INTRODUCTION

In recent years, Internet has been used worldwide and has become an essential tool, especially for younger age groups. It is important to explore Internet-use habits and any influence they can have on users. Although a term accurately describing the clinical features of Internet-related behavioral problems is not yet available, it can generally be defined as: “Use of Internet that cannot be controlled and that produces psychological, social, academic, and/or work problems”; and it has been described by various terms such as Internet addiction, compulsive Internet use, problematic Internet use, and pathological Internet use (PIU) [1,2]. Despite the inconsistent use of the term in the literature, the fact that PIU produces negative consequences on users is well-documented. PIU is most relevant to adolescents and young adults. According to 2014 statistics on Internet addiction in South Korea, the highest risk group were adolescents (12.5%), while adults were second (5.8%) [3]. Park et al. [4] reported that adolescents in South Korea who met the criteria for PIU were at significantly increased risk for depression and suicidal ideation. For adults, PIU can result in worse consequences than in adolescents. Recent studies in the United States and Hong Kong have explored the relationships between PIU and family
relationships and sleep problems among college students [5,6]. In South Korea, Kim et al. [7] reported an increased risk of depression and anxiety in the Internet addiction group aged 19 to 39 years. Since college students are especially vulnerable to developing PIU, we evaluated the prevalence of PIU in college students in the Jeju area, and its relationship to psychiatric symptoms including depression, anxiety, and suicidality.

1. Participants

In this study, the researchers sent letters, including a statement explaining the purpose of the study, to colleges located in the Jeju Special Self-Governing Province, South Korea. Four colleges agreed with the purpose of the study, and the researchers received written informed consent from a total of 1,416 college students aged 18 years or older, who completed a self-administered questionnaire. The study was performed with the assistance of 8 research assistants, including social workers and psychiatric nurses. They explained to the participants the purpose of the survey and provided directions for participants to answer the survey questionnaires, which included several self-report screening instruments. This study was approved by the Institutional Review Board of Jeju National University Hospital (IRB No. JE-JUNUH 2018-10-009-001). A total of 26 subjects were excluded because their responses were incomplete, thus leaving a total of 1,390 subjects for the final analysis.

2. Assessment

A self-report questionnaire was used to obtain information regarding various sociodemographic, trauma-related, and clinical symptom-related variables. The variables include age, sex, parental marital status, self-reported socioeconomic status (SES), school records, satisfaction with school life and familial relationships, a history of childhood adversity (including physical or sexual abuse by other people, and school bullying), and previous history of psychiatric disorders. Body mass index (BMI = weight [kg]/square of height [m²]) was calculated based on self-reported weight and height, and subjects with BMI ≥25 were classified as overweight or obese [8]. We administered the Alcohol Use Disorder Identification Test-Alcohol Consumption instrument to assess the severity of alcohol use problems. A cutoff score of 8 was used in this study to represent significant alcohol use problems [9].

To screen for PIU, we used the Self-Report Scale for Measuring Behavioral Symptoms of Adults’ PIU. This scale is a screening tool for Internet addiction among adults composed of 20 items. It has high internal consistency (Cronbach’s α=0.87) and consists of four factors including virtual reality, distraction and mood alteration, tolerance and preoccupation, and feeling guilty for Internet use. A cutoff score of 43 was adopted to detect PIU in this study [10].

To obtain information regarding depression, anxiety, and suicidality, we administered the Patient Health Questionnaire-9 (PHQ-9), the Generalized Anxiety Disorder Screener (GAD-7), and the Suicide module of the Mini International Neuropsychiatric Interview (M.I.N.I.). Depression was identified using the PHQ-9, which is a reliable screening tool for measuring depressive symptoms and severity over the past 2 weeks. The PHQ-9 is composed of nine items rated from 0 (not at all) to 3 (having the symptoms nearly every day), and the scores for each item are summed to produce a total depression severity score (range: 0-27) [11]. The Korean version of the PHQ-9 has high internal consistency (Cronbach’s α=0.831) [12], and participants in this study were identified as having depression if their total score of the PHQ-9 score was ≥10 [11,12]. The GAD-7 is a one-dimensional instrument designed to detect anxiety symptoms. The item scores ranged from 0 (not at all) to 3 (nearly every day), resulting in a sum score range from 0 to 21. A cutoff score of 10 was adopted to detect any significant anxiety symptoms in this study [13]. The Suicide module of the M.I.N.I., which was used to evaluate suicide risk, includes six questions that assess suicidal ideation within the past month (“Have you thought you would be better off dead or wished you were dead?”; “Have you wanted to harm yourself?”; and “Have you thought about suicide?”), suicide plans within the past month (“Did you have a suicide plan?”), suicide attempts within the past month (“Have you attempted suicide?”), and lifetime suicide attempts (“In your lifetime, have you ever attempted suicide?”). The score for each answer was weighted according to its importance in assessing suicide risk [14,15].
3. Statistical analysis

The Pearson chi-square test and independent t-test were used to compare the proportions and means of the independent variables versus dependent variables. For the correlation analyses, univariate associations were investigated between independent variables and PIU. Factors potentially associated with PIU on univariate analyses were then entered simultaneously into a logistic regression model to assess independence. Odds ratios (ORs) and 95% confidence intervals (CIs) were derived from a series of logistic regression analyses. All statistical analyses were performed using IBM SPSS Statistics for Windows, Version 25.0 (IBM Co., Armonk, NY, USA), and statistical significance was determined using an alpha level of 0.05 (two-tailed tests).

Table 1. Comparisons of characteristics among subjects with and without PIU among college students

| Variable                      | Normal users (n=1,156) | PIUs (n=234) | p-value |
|-------------------------------|------------------------|--------------|---------|
| Age (y)                       |                        |              |         |
| ≤ 20                          | 591 (51.1)             | 130 (55.6)   | 0.417   |
| 21–24                         | 490 (42.4)             | 92 (39.3)    |         |
| ≥25                           | 75 (6.5)               | 12 (5.1)     |         |
| Sex                           |                        |              | 0.069   |
| Male                          | 484 (41.9)             | 83 (35.5)    |         |
| Female                        | 672 (58.1)             | 151 (64.5)   |         |
| Parental marital status       |                        |              | 0.365   |
| Married                       | 894 (77.5)             | 190 (81.2)   |         |
| Divorced/separated            | 194 (16.8)             | 35 (15.0)    |         |
| Widowed                       | 66 (5.7)               | 9 (3.8)      |         |
| Self-reported SES             |                        |              | 0.620   |
| High                          | 229 (19.8)             | 40 (17.1)    |         |
| Middle                        | 794 (68.7)             | 164 (70.1)   |         |
| Low                           | 132 (11.4)             | 29 (12.4)    |         |
| School records                |                        |              | 0.054   |
| Above average                 | 337 (29.2)             | 72 (30.8)    |         |
| Average                       | 633 (54.8)             | 111 (47.4)   |         |
| Below average                 | 186 (16.1)             | 51 (21.8)    |         |
| Satisfaction with school life |                        |              | <0.001* |
| Very unsatisfied              | 21 (1.8)               | 6 (2.6)      |         |
| Unsatisfied                   | 87 (7.5)               | 39 (16.7)    |         |
| Average                       | 512 (44.3)             | 107 (45.7)   |         |
| Satisfied                     | 452 (39.1)             | 76 (32.5)    |         |
| Very satisfied                | 84 (7.3)               | 6 (2.6)      |         |
| Family emotional support      |                        |              | 0.001*  |
| No support                    | 21 (1.8)               | 8 (3.4)      |         |
| Frequent support              | 298 (25.9)             | 86 (36.8)    |         |
| Sufficient support            | 832 (72.3)             | 140 (59.8)   |         |
| History of physical abuse     | 120 (10.4)             | 44 (18.8)    | <0.001* |
| History of sexual abuse       | 17 (1.5)               | 7 (3.0)      | 0.162   |
| History of school bullying    | 145 (12.6)             | 48 (20.6)    | 0.001*  |
| Previous psychiatric history  | 50 (4.3)               | 17 (7.4)     | 0.052   |
| Overweight or obesity         | 208 (21.1)             | 43 (20.5)    | 0.831   |
| Problematic alcohol use       | 352 (30.5)             | 78 (33.6)    | 0.353   |

Values are presented as number (%) and different subtotal because of missing.
PIU, pathological Internet use; SES, socioeconomic status.
*Statistically significant difference.
**RESULTS**

Of the 1,390 participants, 567 males (40.8%) and 823 females (59.2%) were included; 51.9% were under the age of 20, 41.9% were between the ages of 21 and 24 years, and the remaining (6.2%) were aged 25 years or older. A total of 164 participants (11.8%) had histories of physical abuse, and 193 participants (13.9%) had histories of school bullying. Previous psychiatric histories were reported by a total of 67 participants (4.8%).

We found that 16.8% of all participants were PIUs, and histories of childhood adversity were significantly related to PIU; the p-value for a history of physical abuse was <0.001, and that of a history of school bullying was 0.001. Moreover, it is important to note that there were significant differences between normal users and PIUs in terms of satisfaction with school life (p<0.001) and family emotional support (p=0.001); PIUs reported having a more unsatisfactory school life (very unsatisfied=2.6%) and less family emotional support (no support=3.4%) than normal users (very unsatisfied=1.8%, no support=1.8%). Age, sex, parental marital status, self-reported SES, overweight or obesity, and problematic alcohol use were not related to PIU (Table 1).

The PHQ-9, the GAD-7, and the M.I.N.I. suicidal risk scores were significantly higher in PIUs than normal users. A total of 153 college students (11.0%) had positive PHQ-9 scores, suggestive of depression. Likewise, GAD-7 scores suggesting anxiety symptoms were positive in a total of 82 college students (5.9%). Univariate analysis revealed significant associations between depression and PIU (p<0.001), and anxiety and PIU (p<0.001). Moreover, the prevalence of lifetime suicidal behaviors (suicidal ideation, plan, and attempt) was also significantly associated with PIU (p<0.001; Table 2).

Table 2 shows multivariate associations between the independent variables and PIU. After adjusting for age, sex, and previous psychiatric history, the results showed that unsatisfactory school life (OR, 2.56; 95% CI, 1.06-6.15; p=0.036), presence of depression (OR, 1.67; 95% CI, 1.03-2.71; p=0.036), and presence of anxiety symptoms (OR, 3.36; 95% CI, 1.91-5.93; p<0.001) were significantly related to PIU.

**DISCUSSION**

The results of this study enhance our understanding of the relationship between PIU and psychological symptoms in college students. Our results showed that among college students in the Jeju area, 16.8% were engaged in PIU and it was significantly associated with various factors including family environment and psychological states. We found that this prevalence is higher than that of previous studies performed with young adults. Among Korean adults aged 18 to 64 years, the prevalence of PIU was 9.3% [16], and in a Spanish study 6.4% of college students engaged in PIU [17]. Similarly, the prevalence of PIU among Chinese college students was 10.2% [18], and among the 3.1% of Slovenian adult Internet users who are at risk of becoming problematic Internet users, 11% of them belonged to the age group.

### Table 2. Comparisons of depression, anxiety, and suicidality among subjects with and without PIU among college students

| Variable                              | Normal users (n=1,156) | PIUs (n=234) | p-value |
|---------------------------------------|------------------------|--------------|---------|
| Depression                            |                        |              |         |
| PHQ-9 positive                        | 95 (8.2)               | 58 (24.8)    | <0.001* |
| PHQ-9 total score                     | 3.51±3.94              | 6.94±5.34    | <0.001* |
| Anxiety                               |                        |              |         |
| GAD-7 positive                        | 41 (3.6)               | 41 (17.5)    | <0.001* |
| GAD-7 total score                     | 2.42±3.21              | 5.12±4.66    | <0.001* |
| Suicidality                           |                        |              |         |
| Lifetime suicidal behaviors, yes      | 210 (18.2)             | 92 (39.3)    | <0.001* |
| M.I.N.I. suicide risk score           | 1.27±3.71              | 3.00±4.84    | <0.001* |

*Statistically significant difference.
from 20 to 24 years [19]. However, it is difficult to compare our results with those of other prevalence studies because of the application of different measuring tools, regional characteristics, and cultural differences.

Similar to other studies, we found that college students engaged in PIU showed significant associations with childhood adversity and a lack of family emotional support. According to previous studies with adolescents, victims of bullying including cyber-bullying were more likely to develop PIU than peers who were not involved in bullying, and adolescents having poor communication with their parents were prone to PIU [20-22]. A history of sexual abuse also predicted PIU in adolescents [23]. In the case of college students, there are some reports that less-caring parents or conflicts with parents are related to PIU, and suggest that individuals who engaged in PIU may seek social support through the Internet by making online relationships [5,19]. Given that the target population of numerous existing studies on PIU and its risk factors are adolescents, our findings warrant further investigations to young adults who engage in PIU and possible temporal relationships of associated factors and PIU.

The present study showed that college students who engaged in PIU also manifested a significant risk of psychiatric symptoms such as depression and anxiety. This result is consistent with previous findings [1,4,6,7,17,19,23,24]. Kim et al. [7] showed an increased risk of depression and anxiety in Korean adults aged 19 to 49 years who are addicted to the Internet. Yang et al. [19] suggested that individuals engaged in PIU may use the Internet to escape from stressful events and to cope with real-life difficulties. They might seek online relationships to relieve or hide their negative feelings and anxiety originating from their inadequate relationships in reality [1]. Many studies have also stated that PIU increases the risk of psychiatric disorders; more severe PIU, results in worse psychiatric symptoms [4,6,19]. Kim et al. [7] explained the role of internet addiction in developing depression and anxiety. First, Internet addiction and PIU can cause complications with family and friends, since most of their time is devoted to cyberspace. Second, the withdrawal symptoms of Internet addiction is comparable to substance-use disorders and lastly, addicts may not be aware of their excessive use because their access to devices are relatively free and flexible [7]. Individuals engaged in PIU also tend to have a history of psychiatric disorders, such as depression, anxiety, bipolar disorder, and impulse control disorder, and these disorders could predict PIU [23-25]. Psychiatric symptoms are not only affected by PIU but can also result in development of PIU. Thus, it is impor-

### Table 3. Factors associated PIU among college students

| Variable                                      | Normal versus PIUs | OR (95% CI)       | p-value     |
|-----------------------------------------------|--------------------|-------------------|-------------|
| Sex (reference: male)                        |                    |                   |             |

*Statistically significant difference.
tant to observe interactive relationships between psychiatric disorders and PIU.

Consistent with previous studies [4,17,26], our finding also showed that college students engaged in PIU had higher suicidality than normal Internet users. Regarding depression and anxiety, one study with Korean adolescents showed that PIU could predict suicidal ideation, and suicidal ideation could also predict PIU [4]. In addition, in individuals engaged in PIU, suicidal behaviors such as suicidal ideation, plans, and attempts were higher than in normal users [17,26]. Many studies showed that suicidality often occurs along with other psychiatric disorders in individuals engaged in PIU; these findings suggest that these factors are all interconnected and could possibly have reinforcing interactions.

This study has the following limitations. First, it is difficult to explore the causal relationship between PIU and related factors, since this is a cross-sectional study. A prospective study is required to classify PIU as a predictive factor for depression, anxiety, and suicidality. Second, measures of PIU and psychiatric symptoms were based on self-report rather than clinical evaluation. Lastly, this study was conducted in college students in a specific area, so it is difficult to generalize the research results.

CONCLUSIONS

The present study observed factors associated with college students who engage in PIU. Most importantly, individuals engaged in PIU had significant risks for depression, anxiety, and suicidality, and these psychiatric problems and PIU seemed to have an effect in both directions. Because the comorbidity rate is high between PIU and many psychiatric symptoms, prospective studies based on different sampling groups will enhance our understanding of the mechanisms that influence PIU and allow us to investigate preventive intervention strategies.
