ABSTRACT

Hydrogenases are metalloenzymes that reversibly catalyse the oxidation or production of molecular hydrogen (H<sub>2</sub>). Amongst a number of promising candidates for application in the oxidation of H<sub>2</sub> is a soluble [Ni–Fe] uptake hydrogenase (SH) produced by *Cupriavidus necator* H16. In the present study, molecular characterisation of the SH operon, responsible for functional SH synthesis, was investigated by developing a green fluorescent protein (GFP) reporter system to characterise P<sub>SH</sub> promoter activity using several gene cloning approaches. A P<sub>SH</sub> promoter-gfp fusion was successfully constructed and inducible GFP expression driven by the P<sub>SH</sub> promoter under de-repressing conditions in heterotrophic growth media was demonstrated in the recombinant *C. necator* H16 cells. Here we report the first successful fluorescent reporter system to study P<sub>SH</sub> promoter activity in *C. necator* H16. The fusion construct allowed for the design of a simple screening assay to evaluate P<sub>SH</sub> activity. Furthermore, the constructed reporter system can serve as a model to develop a rapid fluorescent based reporter for subsequent small-scale process optimisation experiments for SH expression.

INTRODUCTION

Hydrogenases are ubiquitous enzymes with reversible hydrogen oxidation or production activity (Schlegel, Kaltwasser & Gottschalk, 1961; Friedrich, Friedrich & Bowien, 1981). A wide variety of H<sub>2</sub> oxidizing organisms including aerobes, anaerobes, autolithotrophs, heterotrophs, fermentative, photosynthetic and thermophilic microorganisms, have been described and are capable of producing and utilising endogenous uptake (H<sub>2</sub> oxidising) hydrogenases. [Ni–Fe] hydrogenases are the best studied class of the uptake hydrogenases, that are characterised by their H<sub>2</sub> oxidation activity and tolerance to molecular O<sub>2</sub>. These hydrogenases consist of a large subunit hosting the [Ni–Fe] active site and a small subunit housing the Fe–S cluster (Vignais, Billoud & Meyer, 2001; Vignais & Colbeau, 2004). The Knallgas bacteria *C. necator* H16 (formerly *Ralstonia eutropha* or *Alcaligenes*

How to cite this article Jugder et al. (2016), Construction and use of a *Cupriavidus necator* H16 soluble hydrogenase promoter (P<sub>SH</sub>) fusion to *gfp* (green fluorescent protein). *PeerJ* 4:e2269; DOI 10.7717/peerj.2269
*eutropha* is a chemolitho-autotrophic proteobacterium that is capable of growing both autotrophically using molecular hydrogen as the sole energy source and heterotrophically using organic compounds as the energy source (*Pohllmann et al., 2006*). *C. necator* H16 hosts three distinct O$_2$-tolerant hydrogenases (*Burgdorf et al., 2005*); a membrane-bound hydrogenase (MBH), a soluble hydrogenase (SH) and a regulatory hydrogenase (RH). Under heterotrophic growth conditions, the expression of [Ni–Fe] uptake hydrogenases in *C. necator* H16 is induced on poorly utilised carbon sources (e.g., glycerol). Culture of this organism in minimal medium FGN (fructose-glycerol-nitrogen) is characterized by initial growth on the preferred fructose carbon source with hydrogenase expression repressed, followed by de-repression of hydrogenase expression as the organism switches to growth on the less-preferred substrate glycerol upon fructose exhaustion (*Schlegel, Kaltwasser & Gottschalk, 1961*; *Friedrich, Friedrich & Bowien, 1981*). In terms of potential application, oxygen-tolerant soluble hydrogenases (such as that produced by *C. necator*) show tremendous promise as bioelectrocatalysts in hydrogen fuel cells (*Lamle, Albracht & Armstrong, 2004*; *Vincent et al., 2005*; *Jugder et al., 2013*) and for mediating reduction reactions such as the reduction of NAD$^+$ (*Burgdorf et al., 2005*).

The gene clusters for the three hydrogenases of *C. necator* H16 occupy a region of approximately 90 kbp of the megaplasmid pHG1. The SH is one of the most promising candidates for application in H$_2$-based technologies owing to its H$_2$ oxidation activity, oxygen tolerance, relatively favourable purification process and high expression under heterotrophic growth conditions (*Burgdorf et al., 2005*). The structural and accessory hox genes and maturation hyp genes of the SH reside on the large SH operon (10 kb) (*Schwartz et al., 2003*; *Schwartz, 2009*). A strong promoter, P$_{SH}$, for these genes was identified in an upstream region of hoxF by primer extension analysis. The P$_{SH}$ promoter is recognised by the sigma factor $\sigma^{34}$ (RpoN) of the RNA polymerase and its sequence was proposed as 5'-TTGGCGACATCCTGC-3' (*Schwartz, Gerischer & Friedrich, 1998*). It has been well reported that one of two physiological conditions must be met to induce/de-repress the P$_{SH}$ promoter and subsequently express the hydrogenase genes in *C. necator* H16. Under the first condition, H$_2$ must be available in the growth media and typically a mixture of H$_2$, CO$_2$ and O$_2$ with a volume ratio of 8:1:1 (autotrophic growth) has been employed widely to achieve induction in defined media. The second alternate inducing condition is achieved by the absence of preferentially utilized carbon and energy sources, such as fructose, in the medium which is conveniently achieved by using FGN medium whereby substrate shift occurs from fructose to glycerol under heterotrophic conditions (*Friedrich, Friedrich & Bowien, 1981*; *Schlegel, Kaltwasser & Gottschalk, 1961*; *Jugder et al., 2015*).

The use of reporter genes fused to a gene of interest has been widely reported for studying gene expression and promoter activity in a diverse array of living organisms. These reporters can be classified into conditional and non-conditional genes based on their need of an external substrate for detection (*Xiong et al., 2012*). Green fluorescent protein (gfp) has been amongst the most commonly used reporter genes since its first use as a reporter for gene expression in 1994 (*Chalfie et al., 1994*). As a reporter, gfp has great advantages over other reporters such as; direct real-time visualisation in living systems,
little or no cytotoxicity on host cells, small size, and the availability of different mutants with modified spectral wavelengths (Xiong et al., 2012; Carroll & James, 2009). The use of gfp as a reporter gene was studied in C. necator cells with regard to polyhydroxyalkanoate (PHA) production (York et al., 2001; Fuchsli et al., 2003; Barnard et al., 2005). It has been reported that the expression of the gfp gene that is fused to the phaP promoter of phasin proteins, which are directly related to PHA synthesis, can be driven by the phaP promoter and thereby used as a tool to monitor PHA production. Nevertheless, PSH promoter-driven GFP expression has not been reported in C. necator, to our knowledge.

We herein designed a recombinant reporter system to analyse the PSH promoter activity in C. necator H16 utilising a mutant recombined operon comprising of a gfp gene assembled in a suicide vector, which is integrated within the megaplasmid pGH1. This tool allows for the analysis of potential growth conditions that de-repress promoter activity by monitoring the induction of the gfp gene expression. Employing qRT-PCR methodologies is time consuming and cannot effectively be applied to broad screening strategies to determine conditions associated with elevated SH production. The use of a simple visual reporter, such as GFP, would potentially be a time-saving and robust screening tool to investigate alternative growth conditions for potentially obtaining a higher yield of the SH from C. necator H16 by measuring GFP fluorescence emitted by the generated mutant strains. Increased SH specific productivity would also potentially improve recovery of active soluble hydrogenase.

MATERIALS AND METHODS

Bacterial strains, growth conditions, plasmids and oligonucleotides

C. necator H16 (Cupriavidus necator, DSM 428) was routinely cultivated heterotrophically in minimal medium FGN as described in our previous work (Jugder et al., 2015; Jugder et al., 2016). The transconjugants were also grown under a hydrogenase repressing condition in FN medium (FGN medium without glycerol) and hydrogenase de-repressing condition in GN medium (FGN medium without fructose). E. coli strains were grown in Luria–Bertani medium (LB) except for conjugation processes where low-salt LB supplemented with 5% sucrose was used. E. coli DH10B containing the pJQ200mp18 suicide vector (ATCC 77485) was cultivated on LB media supplemented with gentamicin (15 µg/mL). E. coli S17-1 was maintained in LB media supplemented with trimethoprim (10 µg/mL). For blue/white screening, 100 µg/mL of ampicillin, 80 µg/mL of X-gal (5-bromo-4-chloro-3-indolyl-ß-d-galactopyranoside) and 0.5 mM IPTG (isopropylthio-ß-galactoside) were added to the LB agar media. SOC medium was used for transformation of E. coli JM109 High Efficiency Competent Cells. C. necator and E. coli strains were cultivated at 30 and 37 °C, respectively. The strains, plasmids and primers used in this study are listed in Table 1.

DNA isolation, manipulation and amplification

The UltraClean® Microbial DNA Isolation Kit (MO BIO Laboratories, Carlsbad, CA, USA) was used for genomic DNA preparation from C. necator H16. After separation of PCR amplified products by agarose gel electrophoresis, DNA fragments were excised from

the gel and extracted using the Wizard SV Gel and PCR Clean-up system kit (Promega, Sunnyvale, CA, USA) following the manufacturer’s protocol. The same kit was also used for clean-up of the pJQ200mp18 vector following the restriction enzyme digestion. The Wizard® Plus SV Minipreps DNA Purification System (Promega, Sunnyvale, CA, USA) was used to isolate plasmids from microorganisms according to the manufacturer’s instruction. For DNA amplification, 2X PCR Master Mix (Promega, Sunnyvale, CA, USA) was used. For proof-reading PCR, Phusion™ High-Fidelity DNA Polymerase (Finnzymes, Espoo, Finland) was used with 5x Phusion HF Buffer supplied. The cycling conditions vary depending on the purpose. The ABI 3730 Capillary Sequencer with BigDye™ Terminator Cycle Sequencing Ready Reaction kit v.3.1 (Applied Biosystems) was used for sequencing PCR of cloned insert DNA according to the manufacturer’s instructions.

Hydrogenase activity assay
Soluble hydrogenase assays were performed as described previously in 50 mM H₂-saturated Tris/HCl buffer at pH 8.0 (Jugder et al., 2015; Jugder et al., 2016). NAD⁺ was used as an artificial electron acceptor and its reduction to NADH was measured spectrophotometrically at 340 nm.

Construction of a PSH promoter-gfp fusion element
An overview of the creation of the PSH promoter-gfp fusion elements is shown in Fig. 1. A 353 bp fragment, phosphorylated at the 5’ end, containing the region upstream of hoxF (nucleotides 79,365 and 79,382, sequence numbering according to GenBank entry AY305378.1) up to the translational stop codon of the previous ORF (nucleotides 79,685 and 79,711, sequence numbering according to GenBank entry AY305378.1) was amplified in the first PCR by using primers F-upstream and R-upstream, and C. necator H16 chromosomal DNA as template. Similarly, a 784 bp fragment, containing a gfp plus the portion of the region post hypF2 amplicon (nucleotides 89,228 and 89,285, sequence numbering according to GenBank entry AY305378.1) and phosphorylated at the beginning, was generated from pGLO template, which harbours the gfp gene, by using primers F-gfp and R-gfp. Thus, all transcriptional control and stop elements of the SH are located in the regions amplified by these primer pairs. These fragments were, after gel-extraction, ligated using T4 DNA Ligase (Promega) and subjected to a further PCR by using primers F-upstream and R-gfp-truncated to amplify the ligation product of the expected size of 1,137 bp (Fig. S1). The gel-purified ligated fragment was sub-cloned into the pGEM-T Easy vector and the resultant recombinant vector was designated as pGEM-PSH::gfp (Fig. 1B), which was used for transformation of E. coli JM109. The transformation culture was plated in duplicate on LB/ampicillin/IPTG/X-Gal plates for further blue-white screening. Sequencing PCR was performed on purified pGEM-PSH::gfp vectors from white colonies employing the pUC/M13 Sequencing Forward and Reverse Primers.

The pJQ200mp18 suicide vector was used in this work to carry out gene replacement and mobilization experiments (Quandt & Hynes, 1993). Mini-preps of the pJQ200mp18 suicide vector and pGEM-PSH::gfp vector DNA were digested with PstI restriction
Figure 1  Overview of the molecular cloning method employed in this study. (A) Flow diagram of the steps involved in the generation of the target sequence to be fused. Step 1: the PCR amplification of the region upstream of hoxF up to the translational stop codon of the previous ORF (phosphorylated at the 5′ end of the non-coding strand) by using primers F-upstream and R-upstream and template C. necator H16 DNA and a gfp plus the portion of the region post hypF2 amplicon (phosphorylated at the 5′ end of the coding strand) by using primers F-gfp and R-gfp and template pGLO. Step 2: ligation of PCR products. Step 3: secondary amplification of the ligated product to generate the target DNA. (continued on next page...)
endonuclease and dephosphorylated using Antarctic Phosphatase for further ligation to yield the recombinant vector pJQ200mp18::gfp, which was used to transform E. coli JM109. Following blue/white screening (LB/gentamicin/IPTG/X-Gal selective plates), the recombinant vector purified from E. coli JM109 was used to transform E. coli S17-1 competent cells via a heat shock at 42 °C for 1 min. The transformed competent cells were plated onto LB/gentamicin/trimethoprim/IPTG/X-Gal plates, as E. coli S17-1 harbouring pJQ200mp18 is resistant to gentamicin (Quandt & Hynes, 1993) and trimethoprim (Simon, Priefer & Puhler, 1983). The mobilisable suicide vector, pJQ200mp18::gfp, was transferred from E. coli S17-1 to C. necator H16 by spot mating (Dernedde et al., 1996). Transconjugants were selected by plating serial dilutions on low-salt LB plates containing 5% sucrose. After 3–5 days of incubation at 30 °C, transconjugants appeared and colony PCR was used to screen transconjugants, with primers F-gfp and R-recombination. Transconjugants were inoculated into 5 mL of FGN media and incubated overnight at 30 °C. Genomic DNA from select transconjugants was subjected to final PCR using the primers F-gfp and R-recombination, and primers F-upstream and R-gfp-truncated to amplify DNA fragments of approximate 800 bps and 1.14 kbps, respectively, in order to confirm final successful recombination.

**Transcriptional analysis**

Total RNA extraction and subsequent cDNA synthesis were performed using the TRIzol Plus RNA Purification Kit (Life Technologies, Carlsbad, CA, USA) and the SuperScript III First-Strand Synthesis System (Life Technologies), respectively, as described in Jugder et al. (2015). Expression levels of the hoxF gene encoding HoxF protein (NAD-reducing hydrogenase diaphorase moiety large subunit) of the SH in different growth phases of wild-type C. necator were analysed using qRT-PCR with primers hoxF_fwd and hoxF_rev. In the conjugated strains, expression of gfp gene was examined with gfp_fwd and gfp_rev primers. The gyrB gene was used as an internal reference gene due to its constitutive expression. qRT-PCR was performed on a Rotor-Gene RG-3000A cycler (Qiagen, Chadstone Centre, VIC, Australia) using the SensiFAST SYBR No-ROX Kit (Bioline, Eveleigh, NSW, Australia) as described elsewhere (Jugder et al., 2015).

**Fluorescence microscopy examination of the transconjugants to detect the presence of GFP**

The cultures that were inoculated from single colonies from the conjugated strains were grown overnight in 5 mL GN (Glycerol as sole carbon source, hydrogenase derepressing condition) and FN media (Fructose as sole carbon source, hydrogenase repressing condition). The overnight cultures were placed on glass slides with cover slips and examined for brightfield imaging under light microscope settings with 10x and 50x.
objectives for locating the cells. Subsequently, the cells were examined for fluorescence by using the “WB” filter tube, which is a combination of a BP450-480 excitation filter, a DM500 dichroic mirror and a BA515 barrier filter (filter cube WB). This combination elicted a green fluorescence of the transconjugants expressing GFP. The images of the GFP-expressing cells under fluorescence settings were obtained using DP Manager v3.3.1.222 software (Olympus).

Flow cytometry analysis of GFP
The cultures that were inoculated from single colonies from the conjugated strains were grown overnight in 5 mL GN (hydrogenase de-repressing) and FN (hydrogenase repressing) media. After two successive 400-fold dilutions, $5 \times 10^4$ cells from each pool were analyzed using a Becton-Dickinson FACS Caliber flow cytometer, and fluorescence (488-nm excitation, 520-nm emission) was scaled by scattering to compensate for differences in cell morphology and size. One hundred thousand events (cells) were counted for each sample. Experiments were performed in triplicate unless otherwise stated.

Purification of GFP isolated from transformed C. necator
The cell pellets were harvested by centrifugation at 5,500 g for 15 min at 5 °C, and stored at −80 °C. Cells were disrupted by sonication and the cell-free extract was centrifuged (100,000 g, 30 min at 5 °C). The remaining supernatant was loaded onto a 10-ml volume metal affinity resin (Talon resin; Clontech) equilibrated in buffer containing 150 mM NaCl, 100 mM HEPES–NaOH, pH 7.5. Unbound proteins were washed off using the same buffer containing 10 mM imidazole. The bound protein was then eluted with a buffered solution composed of 200 mM imidazole, 150 mM NaCl, 100 mM HEPES–NaOH, pH 7.5. The solution containing the precipitated protein was centrifuged, and the supernatant was discarded. The precipitate was progressively dissolved in 20 mM HEPES–NaOH, pH 7.5. The protein solution was dialyzed overnight against a 500-fold (vol/vol) excess of the same solution.

Absorption and fluorescence excitation and emission spectra
Samples of purified GFP were diluted to approximately 4.5 µM in buffered solution (containing 10 mM glycine, 10 mM sodium citrate, 10 mM sodium phosphate, and 5 mM Tris-HCl). A fluorometer (Fluorostar Optima) was used to obtain the emission spectrum of the commercial GFP and the GFP extracted and purified from the transconjugant C. necator H16. Measurements were obtained using excitation and emission wavelengths, bandpass, and integration times of 392 nm, 510 nm, 3 nm, and 0.5 s, respectively.

Fluorescence quantitation in wildtype and transformed C. necator
The fluorescence intensity of GFP in fixed cells was measured with a Fluoromax-2 spectrofluorometer using the Datamax for Windows software interface (Instruments S.A. Inc., Edison, NJ, USA). A protein assay on lysates of the cell samples was carried out prior to normalise cell loading for gfp fluorescence determination, using the Pierce BCA Protein Assay Kit (Thermo Scientific, Waltham, MA, USA). The relative fluorescence unit (RFU) is defined as the culture fluorescence relative to culture concentration (OD$_{600nm}$).
RESULTS AND DISCUSSION

In this study, the transcriptional reporter method was employed to construct the $P_{SH}$ promoter-$gfp$ fusion in the megaplasmid pHG1 of $C. necator$ H16 to analyse promoter activity. The molecular cloning method was designed to generate, by PCR, the entire sequence of the 5’ upstream elements which were subsequently fused to the $gfp$ gene that was combined with 3’ downstream elements of the SH operon by establishing a rapid and robust cloning approach which is summarised in Fig. 1. The $gfp$ gene from a commercially available pGLO vector was fused to the $P_{SH}$ promoter of the SH operon in place of the first ORF ($hoxF$) followed by 3’ downstream elements following the final ORF ($hypF2$) of the same operon. The results confirmed that the fusion elements recombined with the pHG1 megaplasmid of wild-type $C. necator$ by a means of gene replacement at the site of the SH operon elements. The resulting reporter construct was capable of being induced under the hydrogenase de-repressing condition (GN medium) in the transconjugant derivative cells which led to detectable fluorescence signals from the GFP expressed.

Initially, the 784 bp amplicon representing a GFP product combined with the region downstream of $hypF2$ (using the primers $F-gfp$ and $R-gfp$ as well as pGLO vector) and the 353 bp amplicon from the region upstream of $hoxF$ (using the primers $F-upstream$ and $R-upstream$, and $C. necator$ H16 chromosomal DNA as template) were obtained (Fig. S2A). The ligation reaction of these two fragments theoretically can result in three possible ligated products joined via the 5’-phosphorylated ends (Fig. S2B) as follows: (i) between two $N$-terminal products, (ii) between an $N$-terminal product and a $C$-terminal product and (iii) between two $C$-terminal products. The second product is the desired ligation product with a calculated size of 1,137 bp which was excised from a gel for further PCR amplification by using the primers $F-upstream$ and $R-gfp-truncated$ (Fig. S2B). In Fig. S3, gel images of the results of each cloning step are shown: the colony PCR product with the expected theoretical size (1,137 bp) generated from a JM109 transformant harbouring the pGEM-SH::gfp vector (Fig. S3A), the PstI-digested fragments of the isolated pGEM-SH::gfp vector and the pJQ200mp18 suicide vector prior to the ligation to yield the vector pJQ200mp18-SH::gfp (Fig. S3B) and confirmation of successful sub-cloning of the resulting recombinant suicide vector by PstI digestion (Fig. S3C). The colony PCR product from $E. coli$ S17-1 transformed with the pJQ200mp18-SH::gfp vector using the primers $F-upstream$ and $R-gfp-truncated$ enabled rapid screening for successful transformation (Fig. S3D). Furthermore, the colony PCR product with the estimated size of 800 bp from a transconjugant $C. necator$ H16::gfp cell after spot-mating by using primers $F-gfp$ and $R-recombination$ (Fig. S3E) on a gel indicated successful gene replacement on the megaplasmid pHG1. These transconjugants were designated as $C. necator$ H16::gfp cells. Lastly, PCR was performed using two primer pairs ($F-upstream$ and $R-gfp-truncated$, as well as $F-gfp$ and $R-recombination$) on genomic DNA prepared from the transconjugant colonies which confirmed successful transformation (Fig. S3F).

Following the confirmation of the successful final recombination event, the performance of the transconjugant ($C. necator$ H16::gfp), in producing GFP under control of the $P_{SH}$ promoter, was determined using fluorescence microscopy. Glycerol stocks were
subsequently prepared from cultures derived from single colonies that demonstrated green fluorescence when grown in GN media. Quantitative RT-PCR, flow cytometry and quantitative fluorescence analysis was subsequently undertaken using cultures from these glycerol stocks. Images and flow cytometry data of the cells expressing GFP under the hydrogenase repressing condition (fructose; FN media) and the hydrogenase de-repressing condition (glycerol; GN media) were obtained (Fig. 2). GFP expression was observed visually and by a significant shift in the population, verifying that the P_{SH} promoter from the transconjugated *C. necator* successfully induced GFP production under the selected hydrogenase de-repressing growth condition.

Figure 2  Detection of GFP-expressing *C. necator* H16::gfp cells. The fluorescence images (A, C and E) of the cells with corresponding flow cytometry fluorescence histograms (B, D and F). The GFP signal was not detected from wild-type *C. necator* H16 cells (A and B) and the transformed *C. necator* H16::gfp cells under the hydrogenase repressing condition (growth on fructose) (C and D), whereas the GFP signal was detectable in transformed *C. necator* H16::gfp cells under the hydrogenase de-repressing condition (growth on glycerol) (E and F).
Figure 3  Fluorescence of wildtype (WT) and recombinant C. necator (transformed) in fructose (FN) media and glycerol (GN) media. Specific fluorescence response (RFU) of C. necator H16:gfp (transformed) and non-transformed (WT- wild-type) cells excited at 392 nm under repressing conditions (growth on fructose) and de-repressing conditions (growth on glycerol). Bars represent the mean ± S.E gfp relative fluorescence units obtained from triplicates for each treatment group. Significance *p < 0.01 compared to wild-type C. necator H16 cells in glycerol and fructose, and the transformed C. necator H16:gfp cells under the hydrogenase repressing condition (fructose). P-values were calculated using one way analysis of variance (ANOVA) followed by a t-test.

The emission characteristics of the recombinant GFP isolated from the transconjugants confirmed its authenticity, with emission maxima observed at excitation wavelengths of 392 and 475 nm (Fig. S4) coinciding exactly with that of the native GFP. In the fluorescence plate assay, a significant increase in GFP expression was demonstrated under PSH de-repressing conditions (growth in GN media) for the transformed population (Fig. 3).

A time course study in FGN media (Fig. 4) showed increasing protein expression (soluble hydrogenase in the WT strain and GFP fluorescence in the transformed strain) and increased fold change in respective mRNA levels, as cells switched from growth on fructose \((t = 10 \text{ h})\) to growth on glycerol \((t = 16 \text{ h}, 24 \text{ h and 36 h})\). The gene hoxF was approximately 1.4, 2.1 and 3.5-fold up-regulated in the cells harvested at 16 h, 24 h and 36 h where the expression of SH was assumed to be induced, in comparison to the cells at 10 h (Fig. 4A). The SH expression was also demonstrated as specific SH activity increased in accordance with the increase in abundance of hoxF mRNA. In parallel, the gfp gene expression was investigated in the conjugated cells at the transcriptional level (Fig. 4B). We observed the up-regulation of the gfp gene with an approximate 8.9-fold increase at 36 h. Observations made in the time course of the expression pattern of the genes hoxF and gfp
confirmed that $P_{SH}$ promoter, in our constructed strain, is responsive to the de-repression upon carbon source change in a similar manner. Together, these findings confirm the utility of the transformed *C. necator* H16::gfp for future $P_{SH}$ activity screening.

To our knowledge, this is the first report of a successful fluorescent reporter system to study $P_{SH}$ promoter activity in *C. necator* H16. Understanding the environmental factors in the regulation of SH expression is of increasing interest and the availability of versatile monitoring methods is crucial. The system developed in this study should allow for the conduct of factorial experiments and high-throughput assays in a microplate format that employs the recombinant *C. necator* H16::gfp cells to explore alternative...
growth conditions and rapidly estimate SH promoter activity. Furthermore, there is potential to use this construct in transposon mutagenesis experiments to identify new SH regulators by monitoring a simple fluorescence read-out. This tool has the potential to further assist in investigating the sigma factor, $\sigma^{54}$, which recognises the $P_{SH}$ promoter (Schwartz, Gerischer & Friedrich, 1998). Possible carbon sources could theoretically be identified as ideal candidates to induce strongly the $\sigma^{54}$-dependent $P_{SH}$ promoter. Also, evaluation of site-directed mutagenesis of the $P_{SH}$ promoter or the replacement of the $P_{SH}$ promoter with a more strongly inducible promoter could be facilitated by this reporter system. The generation of these reporter strains is based on recombination events; further characterization of a range of the recombinant transconjugants may also reveal as yet unidentified variants that possess useful traits that may assist in the identification of inducing conditions.

CONCLUSION

In the present study, a system to investigate soluble hydrogenase $P_{SH}$ promoter activity in C. necator H16 was constructed and its functionality was confirmed, developing a $P_{SH}$-GFP fusion protein reporter. A series of molecular cloning steps were employed to replace the ORF of the SH with a gfp gene in the megaplasmid pHG1, and the expression of GFP in response to the de-repression of the SH genes was demonstrated under fluorescence and transcriptional analyses. This construct will enable future studies to design simple screening methods for $P_{SH}$ promoter activity in C. necator H16 cells, further investigations on growth-related optimisation with alternative cultivation conditions and functionality of $P_{SH}$ promoter mutants in C. necator.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

Bat-Erdene Jugder received the provision of an Australian Development Scholarship from AusAID. Nady Braidy is the recipient of an Alzheimer’s Australia Viertel Foundation Postdoctoral Research Fellowship and a National Health and Medical Research Early Career Research Fellowship at the University of New South Wales. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:
AusAID.
Alzheimer’s Australia Viertel Foundation Postdoctoral Research Fellowship.
National Health and Medical Research Early Career Research Fellowship.

Competing Interests

The authors declare there are no competing interests.
Author Contributions

• Bat-Erdene Jugder conceived and designed the experiments, performed the experiments, analyzed the data, contributed reagents/materials/analysis tools, wrote the paper, prepared figures and/or tables, reviewed drafts of the paper.
• Jeffrey Welch conceived and designed the experiments, analyzed the data, wrote the paper, reviewed drafts of the paper.
• Nady Braidy performed the experiments, analyzed the data, contributed reagents/materials/analysis tools, wrote the paper, prepared figures and/or tables, reviewed drafts of the paper.
• Christopher P Marquis conceived and designed the experiments, analyzed the data, contributed reagents/materials/analysis tools, wrote the paper, reviewed drafts of the paper.

Data Availability
The following information was supplied regarding data availability:
Sequence information has been supplied as Supplementary files.

Supplemental Information
Supplemental information for this article can be found online at http://dx.doi.org/10.7717/peerj.2269#supplemental-information.
