Low lying eigenmodes and meson propagator symmetries

C. B. Lang

(Dated: March 16, 2022)

In situations where the low lying eigenmodes of the Dirac operator are suppressed one observed degeneracies of some meson masses. Based on these results a hidden symmetry was conjectured, which is not a symmetry of the Lagrangian but emerges in the quantization process. We show here how the difference between classes of meson propagators is governed by the low modes and shrinks when they disappear.

I. MOTIVATION

Recently it was found that in certain situations a symmetry emerges that relates vector and scalar meson propagators but that is no symmetry of the action. That symmetry was observed in lattice QCD when low lying eigenmodes of the Dirac operator are suppressed either artifici- ally by removing the eigenmodes from the quenched quark propagators \[1\] or naturally in the high temperature phase \[2\] either due to a gap \[3\] or because another rapid decrease towards zero eigenvalues. The symmetry group was called CS (chiral-spin) and has been suggested \[12, 13\] to be \( SU(4) \supset SU(2)_L \times SU(2)_R \times U(1)_A \) mixing the \( u \)- and \( d \)-quarks of a given chirality and also the left- and right-handed components.

We consider the eigenvalues of the hermitian Dirac operator. It is well known that the difference of the susceptibility of, e.g., the propagator of the isovector scalar meson operator and of the isovector pseudoscalar operator are weighted by an eigenvalues density factor (on top of the generic eigenvalue density), that approaches a delta function in the zero mass limit. The approach is similar to the derivation of the Banks-Casher relation for the quark condensate \[14\]. The difference between the scalar and pseudoscalar propagators and susceptibilities has been intensely studied earlier \[15\–17\]. We show here that this property applies to a large set of (scalar, pseudoscalar, vector and axial vector) meson propagator pairs and discuss the conditions for the CS symmetry.

II. NOTATION

A. Dirac operator

We work in Euclidean space-time continuum and will briefly remind on the notation. The tool will be the spectral representation of the Dirac quark and the meson propagator. As there are sums over all (an infinite number of) eigenmodes we need some regularization (e.g., a finite volume lattice) and for this we rely on Fujikawa’s approach \[18\–20\], which we assume implicitly but will omit the actual derivation.

We choose hermitian \( \gamma \)-matrices \( \gamma^\dagger _\mu = \gamma_\mu \) and \( [\gamma_\mu, \gamma_\nu]_+ = 2 \delta_{\mu \nu} \). The fermions are Grassmann fields and the Dirac action

\[
\int d^4x \overline{\psi} (i \gamma_\mu D_\mu + im) \psi
\]

is real. The massless Euclidean Dirac operator \( D \equiv i \gamma_\mu D_\mu \) is hermitian with the eigenvalues

\[
D\psi^{(n)} \equiv \eta_n \psi^{(n)}
\]

The dimension of the eigenvectors is \( n_D n_u n_f \) (Dirac, color, flavor) at each point \( x \in \mathbb{R}^4 \) and there are \( n_D n_u n_f \) eigenvectors as functions of \( x \). Only the Dirac index \( a \) is kept explicitly, the color- and flavor indices are implicit. The non-zero eigenvalues come in pairs as can be seen by multiplying with \( \gamma_5 \):

\[
\gamma_5 D\psi^{(n)} = \eta_n \gamma_5 \psi^{(n)}
\]

\[
\rightarrow D(\gamma_5 \psi^{(n)}) = -\eta_n (\gamma_5 \psi^{(n)}) \, .
\]

We use the notation \( \eta_n \equiv \eta \) with \( \eta_{n} = -\eta_{-n} \) and \( \psi^{(-n)} = \gamma_5 \psi^{(n)} \). The eigenvalues are real and the eigenvectors form an orthonormal basis

\[
\sum_a \int d^4x \overline{\psi}^{(n)} x a \psi^{(k)} x a = \delta_{nk} \, .
\]

We formally regularize by point-splitting such that the Dirac operator becomes a matrix,

\[
D_{xa|yb} \psi^{(n)} yb = \eta_n \psi^{(n)} xa \, .
\]
We define chiral symmetry as the invariance of the massless Dirac operator. The transformation is
\[ \psi(x)' = e^{i\alpha \gamma^5} \psi(x), \quad \bar{\psi}(x)' = \bar{\psi}(x)e^{i\alpha \gamma^5}, \]
\[ \psi(x)' = e^{i\alpha \gamma^5} \psi(x), \quad \bar{\psi}(x)' = \bar{\psi}(x)e^{i\alpha \gamma^5}, \]
where \( \tau_i \) are the generators of \( SU(2)_{\text{flavor}} \) and \( I_f \) the unit matrix in flavor space. The kinetic term of the action is invariant, e.g.,
\[ \bar{\psi} \gamma_{\mu} \psi \rightarrow \bar{\psi} e^{i\alpha \gamma^5} \gamma_{\mu} e^{i\alpha \gamma^5} \psi = \bar{\psi} \gamma_{\mu} \psi \]
The chiral transformation commutes with the Euclidean Lorentz transformations \( O(4) \).

For the discussion it will be useful to split the four-Dirac-components of the eigenvectors into a pair,
\[ \psi^{(n)} = \psi_R^{(n)} + \psi_L^{(n)} \]
with
\[ \psi_R^{(n)} = \frac{1}{2}(1 + \gamma_5)\psi, \quad \psi_L^{(n)} = \frac{1}{2}(1 - \gamma_5)\psi. \]
We choose a chiral basis for the Dirac matrices with \( \gamma_5 = \text{diag}(1, 1, -1, -1) \) such that
\[ \psi_R^{(n)} = \begin{pmatrix} R^{(n)} \\ 0 \end{pmatrix}, \quad \psi_L^{(n)} = \begin{pmatrix} 0 \\ L^{(n)} \end{pmatrix}, \]
and \( R, L \) having two components.

C. CS symmetry

The (hermitian) \( SU(2)_{CS} \) (shorter: CS for “chiral spin”) algebra \[12\] generators are
\[ CS_k : \ T \in \{ \gamma_k, i\gamma_k \gamma_5, \gamma_5 \}, \quad k = 1, 2, 3, 4. \]
We define the transformation guided by the Minkowski version (i.e., that \( \psi \) should transform like \( \psi^\dagger \gamma_4 \))
\[ \psi \rightarrow \psi' = e^{i\alpha T} \psi, \quad \bar{\psi} \rightarrow \bar{\psi}' = \bar{\psi} \gamma_4 e^{-i\alpha T^\dagger} \gamma_4 \]
Then quark - antiquark bilinears transform like
\[ \bar{\psi} O \psi \rightarrow \bar{\psi} |\gamma_4 e^{-i\alpha T^\dagger} \gamma_4| O e^{i\alpha T} \psi \]
where \( T_a, T_b \) are the generators of the algebra CS. Each operator this way is an element of a multiplet. E.g., a CS\(_1\) multiplet might be \( \{ \gamma_2, i\gamma_2 \gamma_5, i\gamma_4 \gamma_2, i\gamma_7 \gamma_1 \} \), which corresponds to \( \rho, \omega, a_1, f_1, b_1, h_1 \) for isovectors and isoscalars.

For \( T = \gamma_5 \) this is the transformation of chiral symmetry \[8\]. Only \( \gamma_5 \) leaves the kinetic term invariant. It turns out that only \( \gamma_5 \) is anomalous giving a factor for the Grassmann path integral integration measure. All CS transformations leave the chemical potential term \( \bar{\psi} \gamma_4 \psi \) invariant. In \[12, 13\] the embedding of \( SU(2)_{CS} \times SU(2)_f \subset SU(2n_f) \) was suggested. In \( SU(4) \) the vector mesons form a 15-plet \( \rho, \rho', b_1, a_1, h_1, \omega, \omega' \) and a singlet \( \{ f_1 \} \).

The CS transformations as a whole are no symmetry of the Dirac action. However, it has been observed, that CS is a symmetry of certain meson and baryon masses, if the low lying (quasi-zero) modes are absent \[8, 15, 21\]. At zero temperature, with artificial removal of low lying modes in the valence sector, confinement seems to persist. Above the chiral temperature the zero modes are suppressed naturally. There are indications that some form of confinement persists as well \[7\].

The chromo-electric observables \( \bar{\psi} \gamma_k \psi \) are symmetric under CS, the kinetic term of the action and the chromo-magnetic terms \( \bar{\psi} \gamma_k \psi \) \( (k = 1, 2, 3) \) are not. Removing the near-zero modes apparently restores the symmetry such that the influence of chromo-magnetism shrinks or disappears. One might conclude that confinement has its origin in the chromo-electric sector, which is symmetric under CS always \[22\].

III. MESON PROPAGATORS

We restrict ourselves to two mass degenerate quark flavors \( u \) and \( d \). As already mentioned, we neglect exact zero modes, either because we are in that topological sector or because they have been removed.

| \( \Gamma_{src} \) | \( \Gamma_{sink} \) | \( i\Gamma_{src} \gamma_5 \) | \( i\gamma_5 \Gamma_{sink} \) | \( s_5 \) |
|-----------------|-----------------|-----------------|-----------------|-------|
| 1               | 1               | 1               | 1               | 1     |
| \( \gamma_k \) | \( \gamma_k \) | \( i\gamma_k \gamma_5 \) | \(-i\gamma_k \gamma_5 \) | -1    |
| \( \gamma_4 \) | \( \gamma_4 \) | \( i\gamma_4 \gamma_5 \) | \(-i\gamma_4 \gamma_5 \) | -1    |
| \( \gamma_k \gamma_j \) | \(-\gamma_k \gamma_j \) | \(-i\gamma_k \gamma_j \) | \(-i\gamma_k \gamma_j \) | 1     |
| \( \gamma_k \gamma_4 \) | \(-\gamma_k \gamma_4 \) | \(-i\gamma_k \gamma_4 \) | \(-i\gamma_k \gamma_4 \) | 1     |

TABLE I. We list the sink and source operator kernels. We also give sign factors \( s_5 \) defined by \( \Gamma \gamma_5 = s_5 \gamma_5 \Gamma \).
We study the propagators for mesons of type $\Psi(\tau \otimes \Gamma)\Psi$ and $\Psi(1_f \otimes \Gamma)\Psi$. The $\Gamma$ are listed in Table I; the choice has been motivated by the discussion of the CS symmetry in Ref. [23]. We emphasize that our results are for the external field $\Gamma$, where $\gamma_s$ refers to Grassmann integration in an external field $A$. We relate source and sink by $\Gamma_{\text{src}} \equiv s_1 \Gamma_{\text{src}}$, see Table I. For degenerate quark masses $D_{\gamma^{-1}} = D_{g^{-1}}$. With the spectral representation for $D^{-1}$ the meson propagator becomes

$$P_c(\Gamma, x, y) = s_r \sum_{n,k} \frac{1}{(\eta_n + \Gamma_n)(\eta_k + \Gamma_k)}$$

$$= s_r \sum_{n,k} \frac{1}{(\eta_n + \Gamma_n)(\eta_k + \Gamma_k)}$$

$$= \frac{1}{(\eta_n + \Gamma_n)(\eta_k + \Gamma_k)}$$

The isoscalar propagators have also disconnected contributions proportional to

$$P_d(\Gamma, x) = s_r \text{tr}[D_{\gamma^{-1}}^{-1}(x, z, x, a)b \Gamma_{\text{dirac}}]^{\text{tr}[D_{\gamma^{-1}}^{-1}(y, c,d)\Gamma_{\text{dirac}}]}$$

Like other expressions used here, this has to be regularized (e.g., by lattice regularization) and there are standard tools to do this (e.g., $\Psi(\tau \otimes \Gamma)\Psi$ and $\Psi(1_f \otimes \Gamma)\Psi$, the results and conclusions presented here are not affected.

We will find useful the identities

$$\psi_{a,b}^{(n)} \Gamma_{\text{dirac}} \psi_{x,b}^{(k)} = \psi_{a,b}^{(n)} (\gamma_5 \Gamma_5)^{ab} \psi_{x,b}^{(k)}$$

$$\psi_{a,b}^{(n)} \Gamma_{\text{dirac}} \psi_{x,b}^{(k)} = \psi_{a,b}^{(n)} (\gamma_5 \Gamma_5)^{ab} \psi_{x,b}^{(k)}$$

$$\psi_{a,b}^{(n)} \Gamma_{\text{dirac}} \psi_{x,b}^{(k)} = \psi_{a,b}^{(n)} (\gamma_5 \Gamma_5)^{ab} \psi_{x,b}^{(k)}$$

where $\gamma_5 \Gamma_5 = s_5 \Gamma$ (see Table I).

The difference between two meson propagators depends on

- the generic distribution density of eigenvalues $\rho(m, \eta)$ (which depends on the gauge configuration and the Dirac operator),
- the values of the overlap matrix elements $\psi^\Gamma \psi$ (which are bounded from above due to the orthogonality and normalization of the eigenvectors), and
- a weight function discussed below.

The generic distribution of eigenvalues $\rho(m, \eta)$ is needed only for the small eigenvalues, where it vanishes fast enough or there is even a gap, the relevant cases of this study. The bulk behavior is inessential.

We focus here on the third factor. As derived in the Appendix the functions (see Figs. [1])

$$g(m, \eta) \equiv \frac{m}{m^2 + \eta^2}, \quad h(m, \eta) \equiv \frac{\eta}{m^2 + \eta^2}, \quad (\eta > 0)$$

turn up in the sums over eigenvalues in the next section. They are essential for the argumentation. Both functions give large weight to contributions from small $\eta$. The function $g$ is peaked at $\eta = 0$ and approaches $(\pi/2)\delta(\eta)$ for small masses $m \to 0$; for large $\eta$ it falls like $1/\eta^2$. Propagator differences weighted by $g$ vanish for small $m$ if there is a gap in the density $\rho(m, \eta)$ at low lying eigenmodes, i.e., if there are no eigenvalues below some value, or if the density vanishes fast enough for $\eta \to 0$. Propagators that differ only by terms proportional to $g$ will be called $g$-equivalent.

The function $h$ is peaked at $\eta = m$ and falls like $1/\eta$ for large $\eta$. Compared to $g$ this behaviour may not suppress the higher modes enough, depending on the Dirac structure. Propagators that differ also by terms proportional to $h$ will be called $h$-equivalent. For these the existence of a gap at low eigenvalues is not sufficient to obtain propagator agreement and more conditions have to be met.

In the next section we discuss the main results. The full derivations can be found in the appendix. The resulting equivalences between the meson propagators are listed in Table II and shown in Fig.s 2 and 3.

A. $g$-equivalent mesons

1. $\Gamma$ vs. $i\Gamma_5$

For $\Gamma \in \{1, \gamma_5, \gamma_4, \gamma_5 \gamma_4, \gamma_5 \gamma_7, \gamma_5 \gamma_6 \}$ the difference between meson isovector propagators is

$$P_c(\Gamma, x, y) - P_c(i \Gamma_5, x, y) =$$

$$-8 \sum_{n=0, k>0} g(m, n, \eta_k)$$

$$= s_{5} \sum_{n=0, k>0} g(m, n, \eta_k)$$

where $\gamma_5 \Gamma_5 = s_5 \Gamma$.
For small masses $m \to 0$ the functions $g$ emphasize the contributions of small eigenvalues. If the eigenvalue density $\rho(m, \eta)$ vanishes at small eigenvalues, then the propagator difference vanishes as well and axial symmetry is restored. The factors with eigenvectors are bounded (the eigenvectors are normalized).

The integral over $x, y$ and sum over $a$ and the other, hidden indices gives the susceptibility. For $\Gamma = 1$ the second term in (25) vanishes due to orthogonality. The first term gives $\delta_{nk}$. The susceptibility difference (the $U_A(1)$ susceptibility) then is

$$\chi(1) - \chi(1^n) = -\frac{4}{V} \sum_{n>0} g(m, \eta_n)^2 \approx \int_0^\infty d\eta \rho(m, \eta) g(m, \eta)^2. \quad (24)$$

for the eigenvalue density $\rho(m, \eta)$ (cf. [15], the discussion in [17] and [5][11][16]). This term vanishes if there is a gap in $\rho(m, \eta)$ or if the density vanishes fast enough$^2$ for $\eta \to 0$. The susceptibilities for the other difference pairs of Table I are also $g$-equivalent.

2. **Isovector vs. Isoscalar**

Isoscalar propagators have also disconnected contributions. For $\Gamma \in \{1, \gamma_k \gamma_j, \gamma_k \gamma_5, \gamma_k, \gamma_k \gamma_5, \gamma_k \gamma_5\}$ they have the form (for the derivation see Appendix B)

$$\sum_{n>0, k>0} 4 g(m, \eta_n) g(m, \eta_k) \psi^{(n)}(x) \Gamma_{sn} \psi^{(n)}(x) \psi^{(k)}(y) \sigma L^{(n)}(x) L^{(k)}(y). \quad (25)$$

We find that if the eigenvalue density at small eigenvalues vanishes, the disconnected term vanishes as well. The isoscalar is $g$-equivalent to the isovector propagators for these $\Gamma$. Combining the relations with those of Sect. III A 1 one obtains further relations between isoscalar pairs $(1, \gamma_5), (i\gamma_k \gamma_j, i\gamma_k \gamma_5)$ and $(\gamma_k \gamma_4, \gamma_k \gamma_5)$. The scalar mesons at high temperature were studied in [6].

**B. $h$-equivalent mesons**

1. **More disconnected terms**

Compared with $g$-equivalence the now discussed type is more subtle with factors $h(m, \eta)$, needing further bounds or eigenmode properties to find propagator agreement. To see this we use the chiral basis of Sect. III B.

The disconnected contributions for propagators with $\Gamma \in \{\gamma_k, \gamma_4, \gamma_k \gamma_5, \gamma_4 \gamma_5\}$ have terms with factors like

$$h(m, \eta_k) h(m, \eta_k) \left(\Gamma^{(n)}(x) \sigma L^{(k)}(y) \sigma R^{(n)}(x)\right), \quad (26)$$

where $\sigma$ is a $2 \times 2$ matrix (i.e., a sub-block of $\Gamma$; for the complete expression see App. [C]). The prefactor again favors low eigenmodes for small $m$. Therefore the disconnected contributions become much smaller if the low modes are suppressed in the generic density.

Even if the low modes are absent, however, the higher modes still contribute to the difference more than in the $g$-equivalent case since $h(m, \eta)$ decreases slower with $\eta$ than $g(m, \eta)$. The quality of the agreement then depends on the matrix elements in (26) and not only on the eigenvalue density. This is discussed in the subsequent section.

If the high modes contribution can be neglected the isoscalar propagator agrees with the isovector propagator for the listed $\Gamma$. Considering the results for the connected propagators this implies also agreement of the isoscalar propagator pairs $(\gamma_k, \gamma_k \gamma_5)$ and $(\gamma_4, \gamma_4 \gamma_5)$.

2. $\Gamma$ vs. $\Gamma \gamma_4$

Finally let us consider the connected propagator pairs for $(\Gamma, \Gamma \gamma_4)$ for $\Gamma \in \{1, \gamma_k, \gamma_k \gamma_5, \gamma_k \gamma_j, \gamma_k \gamma_5\}$; these are central for the CS symmetry. The propagator differences are sums of two types of terms

$$g(m, \eta_n) g(m, \eta_k) \left(\left(L^{(n)}(x) \sigma L^{(k)}(y) \sigma L^{(n)}(y)\right) + (R^{(n)}(x) \sigma R^{(k)}(y) \sigma R^{(n)}(y))\right) \quad (27)$$

and

$$h(m, \eta_n) h(m, \eta_k) \left(\left(R^{(n)}(x) \sigma R^{(k)}(y) \sigma L^{(n)}(y)\right) + (L^{(n)}(x) \sigma L^{(k)}(y) \sigma R^{(n)}(y))\right). \quad (28)$$

The first term becomes negligible if the fermion mass is small and if there is a gap in $\rho(m, \eta)$ at small $\eta$. In the second term, unlike the connected propagators discussed in Sect. III A 1 all four types $R^1 \sigma L, L^1 \sigma R, R^1 \sigma R, L^1 \sigma L$ enter the propagator difference multiplying $h$.

When there are no eigenvalues below some $|\eta| < \eta_0$ or the generic density vanishes fast enough towards $\eta = 0$ the propagator difference is dominated by the terms with $h$. The factors $L^1 \sigma R$, etc., encode the dynamics of QCD. There are a few observations that may shed some light:

$^2$ A behavior $\lim_{m \to 0} \rho(m, \eta) = O(\eta^2)$ is sufficient for the vanishing of the $U_A(1)$ susceptibility [15].
TABLE II. Related meson propagators; For g-equivalent propagators the differences vanish in the massless limit if there are no low lying modes. Further assumptions are necessary for h-equivalence.

- The h- and g-terms of the difference pairs \((1, \gamma_4)\) and \((i\gamma_3, i\gamma_4\gamma_5)\) are identical, as are those for \((\gamma_k, \gamma_k\gamma_4)\) and \((i\gamma_k\gamma_3, i\gamma_k\gamma_4\gamma_5)\). In other words, if the propagator for \(\gamma_k\) and \(\gamma_k\gamma_4\) agree, so do the propagators for \(i\gamma_3\) and \(i\gamma_4\gamma_5\).

- The h-terms vanish for chiral eigenmodes of the form \((R, 0)\) or \((0, L)\) or will be suppressed for almost chiral eigenmodes (where either \(|R| \gg |L|\) or \(|R| \ll |L|\)). However, such behaviour is expected mainly for the low lying modes which are truncated or suppressed anyhow in the situation of relevance here.

- The mesons with \(\Gamma = \gamma_4\) or \(\gamma_4\gamma_5\) have only terms \(R^1L\) and \(L^1R\); now \(R^1\) and \(L\) correspond to the same helicity which cannot add up to zero. The states cannot be physical scalars \([12]\). For this reason we omit these states in Fig. 3.

- There is numerical evidence \([4]\) indicating that the scalar propagators show less agreement than the vector propagators. This is a hint that the vector matrix elements \(\psi^{(n)\dagger}\gamma_j\psi^{(k)}\) are smaller than the scalar ones \(\psi^{(n)\dagger}\psi^{(k)}\).

IV. CONCLUSIONS

Here we studied the rôle of low lying eigenmodes of the Dirac operator in meson propagators. The study is motivated by lattice QCD calculations where it was found that the differences between meson propagators of a large class disappear if the low lying (i.e., close to zero) modes of the Dirac operator are suppressed. The mass degeneracies have been observed when the low modes were truncated explicitly \([3,5,12]\) or dynamically suppressed at
large temperature  

There are two qualitatively different kinds of relations. Those with a weight factor \( g(m, \eta) \) we call \( g \)-equivalent. Meson propagators that are \( g \)-equivalent (Fig.8 and Table I) approach each other for small quark mass, if there is a low-eigenvalue suppression or gap in the generic eigenvalue density. These equivalences, when realized, restore the axial symmetries \( SU(2)_A \) and \( U(1)_A \).

The second type called \( h \)-equivalence needs further constraints in order to provide vanishing propagator differences. The weight factor \( h(m, \eta) \) is also peaked at small \( \eta \) but does not suppress the higher modes as efficient. In that case the quality of agreement depends on the overlap of eigenvectors.

We find:

- The connected (isovector) propagators \( P_c(\Gamma) \) and \( P_c(i\gamma_5) \) for \( \Gamma \in \{1, \gamma_k, \gamma_5, \gamma_k\gamma_j, \gamma_k\gamma_5\} \) differ only by \( g \)-type terms. If there is a low mode suppression the propagators of a pair agree with each other for \( m \to 0 \). The susceptibilities of the connected (isovector) propagators \( P_c(\Gamma) \) inherit the \( g \)-equivalence property.

- For some isoscalar mesons (see Sect. [III A 2]) the propagators’ disconnected contributions are \( g \)-type terms. For these mesons the isoscalar and isovector propagators agree in the massless limit if there is a suppression of low eigenvalues.

- The connected (isovector) propagators \( P_c(\Gamma) \) and \( P_c(\Gamma\gamma_4) \) for \( \Gamma \in \{1, \gamma_k, \gamma_5, \gamma_k\gamma_j, \gamma_k\gamma_5\} \) differ by \( g \)-type and \( h \)-type terms. The \( h \)-terms become small for almost chiral eigenmodes (where either \( |R| \gg |L| \) or \( |R| \ll |L| \)) or small overlap \( \phi^{(n)}\Gamma^\dagger\phi^{(k)} \).

- The propagator difference \( (P_c(\gamma_k) - P_c(\Gamma\gamma_4)) \) differs from \( (P_c(i\gamma_5) - P_c(\Gamma\gamma_5)) \) only by \( g \)-type terms. I.e., if the \( h \)-type contribution vanishes for one pair it also vanishes for the other. Also the propagator difference \( (P_c(1) - P_c(\gamma_4)) \) differs from \( (P_c(i\gamma_5) - P_c(\Gamma\gamma_5)) \) only by \( g \)-type terms.

In summary the axial symmetries between the meson propagators and susceptibilities are recovered for decreasing quark mass upon suppression of low lying eigenmodes in the eigenvalue distribution. A similar behaviour for the observed \( \gamma_4 \) symmetry requires in addition small overlap of the higher eigenmodes.

The emerging agreement between the meson propagators explains numerical lattice QCD results for meson mass degeneracies. Based on the meson mass pattern the symmetries CS and \( SU(4) \) were conjectured [12]. These may have far-reaching consequences [22].

### ACKNOWLEDGMENTS

I profited much from discussions with Christof Gattringer and Vasily Sazonov. Many thanks go to Leonid Glozman for numerous discussions, for reading the manuscript, and for his persistence.

### Appendix A: \( P_c(\Gamma, x, y) - P_c(\Gamma\gamma_5, x, y) \)

The connected propagator \( P_c(\Gamma) \) for \( \Gamma \) is written in terms of the spectral representation of the quark propagators:

\[
P_c(\Gamma) = s_T \sum_{n,k} f_n f_k \psi^{(k)}_{x,a} \Gamma_{a,b} \psi^{(n)}_{x,b} \psi^{(n)}_{y,c} \Gamma_{c,d} \psi^{(k)}_{y,d},
\]

with \( s_T \) defined in Sect. [III] and Table I and summation over paired indices is implied. We use the abbreviation

\[
f_n = \frac{1}{\eta_n + 1}
\]

with \( \eta_{-n} = -\eta_n \). There are no exact zero modes by assumption. We rewrite the sum like

\[
s_T \sum_{n,k=0} f_n f_k \psi^{(k)}_{x,a} \Gamma_{a,b} \psi^{(n)}_{x,b} \psi^{(n)}_{y,c} \Gamma_{c,d} \psi^{(k)}_{y,d}
\]

\[
+ f_n f_k \psi^{(n)}_{x,a} \Gamma_{a,b} \psi^{(k)}_{x,b} \psi^{(n)}_{y,c} \Gamma_{c,d} \psi^{(k)}_{y,d}
\]

\[
+ f_n f_k \psi^{(k)}_{x,a} \Gamma_{a,b} \psi^{(n)}_{x,b} \psi^{(n)}_{y,c} \Gamma_{c,d} \psi^{(k)}_{y,d}
\]

\[
+ f_n \psi_{x,a} \Gamma_{a,b} \psi_{x,b} \psi_{y,c} \Gamma_{c,d} \psi_{y,d}
\]

\[
= s_T \sum_{n,k=0} \left[ f_n f_k + f_{n+k} \right]
\]

\[
\psi^{(k)}_{x,a} \Gamma_{a,b} \psi^{(n)}_{x,b} \psi^{(n)}_{y,c} \Gamma_{c,d} \psi^{(k)}_{y,d}
\]

\[
+ f_{n+k} \psi_{x,a} \Gamma_{a,b} \psi_{x,b} \psi_{y,c} \Gamma_{c,d} \psi_{y,d}
\]

\[
= s_T \sum_{n,k=0} \left[ -2g(m, \eta_n)g(m, \eta_k) + 2h(m, \eta_n)h(m, \eta_k) \right]
\]

\[
\psi^{(k)}_{x,a} \Gamma_{a,b} \psi^{(n)}_{x,b} \psi^{(n)}_{y,c} \Gamma_{c,d} \psi^{(k)}_{y,d}
\]

\[
+ \left( -2g(m, \eta_n)g(m, \eta_k) - 2h(m, \eta_n)h(m, \eta_k) \right)
\]

\[
\psi^{(k)}_{x,a} \Gamma_{a,b} \psi^{(n)}_{x,b} \psi^{(n)}_{y,c} \Gamma_{c,d} \psi^{(k)}_{y,d}
\]

(3)

Here we used relations like [20] and [22] and

\[
f_n f_k + f_{n+k} = -2g(m, \eta_n)g(m, \eta_k) + 2h(m, \eta_n)h(m, \eta_k)
\]

\[
f_{n+k} + f_{n+k} = -2g(m, \eta_n)g(m, \eta_k) - 2h(m, \eta_n)h(m, \eta_k)
\]

(4)
The propagator is

\[ P_c(i \Gamma_{5}) = i^2 s_5 \Gamma_{5} \sum_{n>0,k>0} \left[ (-2g(m, n)g(m, n_k) + 2h(m, n)h(m, n_k)) \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right. \\
\left. + (-2g(m, n)g(m, n_k) - 2h(m, n)h(m, n_k)) \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right] \\
= -s_5 \sum_{n>0,k>0} \left[ (-2g(m, n)g(m, n_k) + 2h(m, n)h(m, n_k)) \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right. \\
\left. + (-2g(m, n)g(m, n_k) - 2h(m, n)h(m, n_k)) \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right] \]  

(A5)

where we replaced in [A3] \( s_5 \) by \( s_5 \Gamma_{5} \) and \( \Gamma \) by \( \Gamma_{5} \) and utilized \([20]\).

The difference between the propagators becomes in all cases

\[ P_c(\Gamma) - P_c(\Gamma_{5}) = -4 \sum_{n>0,k>0} g(m, n)g(m, n_k) \]

\[ \left[ \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right. \\
\left. + \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right] \]  

(A7)

**Appendix B: Disconnected terms**

These terms are responsible for the difference between isovector and isoscalar propagators and have the form

\[ P_d(\Gamma) = -s_5 \left[ \sum_k f_k(\Gamma)_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \right] \left[ \sum_n f_n(\Gamma)_{y,c}^{(n)}(\Gamma)_{c,d}^{(n)} \right] \]  

(B1)

Rewriting the first sum gives

\[ - \sum_{k>0} [f_k(\Gamma)_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} + f_{-k}(\Gamma)_{x,a}^{(-k)}(\Gamma)_{x,a}^{(-k)}] \]

\[ = \sum_{k>0} [f_k(\Gamma)_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} + f_{-k}s_5(\Gamma)_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)}] \]

\[ = - \sum_{k>0} [f_k + s_5f_{-k}](\Gamma)_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \]  

(B2)

where we used \([20]\) in the 2nd step. Equivalent derivation for the 2nd sum leads to

\[ P_d(\Gamma) = -s_5 \sum_{k>0,n>0} (f_k + s_5f_{-k})(f_n + s_5f_{-n}) \]

\[ \times \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(n)} \]  

(B3)

For \( \Gamma \in \{1, \gamma_k\gamma_j, \gamma_k\gamma_4, i\gamma_5, i\gamma_k\gamma_5, i\gamma_k\gamma_4\gamma_5\} \) we find \( s_5 = 1 \) and

\[ (f_k + f_{-k})(f_n + f_{-n}) = -4g(m, n)g(m, n_k) \]  

(B4)

giving \([25]\).

For \( \Gamma \in \{\gamma_k, \gamma_k\gamma_5, \gamma_k\gamma_4\gamma_5\} \) we find \( s_5 = -1 \) and

\[ (f_k - f_{-k})(f_n - f_{-n}) = 4h(m, n)h(m, n_k) \]  

(B5)

which is discussed below in App. \([C]\).

**Appendix C: More disconnected terms**

This concerns the disconnected terms \([B5]\) in Sect. \([III\, B\, 1]\). We consider the disconnected contribution to propagators for \( \Gamma \in \{\gamma_k, \gamma_4, \gamma_k\gamma_5, \gamma_k\gamma_4\gamma_5\} \) discussed at the end of App. \([B]\). Since the functions \( h(m, n) \) have slower decay towards larger \( n \) we have a closer look at the matrix elements. In the chiral basis of \([13]\) the matrices \( \Gamma \) have the form

\[ \begin{pmatrix} 0 & \sigma \\ -\sigma & 0 \end{pmatrix} \]  

(C1)

Then in all cases we find the form (\( \sigma \) depends on the actual \( \Gamma \) and is proportional to a Pauli matrix)

\[ P_d(\Gamma) = 4s_5 \sum_{k>0,n>0} h(m, n)h(m, n_k) \]

\[ \times (R^{(n)}(x) \sigma L^{(n)}(x) + L^{(n)}(x) \sigma R^{(n)}(x)) \]

\[ \times (R^{(k)}(y) \sigma L^{(k)}(y) + L^{(k)}(y) \sigma R^{(k)}(y)) \]  

In all terms upper components couple to lower ones. If the overlap is small (e.g., the eigenmodes are close to chiral) then this contribution is small and the isovector and isoscalar propagators for that \( \Gamma \) are similar.

**Appendix D: \( P_c(\Gamma) - P_c(\Gamma_4) \)**

Also the connected propagator differences between these pairs need additional assumptions like those of App. \([C]\). We inspect pairs (\( \Gamma, \Gamma_4 \)) for \( \Gamma \in \{1, \gamma_k, \gamma_5, \gamma_k\gamma_5, \gamma_k\gamma_4\gamma_5\} \).

Using \([A3]\) we get

\[ P_c(\Gamma) - P_c(\Gamma_4) = \sum_{n>0,k>0} \left[ (-2g(m, n)g(m, n_k) + 2h(m, n)h(m, n_k)) \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right. \\
\left. - s_5(\Gamma)_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right. \\
\left. + (-2g(m, n)g(m, n_k) - 2h(m, n)h(m, n_k)) \psi_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right. \\
\left. - s_5(\Gamma)_{x,a}^{(k)}(\Gamma)_{x,a}^{(k)} \psi_{y,c}^{(n)}(\Gamma)_{c,d}^{(k)} \right] \]  

(D1)
We change to formulation (13); the matrix pair $\Gamma$ and $\Gamma_{\Gamma_4}$ have a form like, e.g.,

\[
\begin{pmatrix}
\sigma & 0 \\
0 & \sigma
\end{pmatrix}
\quad \text{and} \quad
\begin{pmatrix}
0 & \sigma \\
\sigma & 0
\end{pmatrix}.
\]

(D2)

As example we take $\Gamma = 1$ and $\Gamma_{\Gamma_4} = \Gamma_4$ where $s_{\Gamma} = s_{\Gamma_4} = 1$. (The other combinations give similar results, differing only in some signs.) Then (D1) becomes

\[
4 \sum_{n>0, k>0} \left[ g(m, \eta_k) g(m, \eta_n) \left( -L^{(n)}(x) L^{(k)}(x) L^{(k)}(y) L^{(n)}(y) \\
+ R^{(n)}(x) L^{(k)}(x) L^{(k)}(y) R^{(n)}(y) \\
+ R^{(n)}(x) R^{(k)}(x) R^{(k)}(y) L^{(n)}(y) \\
- R^{(n)}(x) R^{(k)}(x) R^{(k)}(y) R^{(n)}(y) \right) \\
+ h(m, \eta_k) h(m, \eta_n) \\
( -L^{(n)}(x) R^{(k)}(x) L^{(k)}(y) R^{(n)}(y) \\
- R^{(n)}(x) L^{(k)}(x) R^{(k)}(y) L^{(n)}(y) \\
+ R^{(n)}(x) R^{(k)}(x) L^{(k)}(y) L^{(n)}(y) \\
+ L^{(n)}(x) R^{(k)}(x) R^{(k)}(y) R^{(n)}(y) \right) \right].
\]

(D3)

Again we find a term with $g(m, \eta_k) g(m, \eta_n)$ which vanishes if the small modes disappear. The term with $h(m, \eta_k) h(m, \eta_n)$ has significant contributions from low modes which disappear with them. It decays, however, slower for increasing $\eta$. If the modes above the gap are close to chiral, this term becomes small as well. In that case we are left with the $g$-type terms and the propagators are $g$-equivalent.
