textsubscript{3} is a pure third-order nonlinear effect, and the OA Z-scan signal amplitude of the Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms (1.5 W) increased with the increase of the excitation energy. Therefore, we infer that the Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms have a higher-order nonlinear absorption phenomenon, that is, FCA. For the higher-order nonlinear absorption phenomenon, we have (Lakhwani et al., 2010)

![Image of graphs showing normalized transmittance against Z (mm) for different excitation energies and wavelengths.](image-url)
Here, $\alpha$ represents the global absorption coefficient, $\gamma$ stands for the fifth-order nonlinear absorption coefficient, $T(z)$ stands for the normalized transmittance, $\beta$ represents the third nonlinear absorption coefficient of the thin films, and $I_0$ stands for the light intensity at the focus. The effective thickness of the nanofilms is denoted by $L_{\text{eff}}$, and $L_{\text{eff}} = 1 - e^{-\alpha_0 L}/\alpha_0$, where $\alpha_0$ is the linear absorption coefficient of the thin film, $L$ represents the thickness of the samples, $z$ is the distance between the sample and the focal point, and $z_0$ is the derived length of the beam. The $\beta$ and the $\gamma$ of the pure and Co-doped Sb$_2$Se$_3$ nanofilms are exhibited in Table 1.

The calculated results show that, with the increase of excitation energy, the values of $\beta$ and $\gamma$ of the Co-doped Sb$_2$Se$_3$ nanofilms increase correspondingly, thus confirming that there is FCA in the Co-doped Sb$_2$Se$_3$ nanofilms. As is known to all, the interaction between matter and light can be effectively increased by Co nanoparticles, which can also illustrate the high carrier mobility (Han et al., 2006; Ahlam et al., 2012). In addition, Co nanoparticles can effectively capture photogenerated carriers and can also inhibit the combination of carriers and holes in the local electric field (Li et al., 2017; Nasir et al., 2017). The formation of the space charge region formed by the Co dopant leads to a larger electron base, so the probability of transition becomes larger during the absorption of photon energy and the increase of the Co dopant content can provide more free carriers; thus, the increment of the free carriers leads to the enhancement of the nonlinear effect.

Owing to the increase of excited state absorption and high carrier mobility brought by Co nanoparticles, FCA and TPA are successfully set up in the Co-doped Sb$_2$Se$_3$ nanofilms with the successful doping of Co into Sb$_2$Se$_3$. Therefore, the RSA behavior of the Co-doped Sb$_2$Se$_3$ nanofilms was observed at 980 and 1,030 nm. As the content of the Co dopant increases, the intensity of RSA behavior exhibits a corresponding increase. This phenomenon is because the increase of the content of Co dopant can provide more Co nanoparticles, thus providing more free carriers, which can further promote faster and stronger absorption in the excited state.

![Figure 8](A) The results of the transient absorption experiment of the pure Sb$_2$Se$_3$ nanofilm at near infrared. (C–D) The results of the transient absorption experiment of Co-doped Sb$_2$Se$_3$ (0.5, 1, and 1.5 W) nanofilms at near infrared.
The CA Z-scan signals (800, 980, and 1,030 nm) of the pure and Co-doped Sb$_2$Se$_3$ nanofilms were obtained by using the CA fs Z-scan experiment as shown in Figure 7. For the pure Sb$_2$Se$_3$ nanofilm, the CA Z-scan signal was observed at 800 nm, which can be attributed to Kerr refraction caused by the nonlinear systematic dispersion of bound electrons appearing near the intrinsic absorption edge although there was no CA Z-scan signal observed at 980 and 1,030 nm, and it can be caused by the weak Kerr refraction. For the Co-doped Sb$_2$Se$_3$ nanofilms, the CA Z-scan signals were observed at 800, 980, and 1,030 nm, which indicates the existence of high-order nonlinear refraction (FCR). In addition, with the increase of the Co dopant content, the amplitude of the CA Z-scan signals increased correspondingly. According to the results of the OA Z-scan signals of the Co-doped Sb$_2$Se$_3$ nanofilms, with the increase of the Co dopant content, more Co nanoparticles can be provided, which led to the increase of photogenerated carriers. Therefore, it can be concluded that the content of photogenerated carriers in the Co-doped Sb$_2$Se$_3$ nanofilms is relatively high, and the excess carriers can participate in the refraction of free carriers. Thus, it can be concluded that there are FCR at 980 and 1,030 nm, and the FCR is dominant. According to the plasma dispersion effect of carriers, the refraction effect of free carriers increases with the increase of incident wavelength (Soref and Bennett, 1987; Gao et al., 2005). Therefore, the Co-doped Sb$_2$Se$_3$ nanofilms exhibit a self-defocusing behavior at 980 and 1,030 nm, which are constructed by the FCR and Kerr refraction. In addition, we also obtained the CA Z-scan signals of the Co-doped Sb$_2$Se$_3$ nanofilm (1.5 W) and pure Sb$_2$Se$_3$ nanofilm, which were excited under different excitation energy at 800 nm as shown in Figure 7D. For the pure Sb$_2$Se$_3$ nanofilm, there was no change in CA

![Graphical representations of CA Z-scan signals for pure and Co-doped Sb$_2$Se$_3$ nanofilms at different excitation energies and wavelengths.](image_url)
For the Co-doped Sb$_2$Se$_3$ nanofilm (1.5 W), the signals of the CA Z-scan indicate that the amplitude of the nonlinear signal increases with the increase of the excitation energy. The reason for the phenomenon is that, with the increase of the excitation energy, excess carriers, which can participate in the refraction of the free carriers, are generated, thus leading to the enhancement of the refraction of the free carriers (Fang et al., 2013). For nonlinear refraction, we assume that the incident laser has a Gaussian distribution, and then the sample transmittance on the far-field axis is proportional to the phase shift (Gao et al., 2005).

\[
\Delta \Phi = \frac{2\pi}{\lambda} L_{\text{eff}} n_2 I_0
\]  

(4)

The effective thickness of the samples is denoted by $L_{\text{eff}}$ and $L_{\text{eff}} = 1 - e^{-\alpha_0 L}$, where $n_2$ represents the nonlinear refractive index, $L$ stands for the thickness of the samples, $I_0$ represents the light intensity at the focus, $\lambda$ stands for the excitation wavelength, and $\alpha_0$ represents the linear absorption coefficient of the thin film. For the Kerr system, the peak intensity of the incident laser and the nonlinear refractive index have the same radial profile. The interpolation formulas for the normalized peak-valley transmittance ($\Delta T_{p-v}$) and peak-valley separation in z ($\Delta Z_{p-v}$) are shown in Eqs 5, 6; (Gao et al., 2005).

\[
\Delta T_{p-v} = 0.406\Delta \Phi
\]

(5)

\[
\Delta Z_{p-v} = 1.7\ell_0
\]

(6)

The values of $n_2$ can be calculated by using Eqs 4–6 and are shown in Table 2.

### Transient Absorption Analysis

The nonlinear optical properties of pure and Co-doped Sb$_2$Se$_3$ nanofilms were studied by transient absorption experiment. To ensure the excitation efficiency, the pumping light was set at 450 nm. The change of absorption intensity at a specific wavelength can be represented as the variation of the optical density ($\Delta OD$), which is obtained by transient absorption spectroscopy. For the transient absorption experiment, $\Delta OD$ can be calculated as (Li et al., 2014)

\[
\Delta OD(\lambda_p, t) = -\log_{10}\left(\frac{T_{on}}{T_{off}}\right)
\]

(7)

where $\lambda_p$ represents the wavelength of probing light, $T_{on}$ represents the light of the probe, $t$ stands for the delay time and the total transmittance of pumping, and the transmittance of probing light is denoted by $T_{off}$.

For the pure Sb$_2$Se$_3$ nanofilms, the RSA phenomenon was observed at 780–830 nm ($\Delta OD>0$), but no nonlinear signal was detected in other probe regions (Figures 8A,B), which is in synchrony with the result of the fs Z-scan signal of the pure Sb$_2$Se$_3$ nanofilms. According to the results of linear absorption of the pure Sb$_2$Se$_3$ nanofilm, TPA occurs when the optical bandgap ($E_g$) is greater than $h\nu$ and less than 2$h\nu$. With the successful doping of Co into Sb$_2$Se$_3$, TPA and FCA are successfully established in the Co-doped Sb$_2$Se$_3$ nanofilms, which is due to the increase of carrier mobility and excited-state absorption brought by Co nanoparticles. Co-doped Sb$_2$Se$_3$ nanofilms exhibit the RSA phenomenon with high transient absorption ($\Delta OD > 6.5$), broadband nonlinear response (800–1,030 nm), and ultrastable carrier absorption (<1 picoseconds) at near infrared at Figures 8C,D compared with Sb$_2$Se$_3$ nanofilms.

Although the content of Co dopant increases, the carrier absorption rate and intensity of RSA of the Co-doped Sb$_2$Se$_3$ nanofilms exhibit a corresponding increase. In addition, the increase in the doping amount of Co can provide more Co nanoparticles, which can further promote the absorption of the excited state faster and stronger. When the DC sputtering power was increased to 1.5 W, the Co-doped Sb$_2$Se$_3$ nanofilm exhibited the strongest transient absorption ($\Delta OD > 15$) and...
ultrafast carrier absorption (<1 picoseconds) as shown in Figure 8D. Through the analysis of the transient spectrum, it can be seen that the transient absorption intensity of all Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanoﬁlms is 800 < 980 < 1,030 nm; according to the plasma dispersion effect of carriers, the absorption and refraction effects of free carriers increase with the increase of incident wavelength. It is further conﬁrmed that FCA and FCR play a dominant role in the nonlinear response at 980 and 1,030 nm. In all the transient absorption spectra, it can be found that the signal has no obvious movement during the whole delay time, which suggests that the TPA and FCA may be from the uniform energy level during the whole delay time (He et al., 2010). In addition, the sapphire substrate has no influence on the transient absorption experiment of the Co-doped and pure Sb\textsubscript{2}Se\textsubscript{3} nanofilms. Moreover, the differences between Co-doped and pure Sb\textsubscript{2}Se\textsubscript{3} nanofilms were measured by the Gaussian beam focal plane, which proves that the Co-doped and pure Sb\textsubscript{2}Se\textsubscript{3} nanofilms do not suffer optical damage in the transient absorption experiment. Figure 10 exhibits the schematic diagram of the energy levels of the Co-doped and pure Sb\textsubscript{2}Se\textsubscript{3} nanofilms, one-photon absorption, and FCR.

Figure 9 shows the transient absorption ﬁtting curves of pure and Co-doped Sb\textsubscript{2}Se\textsubscript{3} (0.5, 1, and 1.5 W) nanofilms at different time scales under 450 nm laser excitation. For the pure and Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms, there was no inﬂuence between the pump light and the carrier relaxation, which proves that the transient absorption experiment was carried out under steady conditions. Multiple exponential functions are selected to ﬁt the transient absorption curve of the pure and Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms, and the formula is as follows (Fang et al., 2017):

$$\frac{\Delta T}{T} = C_1 \exp(-t/\tau_1) + C_2 \exp(-t/\tau_2)$$

(8)

$$\frac{\Delta T}{T} = C_1 \exp(-t/\tau_1) + C_2 \exp(-t/\tau_2) + C_3 \exp(-t/\tau_3)$$

(9)

where \(C_1, C_2, \) and \(C_3\) represent the amplitudes of the third, second, and ﬁrst components, respectively. For the pure Sb\textsubscript{2}Se\textsubscript{3} nanofilm, which was excited by 450 nm, the carrier relaxation time values (\(\tau_1 \) and \(\tau_2\)) were calculated as 1.74 ± 0.74 ps and 3.89 ± 0.73 ns. The values of transient absorption (\(\tau_1, \tau_2, \) and \(\tau_3\)) of the Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms under the same laser excitation were calculated as 1.58 ± 0.9 ps, 12.39 ± 0.21 ps, and 4.42 ± 0.82 ns (0.5 W); 1.32 ± 0.49 ps, 13.35 ± 0.4 ps, and 4.63 ± 0.81 ns (1.0 W); and 1.73 ± 0.99 ps, 12.03 ± 0.26 ps, and 4.89 ± 0.79 ns (1.5 W), respectively. The calculated results show that the doping amount of Co can adjust the carrier relaxation time of the Sb\textsubscript{2}Se\textsubscript{3} nanofilms. In addition, the results also conﬁrm that Co nanoparticles can effectively inhibit the composite process of carrier and hole, thus improving the FCA efﬁciency. The carrier relaxation processes for the pure and Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms are shown in Figure 10. In the whole relaxation process of pure and Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms, the different relaxation mechanisms determine the relaxation time of carriers at different steps. For the pure Sb\textsubscript{2}Se\textsubscript{3} nanofilms, the \(\tau_1\) is caused by the cooling of thermal carriers, and the \(\tau_2\) is caused by the relaxation of nonradiative transition of carriers in the optical bandgap. Although for the Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms, \(\tau_3\) is caused by the relaxation of nonradiative transition of carriers from CB to VB, the \(\tau_3\) is caused by the relaxation of nonradiative transition of carriers from CB to doping level, and the \(\tau_1\) is caused by the electron-phonon scattering.

CONCLUSION

In conclusion, this study conﬁrms that the enhancement of excited state absorption at near infrared caused by FCA, FCR, TPA, and Kerr refraction is the main mechanism of the broadband nonlinear response of Co-doped Sb\textsubscript{2}Se\textsubscript{3} ﬁlms, which were prepared by magnetron sputtering. Compared with the pure Sb\textsubscript{2}Se\textsubscript{3} nanofilm, the Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms exhibit the following superior nonlinear optical properties. (I) Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms exhibit ultrafast carrier absorption (ps) at near infrared and excellent broadband nonlinear response (800–1,030 nm). (II) High nonlinear absorption coefﬁcients, high nonlinear refraction index, long carrier relaxation time, and the ultrafast carrier absorption of Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms are determined by the content of the Co dopant. (III) The transient absorption intensity of Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms (1.5 W) is achieved \(\Delta OD>15\). Finally, the Co-doped Sb\textsubscript{2}Se\textsubscript{3} nanofilms provide more reference value for selecting more suitable elements as the dopants of Sb\textsubscript{2}Se\textsubscript{3} to prepare the broadband nonlinear optical devices.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/supplementary material, further inquiries can be directed to the corresponding author.

AUTHOR CONTRIBUTIONS

DS contributed to conception and design of the study. WHS organized the database. DS wrote the ﬁrst draft of the manuscript. YF, WUS, QM, and XY contributed to manuscript revision, read, and approved the submitted version.
