INTRODUCTION

Beef allergy is a rare food allergy in both children and adults. Studies regarding this particular allergy have demonstrated a predilection toward atopic dermatitis among children. A previous report described 10 cases of food allergy caused by beef in adults, presenting various clinical manifestations, including urticaria, angioedema, anaphylaxis and gastrointestinal symptoms. Although the skin prick test and serum specific IgE to beef, pork and milk allergens showed negative results using commercial kits, the BAT showed significant upregulation of CD203c in a dose-dependent manner compared to both non-atopic and atopic controls. To our knowledge, this is the first case study of beef allergy consisting of a non-IgE-mediated reaction. The detection of food allergies using direct basophil activation is suggested to complement conventional diagnostic tests.

Key Words: Beef allergy; basophil activation test; CD203c, human

CASE REPORT

A 37-year-old woman was referred to our allergy clinic for generalized urticaria, nausea, abdominal pain and hypotension one hour after consuming a bowl of beef soup. Prior to this episode, she had experienced generalized urticaria and abdominal discomfort several times after eating grilled beef and pork, which had been treated with intravenous steroids and antihistamine at local emergency centers. She had been able to consume milk, chicken, eggs and fish without any difficulties for three years. She was also atopic with positive responses to house dust mites, tree and weed pollens, based on the skin prick test, and was previously diagnosed with allergic rhinitis. To exclude the possibility of food additive hypersensitivity, oral challenge tests with sulfite (200 mg) and sodium benzoate (400 mg) were performed and the results were negative. The results of the skin prick test conducted with a panel of commercial food reagents (Bencard Co., Brentford, UK), homemade raw extracts of beef, pork, milk and bovine serum albumin (New England Biolabs, Hitchin, Hertfordshire, UK) were negative against all allergens tested. Serum specific IgE antibodies to beef, pork and milk allergens measured by the ImmunoCAP system (Phadia, Uppsala, Sweden) showed negative results (<0.35 KU/L). To confirm basophil activation status, flow cytometric analysis (FACScantoII; BD Immunocytometry Systems, San Jose, CA, USA) for activated basophils was performed using allophycocyanin (APC)-conjugated anti-HLA-DR, fluorescein isothiocyanate (FITC)-conjugated anti-CD123 and phycoerythrin-conju-
Beef allergy has been considered a rare food allergy and the pathogenic mechanism has been unknown. Previous studies suggested an IgE-mediated reaction as the pathogenic mechanism in beef allergy and have identified several causative proteins as major allergens, including Bos d 6, Bos d 7, Gal d 5, and α-gal. However, there are common discrepancies among these studies with regard to their clinical histories, results from skin prick tests and serum specific IgE. A double-blind, placebo-controlled food challenge was advocated as the gold standard for diagnosing food allergies may complement conventional tests.

Basophils can be activated by a number of stimuli, which are mediated by the high-affinity IgE receptor (FcERI) or distinct activation pathways, such as the complement system or pharmacological agents. BAT has been used to diagnose pollen-associated food allergies, egg allergies and peanut allergies, suggesting that it is an effective tool for food allergy diagnosis. In the present case study, BAT results were relevant to the clinical history of the patient, showing upregulation of CD203c from 20.4% to 56.9% following incubation with 1 mg/mL of beef extract.

CD203c has recently been evaluated as a marker of basophil activation. In comparison with CD63, CD203c was expressed only in basophils, suggesting that no additional marker is required to monitor basophil activation. Moreover, the detection of CD203c expression does not require preincubation with interleukin-3 (IL-3) and the anti-IgE antibody conjugate. The upregulation of CD203c is not restricted to FcERI-induced signalling but, rather, is mediated by other signalling pathways, such as IL-3 or tetradecanoyl phorbol acetate (TPA), which is a stimulator of the protein kinase C (PKC) pathway.

A previous study documented the extremely rapid TPA-mediated upregulation of CD203c and increase in PKC activity in the colonic mucosa after consumption of beef. Therefore, the symptoms in the present case could have been due to a non-IgE-mediated reaction with direct basophil activation due to the beef allergy.

In conclusion, using BAT, we confirmed a mechanism of beef-induced non-IgE-mediated anaphylaxis in a patient.
