INTRODUCTION
Since medieval times, plants have been the major source of medicines for the treatment of various diseases. At present, plants remain an integral part of the healthcare in different countries including developed countries. According to the World Health Organization (WHO), 80% of the people living in rural areas depend on the medicinal plants as primary healthcare system [1,2]. Medicinal plants possess an important position in the drug discovery and many modern drugs have their origin in traditional medicine of different cultures. Hence, regardless of the advantages of the synthetic and combinatorial chemistry as well as molecular modeling, medicinal plants remain an important source of new drugs, new drug leads, and new chemical entities [3,4]. It was reported that out of over 800 new chemical entities introduced between 1981 and 2002 nearly the half were natural products and semi-synthetic natural products [5]. Cancer is a multistep disease developed by environmental, physical, chemical, metabolic, and genetic factors. Cancer is a disease which involves cells growing out of control resulting in tissue growth regulation failure. For a normal cell to transform in to cancer cell, the genes which regulate cell growth and differentiation must be altered [6]. The causes of cancer are diverse, complex, and partially understood. Many things are known to increase the risk of cancer, including tobacco use, dietary factors, certain infections, and exposure to pollutants [7]. Conventional treatment of cancer includes interventions such as psychological support, surgery, radiotherapy, and chemotherapy [8]. At present, the most frequently used cancer chemotherapy includes natural anticancer agents. However, due to increasing rate of mortality associated with cancer and adverse or toxic side effects of cancer chemotherapy and radiation therapy has greatly facilitated efforts in the search for more effective and novel secondary metabolites as anticancer lead molecules for some time. The plant extracts have conventionally been screened for such findings. Herbal medicine constitutes a major substitute for cancer prevention and treatment in anomalous countries around the globe. The effect of plant extracts as anticancer was widely studied due to their low toxicity and side effects. Due to the aforementioned concerns, such studies investigating medicinal plants have been steadily held with interests. At present, the number of plants reported to possess anticancer properties are more than 3000 [9,10]. The mangroves exist under stressful conditions such as extreme environments, high concentration of moisture, high and low tides of water and abundant living microorganisms, and insects. They thrive in a very peculiar environment and serve as a bridging ecosystem between freshwater and marine systems. These have imposed several modifications in these plants. They possess modifications to establish water and salt economy. There are modifications or alterations in other physiological processes such as carbohydrate metabolism or polyphenol synthesis and due to these reasons; they possess chemical compounds which protect them from these destructive elements. The genus Avicennia is a pioneer group of dominant mangrove species with potential medicinal values. Avicennia alba is a type of tropical mangrove plant and classified to the family Acanthaceae. The plant is found in south and south east Asia, the islands of the south Pacific Ocean and Australia [11].

It is a native of India and is distributed in coastal regions of south Indian mangrove forests [12]. Its widespread root system with large numbers of pneumatophores helps to stabilize new deposits of sediment and is highly tolerant to saline environment [13]. It is used for the treatment of several types of diseases such as sexual disorders, scabies, rheumatism, pananalgesia, asthma, and snake-bites and ulcer. The resin of seeds and leaves is used in traditional medicine as contraceptive. Various studies have reported that the extract of A. alba shows broad range of biological activities, such as anticancer, anti-inflammatory, antimicrobial, antioxidant, and analgesic. The previous phytochemical studies on the plant have reported in the isolation of steroids, triterpenes, saponins, flavonoids, alkaloids, and tannins. Three naphthaquinones and their analogs such as...
The collected plant material was identified and its authenticity was confirmed by Prof. G. Mohana Narasimharao, Department of Botany, College of Science and Technology, Andhra University, Visakhapatnam. The herbarium voucher specimen has been kept in Pharmacognosy and phytochemistry laboratory, Andhra University for further reference. Freshly collected plant material was cleaned to remove adhering dust by washing under running water and then dried under shade. The dried sample was powdered weighing about 4 kg and used for further studies.

**Solvent extraction**

The air dried, powdered stem, and leaves (1 kg) was macerated using methanol (3 l) for a period of 3 days in room temperature and was filtered using No.1 Whatman filter paper. The extract was then vacuum dried in rotary vacuum evaporator and used for further studies.

**Cell lines and culture conditions**

The cell line used for the study were HeLa and MCF-7, human procured from NCCS, Pune. The cell lines were maintained in 96 wells micro titer plate containing MEM media supplemented with 10% heat inactivated fetal calf serum, containing 5% of mixture of Gentamicin (10 µg), Penicillin (100 Units/ml), and Streptomycin (100 µg/ml) in the presence of 5% CO₂ at 37°C for 48–72 h.

**In vitro cytotoxicity [15]**

Common basic steps that are present in in vitro cytotoxic activity include: Isolation of cells, incubation of cell lines with drug for appropriate period of time, assessment of cell survival, and interpretation of result. This is a colorimetric assay [16] that measures the reduction of yellow MTT by mitochondrial succinate dehydrogenase. The MTT enters the cells and passes into the mitochondria where it is reduced to an insoluble, colored (dark purple) formazan product. The cells are then solubilized with an organic solvent (e.g. dimethyl sulfoxide [DMSO], Isopropanol) and the released, solubilized formazan reagent is measured spectrophotometrically. Since reduction of MTT can only occur in metabolically active cells, the level of activity is a measure of the viability of the cells. In vitro growth inhibition effect of test compound was assessed by calorimetric or spectrophotometric determination of conversion of MTT into “Formazan blue” by living cells. Remove the supernatant from the plate and add fresh MEM solution and treat with different concentrations of extract or compound appropriately diluted with DMSO. Control group contains only DMSO. In the study, 10, 20, 25, 30, and 50 µl of the stock solution (10 mg/ml prepared in DMSO) were added to respective wells containing 100 µl of the medium. Hence, the final concentrations were 10, 20, 25, 30, and 50 µg/ml. After 48 h incubation at 37°C in a humidified atmosphere of 5% CO₂ stock solution of MTT was added to each well (20 µl, 5 mg/ml in sterile phosphate-buffered saline) for further 4 h incubation. The supernatant carefully aspirated, the precipitated crystals of “Formazan blue” were solubilized by adding DMSO (100 µl) and optical density was measured at wavelength of 570 nm using LISA plus. The results represent the mean of five readings. The concentration at which the OD of treated cells was reduced by 50% with respect to the untreated control was determined by below formula.

\[
\% \text{ Inhibition} = \frac{100 - (\text{Mean abs OD Test sample} \times 100)}{\text{Mean abs OD control}}
\]

To obtain IC₅₀ values, absorbance was measured at 570 nm in an ELISA multiplate reader.

**RESULTS AND DISCUSSION**

Anticancer activity of methanolic extract of *A. alba* on HeLa cell lines (µg)

---

Michael Asian J Pharm Clin Res, Vol 14, Issue 6, 2021, 73-79
Anticancer activity of methanolic extract of *A. alba* MCF-7 cell lines

Fig. 20: Cisplatin Standard 2.5
Figs. 1 and 2 show that anticancer activity of methanolic extract of *A. alba* was conducted with appropriate positive control (Cisplatin) which yielded results on Hela and MCF-7 cell lines. It was found that the methanolic extract of *A. alba* exhibited more activity against hela cell lines than MCF-7 cell lines. The inhibitory effect of this methanolic extract was observed to be a little bit weaker than that shown by Cisplatin (standard) but was found to be reasonable while inhibiting Hela cell lines when compared. The results were shown in tables. From the results, it is clear that IC\textsubscript{50} concentration of all fractions is less than or equal to 50 µg/ml, that is, the extract is more preferably inhibiting the growth of cancer cells rather than killing the cells as the extract requires very high concentration to kill the cancerous cells when compared to standard drug cisplatin which has IC\textsubscript{50} concentration 7.5 µg/ml. While coming to growth inhibition, *A. alba* inhibited the hela cell lines better than the MCF-7 cell lines. The methanolic extract of *A. alba* showed total growth inhibition of 63.21% and 47.53% at 50 µg/ml against HeLa and MCF-7 cell lines, respectively, at 33.1 µg/ml against HeLa cell lines. The histopathology studies show an insight to a clearer picture of how the cells growth is controlled. The figures from 3 to 24 depicts the activity of plant on cell lines based on concentration.

**CONCLUSION**

The methanolic extract of *A. alba* exhibited more activity against HeLa cell lines than MCF-7 cell lines. The inhibitory effect of this methanolic extract was observed to be inferior to Cisplatin (standard) but was found to be sensible while inhibiting HeLa cell lines on comparison with standard. From the results, it was clear that IC\textsubscript{50} concentration of all fractions was less than or equal to 50 µg/ml, that is, the extract was comparatively inhibiting the growth of cancer cells at a very low concentration (20 and 50 µg/ml). *A. alba* inhibited the HeLa cell lines better than the MCF-7 cell lines. The methanolic extract of *A. alba* inhibited maximum cell growth of 63.21% and 47.53% at 50µg/ml against HeLa and MCF-7 cell lines, respectively. Methanolic extract of *A. alba* showed IC\textsubscript{50} concentration of 20 µg/ml for HeLa and 50 µg/ml for MCF-7 cell lines. Standard drug showed IC\textsubscript{50} values at a concentration of 7.5 µg/ml.

The IC\textsubscript{50} values at low concentrations of plant extract suggests that the plant was considered to be active on cancerous stem cells and the extract is safe with no side effects when compared with cisplatin as the standard drug was synthetic and of high purity and may cause side effects.

Therefore, from the above results it was clear that the plant *A. alba* was having cytotoxicity activity against the HeLa and MCF-7 cell lines and supports the folkloric claims. The histopathology studies show an insight to a clearer picture of how the cells growth is controlled. The outcome of the present study encourages to carry out further studies to be extended for other cell lines and in vivo cytotoxicity investigation required to identify anticancer activity. This also enabled to go further into the molecular level to identify different compounds present in the plant source.
