Abstract

The ongoing searches for Higgs-boson signals in data taken at the CERN LHC
and the Fermilab Tevatron crucially rely on the decay channels $H \rightarrow Z\ell\ell$ and
$H \rightarrow W\ell\nu$. We present a precision study of the partial widths of these decay
channels including the full one-loop electroweak corrections and the dominant con-
tributions at two and three loops, of $O(G_F^2m_t^4)$, $O(G_Fm_t^2\alpha_s)$, and $O(G_Fm_t^2\alpha_s^2)$. Since the invariant mass of the off-shell intermediate boson is relatively low in the
mass window $115 \text{ GeV} < m_H < 129 \text{ GeV}$ of current interest, lepton mass effects are
relevant, especially for the $\tau$ lepton.

1 Introduction

The ATLAS and CMS collaborations at the \(pp\) collider LHC are presently closing in on the Higgs boson of the standard model (SM). The combined ATLAS results, based on the full data set of up to 4.9 \(fb^{-1}\) recorded during the 2011 operation at the center-of-mass energy \(\sqrt{s} = 7\) TeV, excluded the Higgs-boson mass \((m_H)\) windows from 110.0 GeV to 117.5 GeV, from 118.5 GeV to 122.5 GeV, and from 129 GeV to 539 GeV at the 95% confidence level (C.L.) [1]. A small excess of signal events over the estimated background was observed around \(m_H = 126\) GeV with a local significance of 2.5 standard deviations \((\sigma)\). The CMS Collaboration excluded the \(m_H\) window from 127.5 GeV to 600 GeV at 95% C.L. exploiting approximately 5 \(fb^{-1}\) of data at \(\sqrt{s} = 7\) TeV [2]. They observed some excess in the \(m_H\) window from 115 GeV to 128 GeV, with a maximum local significance of 2.8 \(\sigma\) at \(m_H = 125\) GeV.

The CDF and D0 collaborations at the \(p\bar{p}\) collider Tevatron jointly excluded the \(m_H\) windows from 100 GeV to 106 GeV and from 141 GeV to 184 GeV at 95% C.L. by analyzing a luminosity of up to 10 \(fb^{-1}\) collected at \(\sqrt{s} = 1.96\) TeV [3]. They observed an excess of signal over background in the \(m_H\) window from 115 GeV to 135 GeV, with a local significance of 2.2 \(\sigma\) at \(m_H = 120\) GeV. The ALEPH, DELPHI, L3, and OPAL collaborations at the CERN e\(^+\)e\(^-\) collider LEP established a \(m_H\) lower bound of 114.4 GeV at 95% C.L. using a total of 2.461 \(fb^{-1}\) data collected at 189 GeV < \(\sqrt{s} < 209\) GeV [4].

The searches at the LHC for the SM Higgs boson in the low-\(m_H\) region mainly rely on its decay channels \(H \to \gamma\gamma\) [5,6], \(H \to ZZ^* \to \ell^+\ell^-\ell'^+\ell'^-\) [7,8], \(H \to W^+W^-*, W^+W^- \to \ell^+\nu\ell'^-\nu\) [9,10], where off-mass-shell particles are marked by asterisks and \(\ell, \ell' = e, \mu\). Decays of lesser significance include \(H \to \tau^+\tau^-\) [11] and, in \(W^\pm H\) and \(ZH\) associated production with subsequent \(W^\pm \to \ell^\pm\nu\) and \(Z \to \ell^+\ell^-\) decays, \(H \to b\bar{b}\) [12]. In the following, we briefly review the state of the art regarding the theoretical predictions for the respective partial decay widths. Comprehensive reviews of our theoretical knowledge of the SM Higgs boson may be found in Refs. [13,14] and references cited therein.

As for the partial decay width \(\Gamma(H \to \gamma\gamma)\), the lowest-order result was first obtained in Ref. [15]. The two-loop \(\mathcal{O}(\alpha_s)\) [16] and three-loop \(\mathcal{O}(\alpha_s^2)\) [17] QCD corrections are available. As for the two-loop \(\mathcal{O}(\alpha)\) correction, the contributions induced by light [18] and heavy fermions [19,20] as well as the residual ones [21] are known.

As for the partial decay width \(\Gamma(H \to b\bar{b})\), the one-loop \(\mathcal{O}(\alpha_s)\) [22] and \(\mathcal{O}(\alpha)\) [23,24] corrections have been known for a long time. As for the two-loop \(\mathcal{O}(\alpha^2)\) correction, the leading [25] and next-to-leading [26] terms of the expansion in \(m_t^2/m_H^2\) of the diagrams without top quarks are known. The diagrams containing a top quark can be divided into two classes: diagrams containing gluon self-energy insertions, which are exactly known [27], and double-triangle diagrams, for which the four leading terms of the expansion in \(m_t^2/m_H^2\) are known [28]. The \(m_b\)-independent terms of the two-loop \(\mathcal{O}(\alpha^2)\) and \(\mathcal{O}(\alpha\alpha_s)\) corrections may be obtained from the analogous \(\mathcal{O}(\alpha_s^2)\) one [25] by adjusting coupling constants and color factors [29]. As for the two-loop correction of order \(\mathcal{O}(x_t\alpha_s)\), where \(x_t = G_Fm_t^2/(8\pi^2\sqrt{2})\) parametrizes leading power corrections of top-quark origin, the universal part, which appears for any Higgs-boson decay to a fermion pair, was extracted from.
the full $\mathcal{O}(\alpha\alpha_s)$ result \[30\] and the nonuniversal one, which arises because bottom is the isopartner of top, using a low-energy theorem \[31\]. As for the two-loop $\mathcal{O}(x_t^2)$ correction, the universal \[19,32\] and nonuniversal \[32\] parts are both available. The $\mathcal{O}(G^2_F m_H^4)$ term \[33\], which is universal, dominates the electroweak two-loop correction in the large-$m_H$ regime. The three-loop $\mathcal{O}(\alpha^3_t)$ correction without top-quark contribution was calculated in the massless limit \[34\]. The correction induced by the top quark was subsequently found using an appropriate effective field theory \[35\]. As for the three-loop $\mathcal{O}(x_t\alpha^2_s)$ correction, the universal \[36\] and nonuniversal \[37\] parts are both known. The four-loop $\mathcal{O}(\alpha^4_t)$ correction without top-quark contribution was calculated in the massless limit \[38\]. The residual theoretical uncertainty in the prediction of $\Gamma(H \to b\bar{b})$ was assessed in Ref. \[39\].

As for the partial decay width $\Gamma(H \to \tau^+\tau^-)$, we know the full one-loop $\mathcal{O}(\alpha)$ \[23,41\] and two-loop $\mathcal{O}(\alpha\alpha_s)$ \[30\] corrections as well as the dominant terms of $\mathcal{O}(x_t^2)$ \[19\] and $\mathcal{O}(G^2_F m_H^4)$ \[33\] at two loops, and the one of $\mathcal{O}(x_t\alpha_s^2)$ \[30\] at three loops.

The decays of the Higgs boson to two pairs of light fermions proceed almost exclusively via $W^+W^-$ or $Z^+Z^-$ pairs, the contributions involving the Yukawa couplings of the produced fermions being greatly suppressed, as will be explicitly demonstrated for $H \to ZZ$ and $H \to W^+W^-$ in Sec. 3. If the value of $m_H$ is large enough to allow for one or both intermediate bosons to be on mass shell, then such kinematic configurations will be extremely favored due to the resonating propagators \[40\]. In this case, it is natural to employ the narrow-width approximation, which implies that the resonating intermediate bosons are treated as real particles and their subsequent decays are accounted for by multiplication with the appropriate branching fractions. Such a procedure is also routinely employed when the cross section of a complete scattering process involving the unstable Higgs boson is factorized into the cross section of the Higgs-boson production mechanism and the branching fraction of the Higgs-boson decay channel. In the case of Higgs-boson decays to two light-fermion pairs, this has the advantage that the branching fractions $B(Z \to f\bar{f})$ and $B(W^\pm \to f\bar{f})$ may be taken to be the experimentally measured values, which naturally contain all radiative corrections. As for the partial decay widths $\Gamma(H \to W^+W^-)$ and $\Gamma(H \to ZZ)$, which presuppose that $m_H > 2m_V$ with $V=W,Z$, the full one-loop $\mathcal{O}(\alpha)$ corrections \[23,41,42,43\], also including the subsequent decays into massless-fermion pairs for off-shell $V$ bosons \[14\], the dominant two-loop terms of $\mathcal{O}(x_t\alpha_s)$ \[45,46\], $\mathcal{O}(x_t^2)$ \[19\], and $\mathcal{O}(G^2_F m_H^4)$ \[47\], and the three-loop term of $\mathcal{O}(x_t\alpha_s^2)$ \[36\] are available. In Ref. \[14\], the $\mathcal{O}(G^2_F m_H^4)$ corrections \[47\], which are only relevant for $m_H \gg 2m_V$, and certain higher-order effects due to photonic final-state radiation off charged leptons, which are not logarithmically enhanced for the integrated partial decay widths, were also included.

The purpose of this paper is to present a precision study of the partial decay widths $\Gamma(H \to W^\pm f\bar{f})$ and $\Gamma(H \to Z f\bar{f})$, appropriate for the mass window $m_V < m_H < 2m_V$ of topical interest, retaining the masses of the produced fermions and including the full one-loop corrections and the dominant higher-order terms. In the case of $H \to Z f\bar{f}$ with massless final-state fermions, the one-loop weak correction may be obtained \[13\] by crossing symmetry from the corresponding analysis of $e^+e^- \to ZH$ \[48,49\]. Here, we redo this calculation for massive final-state fermions and incorporate the $\mathcal{O}(x_t^2)$, $\mathcal{O}(x_t\alpha_s)$, and
\( \mathcal{O}(x_t \alpha_s^2) \) terms. We also perform the analogous analysis for \( H \rightarrow W^+ f \bar{f} \). In fact, the numerical analyses for \( H \rightarrow Z \tau^+ \tau^- \) and \( H \rightarrow W^+ \tau^- \bar{\tau} \) in Sec. 2 will reveal that the finite \( \tau \)-lepton mass effects may exceed the radiative corrections in size in the low-\( m_H \) window that is not excluded experimentally. Both channels are bound to be exploited for the search of a low-\( m_H \) Higgs boson and/or the study of its properties in the long run. The \( H \rightarrow \ell^+ \ell^- \tau^+ \tau^- \) channel is already being used by the CMS Collaboration in the high-\( m_H \) range [50].

This paper is organized as follows. In Sec. 2, we expose the structure of our analytical results and list an appropriate selection of our formulas. In Sec. 3, we present our numerical analysis for the \( H \rightarrow Z \ell^+ \ell^- \) and \( H \rightarrow W^+ \ell^- \nu_\ell \) decay channels, which are relevant for the ongoing searches for Higgs-boson signals in data taken at the LHC and the Tevatron. In Sec. 4, we summarize our conclusions.

2 Analytic results

We now present our analytic results. We work in the on-mass-shell renormalization scheme implemented with Fermi’s constant \( G_F \), instead of Sommerfeld’s fine-structure constant \( \alpha \), and use the shorthand notations \( h = m_H^2 \), \( w = m_W^2 \), \( z = m_Z^2 \), and \( c_w^2 = 1 - s_w^2 = w/z \).

2.1 \( H \rightarrow Z f \bar{f} \) decay

We first consider the decay process \( H \rightarrow Z f \bar{f} \) for a generic fermion \( f \) of mass \( m \), electric charge \( Q \), and color multiplicity \( N \), which is \( N = 1 \) for leptons and \( N = 3 \) for quarks. The \( Z f \bar{f} \) vector and axial-vector couplings are proportional to \( V = 2I - 4s_w^2Q \) and \( A = 2I \), where \( I = \pm 1/2 \) is the third component of weak isospin of the left-handed component of \( f \). Formally, the partial decay width of \( H \rightarrow Z f \bar{f} \) and the one of \( Z \rightarrow H f \bar{f} \), the radiative corrections to which were studied in Ref. [51], are related as [13]

\[
\Gamma_{H \rightarrow Z f \bar{f}} = -3 \left( \frac{z}{h} \right)^{3/2} \Gamma_{Z \rightarrow H f \bar{f}},
\]

(1)

where the minus sign ensures that the phase space remains positive upon the interchange \( z \leftrightarrow h \), and the factors 3, \( \sqrt{z/h} \), and \( z/h \) adjust the spin average, flux, and phase space, respectively. In contrast to Ref. [51], we include here also the finite-\( m \) corrections.

The distribution of the partial decay width \( \Gamma_{H \rightarrow Z f \bar{f}} \) in the \( f \bar{f} \) invariant mass square \( s = q^2 \) may be written as

\[
\frac{d\Gamma_{H \rightarrow Z f \bar{f}}}{ds} = \frac{d\Gamma_{H \rightarrow Z f \bar{f}}^0}{ds} \left[ \delta_0 + \frac{3}{4} \left( \frac{\alpha}{\pi} Q^2 + \frac{\alpha_s}{\pi} C_F \right) \delta_1 + \delta_w - \delta_{xt} + \delta_{\text{res}} \right] \delta_t,
\]

(2)

where

\[
\frac{d\Gamma_{H \rightarrow Z f \bar{f}}^0}{ds} = \frac{G_F^2 z^3}{128 \pi^3 h^{3/2}} N(V^2 + A^2) \frac{C_1}{(s - z)^2},
\]

(3)
with $C_1 = \sqrt{\lambda[4s + \lambda/(3z)]}$ and $\lambda = s^2 + z^2 + h^2 - 2(sz + zh + hs)$, is the tree-level result for $m = 0$ \[52,53\], the factor $\delta_0$ restores the full $m$ dependence of the latter, $C_F = (N^2 - 1)/(2N)$, $\delta_1$ is the coefficient shared by the $O(\alpha)$ QED and $O(\alpha_s)$ QCD corrections, $\delta_w$ contains the purely weak correction at one loop, $\delta_{x_t}$ is the leading $O(x_t)$ term of the latter, the factor $\delta_t$ supplies the leading top-quark-induced corrections at one loop and beyond, and $\delta_{\text{res}}$ comprises the residual higher-order corrections, which are beyond the scope of our present analysis.

It is useful to distinguish between the class of contributions devoid of the $Hf\bar{f}$ Yukawa coupling and the complementary class. The former survives in the massless limit $m \to 0$, and the parts of $\delta_0$ and $\delta_t$ that belong to it are related via the optical theorem to the absorptive part of the Z-boson vacuum polarization tensor induced by the fermion $f$,

$$\Pi^{\mu\nu}(q) = g^{\mu\nu}\Pi_T(s) + q^\mu q^\nu\Pi_L(s), \quad (4)$$

where

$$\Pi_i(s) = \frac{G_F z}{2^{3/2}} \left[ V^2 \Pi_i^V(s) + A^2 \Pi_i^A(s) \right] \quad (i = T, L). \quad (5)$$

While, for $m = 0$, only the transversal part $\Pi_T(s)$ matters, the longitudinal part $\Pi_L(s)$, too, is relevant for $m > 0$. Due to vector current conservation, we have

$$\Pi_T^V(s) + s\Pi_T^L(s) = 0, \quad (6)$$

so that we have to consider only three different coefficient functions. Through the two-loop order, we have \[54,55,56\]

$$\text{Im} \Pi_T^V(s) = \frac{s}{12\pi} N \left[ v_0(r) + \frac{3}{4} \left( \frac{\alpha}{\pi} Q^2 + \frac{\alpha_s}{\pi} C_F \right) v_1(r) \right],$$

$$\text{Im} \Pi_T^A(s) = \frac{s}{12\pi} N \left[ a_0(r) + \frac{3}{4} \left( \frac{\alpha}{\pi} Q^2 + \frac{\alpha_s}{\pi} C_F \right) a_1(r) \right],$$

$$\text{Im} \Pi_L^A(s) = \text{Im} \Pi_L^V(s) - \frac{1}{12\pi} N \left[ l_0(r) + \frac{3}{4} \left( \frac{\alpha}{\pi} Q^2 + \frac{\alpha_s}{\pi} C_F \right) l_1(r) \right], \quad (7)$$

where

$$v_0(r) = \rho \left( 1 + \frac{1}{2r} \right), \quad a_0(r) = \rho^3, \quad l_0(r) = 0, \quad (8)$$

$r v_1(r)$ and $r a_1(r)$ are given by Eqs. (5) and (6) in Ref. \[55\], respectively, $-l_1(r)/(4\pi)$ is given by the second term on the right-hand side of Eq. (13) in Ref. \[56\], $r = s/(4m^2)$, and $\rho = \sqrt{1 - 1/r}$. In Eq. (7), the normalizations are arranged so that $v_i(\infty) = a_i(\infty) = 1$ ($i = 0, 1$), while we have $l_1(r) = 1/r^2 + O(1/r^3)$ for $r \gg 1$.

The correction terms in Eq. (2) may now be presented in a compact form. Specifically, we have

$$\delta_i = \frac{1}{V^2 + A^2} \left\{ V^2 v_i(r) + A^2 a_i(r) + \frac{(s - z)^2}{C_1} \left[ -\frac{\lambda^{3/2}}{3z^3} A^2 (a_i(r) - v_i(r) - l_i(r)) + y_i \right] \right\}, \quad (9)$$
where \( y_0 \) and \( y_1 \) represent, respectively, the tree-level and one-loop corrections involving one or two powers of the \( Hf \bar{T} \) Yukawa coupling. For \( m = 0 \), we have \( \delta_t = 1 \), so that \( \delta_t - 1 \) measures the relative finite-\( m \) correction at tree level (\( i = 0 \)) or at one loop in QED and QCD (\( i = 1 \)). For \( y_0 \), we find

\[
y_0 = \frac{2m^2}{z^2(z - s)} \left\{ \rho \sqrt{\lambda} \left[ - (V^2(z + 2m^2) + A^2(z - 4m^2)) \frac{s(z - s)(h - 4m^2)}{h z s + m^2 \lambda} - 4V^2 z + A^2 \right. \right.
\]
\[
\times \left. \left( 6z + s - \frac{s}{z}(2h - s) \right) \right] + V^2 L \left[ 3z^2 - z(7h - 6s) - 2h^2 - hs - s^2 + 4m^2(h + 2s) \right.
\]
\[
- 16m^4 + 2h \frac{h^2 - 2m^2(5h - 2s) + 8m^4}{h + z - s} \left. \right] + A^2 L \left[ 3z^2 + z(h + 6s) + (h - s)(2h + s) \right.
\]
\[
- 2m^2 \left( 13z - h + 6s + \frac{(h - s)(2h - s)}{z} \right) + 32m^4 - 2h \frac{h^2 - 4m^2(h + s) + 16m^4}{h + z - s} \right\},
\]

where

\[
L = \ln \frac{h + z - s - \rho \sqrt{\lambda}}{h + z - s + \rho \sqrt{\lambda}}.
\]

As we shall see in Sec. 3 the contribution to \( \delta_0 \) proportional to \( y_0 \) is exceedingly small. Our result for \( y_1 \) is too lengthy to be presented here.

Furthermore, we have

\[
\delta_w = 2 \Re \Delta_{\text{weak}} + \delta_m,
\]

where the \( m = 0 \) part \( \Delta_{\text{weak}} \) is listed in analytic form in Ref. 48 and \( \delta_m \) comprises the finite-\( m \) correction. We include \( \delta_m \) in our numerical analysis, although it turns out to be small against \( \Delta_{\text{weak}} \), but we refrain from presenting here our analytic expression for it because it is too lengthy.

Finally, using the improved Born approximation (IBA) 57, we obtain

\[
\delta_t = \frac{(1 + \delta_{ZZH})^2}{1 - \Delta \rho} \frac{(V - 4c_w^2Q\Delta \rho)^2 + A^2}{V^2 + A^2}
\]
\[
= 1 + 2\delta_{ZZH} + (1 - 8X)\Delta \rho + \delta_{ZZH}^2 + 2(1 - 8X)\delta_{ZZH}\Delta \rho + (1 - 8X + 16Y)(\Delta \rho)^2
\]
\[
+ \mathcal{O}(x_t^3),
\]

where \((1 + \delta_{ZZH})\) is the correction to the heavy-top-quark effective Lagrangian of the \( ZZH \) interaction, \( \Delta \rho = 1 - 1/\rho \) measures the deviation of the electroweak \( \rho \) parameter from unity, \( X = c_w^2 Q V/(V^2 + A^2) \), and \( Y = c_w^4 Q^2/(V^2 + A^2) \). Including the corrections of \( \mathcal{O}(x_t) \) 23, 42, 43, 53, 49, \( \mathcal{O}(x_t^2) \) 19, 60, \( \mathcal{O}(x_t\alpha_s) \) 46, 61, and \( \mathcal{O}(x_t\alpha_s^2) \) 36, 62, we have

\[
\delta_{ZZH} = x_t \left\{ -\frac{5}{2} - \left[ \frac{177}{8} + 18\zeta(2) \right] x_t + [15 - 2\zeta(2)] a_s + 17.117 a_s^2 \right\},
\]
\[
\Delta \rho = x_t \left\{ 3 + 3 [19 - 12\zeta(2)] x_t - 2[1 + 2\zeta(2)] a_s - 43.782 a_s^2 \right\},
\]

\[
(14)
\]

\[
(10)
\]

\[
(11)
\]

\[
(12)
\]
where \( \zeta(2) = \pi^2/6 \) and \( a_s = \alpha_s^6(m_t)/\pi \). Analytic expressions for the \( \mathcal{O}(\alpha_s^2) \) terms in Eq. (14) may be found in Refs. [36,62]. To avoid double counting, the \( \mathcal{O}(\alpha_s) \) term of Eq. (13) [48,51],

\[
\delta_x = -2x(1 + 12X),
\]

is subtracted in Eq. (2).

A more conservative form of Eq. (2) is obtained by discarding the quantities \( \delta_x \) and \( \delta_t \), and in turn introducing within the square brackets the term \( \delta_{\text{ho}} \) that contains the leading top-quark-induced corrections beyond one loop. In the leptonic case \( f = l \), which is of special interest here, we have

\[
\delta_{\text{ho}} = \delta_t - \delta_x = \{13 - 72\zeta(2) + 24(-17 + 12\zeta(2))X + 144Y\}x_t^2 + 4\{7 - 2\zeta(2) + 4[1 + 2\zeta(2)]X\}x_t a_s + (-9.548 + 350.257X)x_t a_s^2.
\]

Finally, \( \Gamma^0_{H \rightarrow Zf\bar{f}} \) is obtained by integrating Eq. (2) over the interval \( 4m^2 < s < (m_H - m_Z)^2 \). The tree-level result for \( m = 0 \) reads [53]

\[
\Gamma^0_{H \rightarrow Zf\bar{f}} = \frac{G^2 F^4 z^4}{128\pi^3 h^{3/2}} N(V^2 + A^2) \left[-F \left(\frac{h}{z}\right)\right],
\]

where \( F(x) \) is given in Eq. (3) of Ref. [51]. For the reader’s convenience, we reproduce this formula here:

\[
F(x) = \frac{1 - x}{x} \left(-\frac{47}{2} + \frac{13}{2} x - x^2\right) + \left(-2 + 3x - \frac{x^2}{2}\right)\ln x
\]

\[
+ \left(10 - 4x + \frac{x^2}{2}\right) \sqrt{\frac{x}{4 - x}} \left(\pi - 6\arcsin\frac{\sqrt{x}}{2}\right).
\]

The origin of the minus sign on the right-hand side of Eq. (17) is explained in Eq. (1).

### 2.2 \( H \rightarrow W^+ f \bar{f}' \) decay

We now consider the decay process \( H \rightarrow W^+ f \bar{f}' \), where \( f \) is a generic fermion with weak isospin \( I = -1/2 \) and \( f' \) is an appropriate fermion with \( I = 1/2 \). By charge-conjugation invariance, the process \( H \rightarrow W^- f'\bar{f} \) has the same partial decay width.

Some of the expressions for \( H \rightarrow Z f \bar{f} \) in Sec. 2.1 carry over to \( H \rightarrow W^+ f \bar{f}' \). Specifically, the counterparts of Eqs. (1), (3), (4), (5), and (17) are obtained by substituting \( z \rightarrow w \) and \( V, A \rightarrow \sqrt{2} \), and including the overall factor \( |V_{f'f}|^2 \), where \( V_{f'f} \) is the Cabibbo-Kobayashi-Maskawa quark mixing matrix, if \( f \) and \( f' \) are quarks. However, structural differences occur because the intermediate boson is now electrically charged. In particular, the separation of QED and weak corrections is no longer meaningful at one loop because

\begin{footnote}{In the journal publication [51], this equation contains a misprint, which is absent in the preprint: \( \sqrt{\frac{1}{4} x - x} \) should replace by \( \sqrt{\frac{1}{4-x}} \).}
\end{footnote}
the photonic loop diagrams, including the appropriate counterterm diagrams, no longer form a gauge-independent and ultraviolet-finite subset \[13,41\]. Furthermore, in the case when \( f \) and \( f' \) are quarks, the one-loop QCD correction is no longer proportional to the QED correction. As a consequence, the distribution of the partial decay width \( \Gamma_{H \to W^+ f f'} \) in the \( f f' \) invariant mass square \( s = q^2 \) now takes the form

\[
\frac{d\Gamma_{H \to W^+ f f'}}{ds} = \frac{d\Gamma^0_{H \to W^+ f f'}}{ds} \left( \delta_0 + \frac{3}{4} \frac{\alpha_s}{\pi} C_F \delta_1 + \delta_{ew} - \delta_{\text{res}} \right) \delta_t. \tag{19}
\]

In view of \( m_\nu \ll m_\ell \) and \( m_\ell \ll m_e \), we may safely neglect the mass of the lighter one of the two fermions \( f \) and \( f' \) and call the mass of the heavier one \( m \). Due to the \( \gamma_5 \) reflection property \( \Pi^V_i(s, m_1, m_2) = \Pi^A_i(s, m_1, -m_2) \) \((i = T, L)\), we then have \[54,55,56\]

\[
\Pi^V_i(s) = \Pi^A_i(s). \tag{20}
\]

Through the two-loop order, we have \[54,55,56\]

\[
\begin{aligned}
\text{Im} \Pi^V_T(s) &= \frac{s}{12\pi} N \left[ f_0(x) + \frac{3}{4} \frac{\alpha_s}{\pi} C_F f_1(x) \right], \\
\text{Im} \Pi^V_L(s) &= -\frac{1}{12\pi} N \left[ g_0(x) + \frac{3}{4} \frac{\alpha_s}{\pi} C_F g_1(x) \right],
\end{aligned}
\tag{21}
\]

where

\[
\begin{aligned}
f_0(x) &= \left( 1 + \frac{1}{2x} \right) \left( 1 - \frac{1}{x} \right)^2, \\
g_0(x) &= \left( 1 + \frac{2}{x} \right) \left( 1 - \frac{1}{x} \right)^2,
\end{aligned}
\tag{22}
\]

\( x f_1(x)/4 \) is given by Eq. (7) in Ref. \[55\], \( -g_1(x)/4 \) is given by Eq. (14) in Ref. \[56\], and \( x = s/m^2 \). In Eq. (7), the normalizations are arranged so that \( f_i(\infty) = g_i(\infty) = 1 \) \((i = 0, 1)\).

Then, we have

\[
\delta_i = f_i(x) + \frac{(s - w)^2}{C_1} \left\{ -\frac{\lambda^{3/2}}{3w^3} [f_i(x) - g_i(x)] + y_i \right\}, \tag{23}
\]

where \( C_1 \) and \( \lambda \) are defined as below Eq. (3), but with \( z \) replaced by \( w \). For \( y_0 \), we find

\[
y_0 = \frac{m^2}{2w^3 s^2 (w - s)} \left\{ \sqrt{\lambda} \left[ s^3 (3w + s) - 2h(s - m^2) (s^2 + 2m^2 (w - s)) + 2m^2 w (w + s) \right. \right. \\
\times (s - 2m^2) + \frac{m^2 s^2 (w - s)^2 (w + m^2) (w + s - m^2)^2}{h (w - m^2) (s - m^2) + m^2 (w - s)^2} \left. \left] + s^2 L \left[ 2w (3w (-h + w + 2s) \right. \right. \\
\left. - s(h + s) + m^2 (w (9h - 5w - 2s) + s (3h - s)) - 4m^4 (h + w + s) \right] \right\}, \tag{24}
\]

where

\[
L = \ln \frac{(s + m^2) (w - s) + (s - m^2) (h - \sqrt{\lambda})}{(s + m^2) (w - s) + (s - m^2) (h + \sqrt{\lambda})}. \tag{25}
\]
As will be shown in Sec. 3, the contribution proportional to \( y_0 \) is very small compared to \( \delta_0 \). For lack of space, we do not present \( y_1 \) and \( \delta_{\text{ew}} \) in analytic form. Furthermore, we have

\[
\delta_t = (1 + \delta_{WWH})^2. \tag{26}
\]

Including the corrections of \( O(x_t) \) \[23,41,43,58\], \( O(x_t^2) \) \[19\], \( O(x_t \alpha_s) \) \[45\], and \( O(x_t \alpha_s^2) \) \[36\], we have

\[
\delta_{WWH} = x_t \left\{ -\frac{5}{2} + \left[ \frac{39}{8} - 18\zeta(2) \right] x_t + \left[ 9 - 2\zeta(2) \right] a_s + 27.041 a_s^2 \right\}. \tag{27}
\]

An analytic expression for the \( O(x_t \alpha_s^2) \) term may be found in Ref. [36]. The \( O(x_t) \) term of Eq. (26) is

\[
\delta_{x_t} = -5x_t. \tag{28}
\]

Again, we may trade the quantities \( \delta_{x_t} \) and \( \delta_t \) in Eq. (19) against the term \( \delta_{\text{ho}} \), carrying the leading top-quark-induced corrections beyond one loop, to be inserted within the parentheses. In the leptonic case, we have

\[
\delta_{\text{ho}} = \delta_t - 1 - \delta_{x_t}
= 4[4 - 9\zeta(2)]x_t^2 + 2[9 - 2\zeta(2)]x_t a_s + 54.082 x_t a_s^2. \tag{29}
\]

3 Numerical results

We are now in a position to explore the phenomenological consequences of our results by performing a numerical analysis. We adopt all the input parameter values from Ref. [63]. Specifically, we use \( m_W = 80.385 \text{ GeV} \), \( m_Z = 91.1876 \text{ GeV} \), \( m_b = 4.78 \text{ GeV} \), \( m_t = 173.5 \text{ GeV} \), and \( \alpha_s^6(m_t) = 0.1080 \), which follows from \( \alpha_s^5(m_Z) = 0.1184 \) via four-loop evolution and three-loop matching [64]. In our renormalization scheme, \( \sin^2 \theta_w = 1 - m_W^2/m_Z^2 = 0.222897 \) and \( \alpha = \sqrt{2G_F} \sin^2 \theta_w m_W^2/\pi = 1/132.233 \) are derived parameters.

We first consider the \( H \to Z\ell^+\ell^- \) decays. In Fig. 1 we present the tree-level finite-m (dotted lines) and radiative (solid lines) corrections to (a) \( d\Gamma(H \to Z\tau^+\tau^-)/ds \) for \( m_H = 125 \text{ GeV} \) as functions of \( \sqrt{s} \), and to (b) \( \Gamma(H \to Z\tau^+\tau^-) \) and (c) \( \Gamma(H \to Z\mu^+\mu^-) \) as functions of \( m_H \). The radiative corrections are decomposed into the \( O(\alpha) \) QED (coarsely dotted lines), \( O(\alpha) \) weak (dashed lines), and dominant higher-order (dot-dashed lines) corrections, of \( O(x_t^2) \), \( O(x_t \alpha_s) \), and \( O(x_t \alpha_s^2) \). For comparison, the \( O(\alpha) \) corrections predicted by the IBA (dot-dot-dashed lines) are also shown. Looking at Fig. 1(a), we observe that the QED correction \( 3\alpha \delta_t/(4\pi) \) exhibits an enhancement towards low values of \( \sqrt{s} \), which is of Coulomb origin, while it gets close to its asymptotic value \( 3\alpha/(4\pi) \) as \( \sqrt{s} \) approaches its kinematic upper bound. The purely weak correction \( \delta_w \) monotonically increases with \( \sqrt{s} \), ranging from slightly negative values at the \( \tau^+\tau^- \) pair production threshold to about\( (m_H - m_W)^2 \).
Figure 1: Tree-level finite-$m$ (dotted lines) and radiative (solid lines) corrections to (a) $d\Gamma(H \to Z\tau^+\tau^-)/ds$ for $m_H = 125$ GeV as functions of the $\tau^+\tau^-$ invariant mass $\sqrt{s}$, and to (b) $\Gamma(H \to Z\tau^+\tau^-)$ and (c) $\Gamma(H \to Z\mu^+\mu^-)$ as functions of $m_H$. The radiative corrections include the $\mathcal{O}(\alpha)$ QED (coarsely dotted lines), $\mathcal{O}(\alpha)$ weak (dashed lines), and dominant higher-order (dot-dashed lines) corrections of $\mathcal{O}(\alpha^2 t)$, $\mathcal{O}(x_t \alpha_s)$, and $\mathcal{O}(x_t \alpha_s^2)$. For comparison, the $\mathcal{O}(\alpha)$ corrections predicted by the IBA (dot-dot-dashed lines) are also shown.

Looking at Fig. 1(a), we observe that the finite-$m$ correction to $\Gamma(H \to Z\tau^+\tau^-)$ ranges from $-7.9\%$ to $-3.1\%$ in the considered mass window $115$ GeV $< m_H < 130$ GeV and more than compensates the overall radiative correction, which ranges there between $0.6\%$ and $1.9\%$. From Fig. 1(b), we read off that the finite-$m$ correction to $\Gamma(H \to Z\mu^+\mu^-)$ is below $0.03\%$ in magnitude.

In Fig. 2(a), we present our best predictions for $d\Gamma(H \to Z\tau^+\tau^-)/ds$ (solid line) and $d\Gamma(H \to Z\mu^+\mu^-)/ds$ (dashed line) for $m_H = 125$ GeV as functions of $\sqrt{s}$ including both finite-$m$ and radiative corrections. For comparison, the tree-level result for $m = 0$ (dotted line) is also shown. The relation of the solid line shape to the dotted one may be easily understood from Fig. 1(a). The essential feature of the dashed line shape in comparison
Figure 2: (a) $d\Gamma(H \rightarrow Z\ell^+\ell^-)/ds$ for $m_H = 125$ GeV as a function of the $\ell^+\ell^-$ invariant mass $\sqrt{s}$, and (b) $\Gamma(H \rightarrow Z\ell^+\ell^-)$ as a function of $m_H$ at the tree level for $m = 0$ (dotted lines) and including both finite-$m$ and radiative corrections for $\ell = \mu$ (dashed lines) and $\ell = \tau$ (solid lines).

Figure 3 shows the tree-level finite-$m$ (dotted lines) and radiative (solid lines) corrections to (a) $d\Gamma(H \rightarrow W^+\tau^-\nu_{\tau})/ds$ for $m_H = 125$ GeV as functions of $\sqrt{s}$, and to (b) $\Gamma(H \rightarrow W^+\tau^-\tau)$ and (c) $\Gamma(H \rightarrow W^+\mu^-\tau)$ as functions of $m_H$. The radiative corrections are built up by the $\mathcal{O}(\alpha)$ electroweak (dashed lines) and dominant higher-order (dot-dashed lines) corrections of $\mathcal{O}(x_t^2)$, $\mathcal{O}(x_t\alpha_s)$, and $\mathcal{O}(x_t\alpha_s^2)$. For comparison, the $\mathcal{O}(\alpha)$ corrections predicted by the IBA (dot-dot-dashed lines) are also presented. Looking at Fig. 3(a), we observe that the electroweak correction $\delta_{\text{ew}}$ monotonically increases with $\sqrt{s}$, ranging from slightly negative values at the $\tau^-\nu_{\tau}$ pair production threshold to about 4.5% at the upper endpoint. The one-loop electroweak correction is again inadequately described by the IBA term $\delta_{\text{tt}}$. The dominant higher-order correction $\delta_{\text{ho}}$ amounts to about 0.1% altogether.

Comparing Figs. 3(a)–(c) with Figs. 1(a)–(c), we observe that the finite-$m$ corrections for the $H \rightarrow W^+\ell^-\nu_\ell$ decays are significantly smaller than for the respective $H \rightarrow Z\ell^+\ell^-$ decays. This is mainly due to the fact that the shrinkage of the available phase space caused by switching on the finite-$m$ corrections is lesser for the $H \rightarrow W^+\ell^-\nu_\ell$ decays.

In Fig. 2(b), our best predictions for $\Gamma(H \rightarrow Z\tau^+\tau^-)$ (solid line) and $\Gamma(H \rightarrow Z\mu^+\mu^-)$ (dashed line) as functions of $m_H$ are compared with the tree-level result for $m = 0$ (dotted line). The relative shifts of the solid and dashed line shapes with respect to the dotted one immediately follow from Figs. 1(b) and (c), respectively.

We now turn to the $H \rightarrow W^+\ell^-\nu_\ell$ decays. Figure 3 shows the tree-level finite-$m$ (dotted lines) and radiative (solid lines) corrections to (a) $d\Gamma(H \rightarrow W^+\tau^-\nu_\tau)/ds$ for $m_H = 125$ GeV as functions of $\sqrt{s}$, and to (b) $\Gamma(H \rightarrow W^+\tau^-\tau)$ and (c) $\Gamma(H \rightarrow W^+\mu^-\nu_\mu)$ as functions of $m_H$. The radiative corrections are built up by the $\mathcal{O}(\alpha)$ electroweak (dashed lines) and dominant higher-order (dot-dashed lines) corrections of $\mathcal{O}(x_t^2)$, $\mathcal{O}(x_t\alpha_s)$, and $\mathcal{O}(x_t\alpha_s^2)$. For comparison, the $\mathcal{O}(\alpha)$ corrections predicted by the IBA (dot-dot-dashed lines) are also presented. Looking at Fig. 3(a), we observe that the electroweak correction $\delta_{\text{ew}}$ monotonically increases with $\sqrt{s}$, ranging from slightly negative values at the $\tau^-\nu_\tau$ pair production threshold to about 4.5% at the upper endpoint. The one-loop electroweak correction is again inadequately described by the IBA term $\delta_{\text{tt}}$. The dominant higher-order correction $\delta_{\text{ho}}$ amounts to about 0.1% altogether.

Comparing Figs. 3(a)–(c) with Figs. 1(a)–(c), we observe that the finite-$m$ corrections for the $H \rightarrow W^+\ell^-\nu_\ell$ decays are significantly smaller than for the respective $H \rightarrow Z\ell^+\ell^-$ decays. This is mainly due to the fact that the shrinkage of the available phase space caused by switching on the finite-$m$ corrections is lesser for the $H \rightarrow W^+\ell^-\nu_\ell$ decays.
because the lepton pair production threshold is twice as low, at $\sqrt{s} = m$, and the upper endpoint is located higher, by $m_Z - m_W \approx 11$ GeV, also leading to correspondingly higher maxima of the $\sqrt{s}$ distributions. In fact, the finite-$m$ correction $\delta_0 - 1$ to $d\Gamma(H \to W^+\tau^-\nu_\tau)/ds$ in Fig. 3(a) rapidly relaxes from its threshold value of $-100\%$ to moderate values, passing $-1\%$ at $\sqrt{s} \approx 8$ GeV and reaching $-0.2\%$ at the upper endpoint. As anticipated in Sec. 2.2 the relative contribution of $y_0$ to $\delta_0$, proportional to the $H\tau^+\tau^-$ coupling, is very small, below $0.17\%$, over the full $\sqrt{s}$ range.

From Fig. 3(b), we learn that the finite-$m$ correction to $\Gamma(H \to W^+\tau^-\nu_\tau)$ ranges from $-1.1\%$ to $-0.5\%$ in the considered mass window $115$ GeV $< m_H < 130$ GeV and reduces the radiative corrections by between $38\%$ to $14\%$. On the other hand, Fig. 3(c) tells us that the finite-$m$ correction to $\Gamma(H \to W^+\mu^-\nu_\mu)$ is absolutely negligible, being below $0.004\%$ in magnitude.

In Fig. 4(a), our final predictions for $d\Gamma(H \to W^+\tau^-\nu_\tau)/ds$ (solid line) and $d\Gamma(H \to W^+\mu^-\nu_\mu)/ds$ (dashed line) for $m_H = 125$ GeV are shown as functions of $\sqrt{s}$ and compared with the tree-level result for $m = 0$ (dotted line), so as to expose the interplay of the finite-$m$ and radiative corrections. In Fig. 4(b), the same is done for $\Gamma(H \to W^+\tau^-\nu_\tau)$ and $\Gamma(H \to W^+\mu^-\nu_\mu)$ as functions of $m_H$.

4 Conclusions

We presented a precision study of the partial widths of the $H \to Z\ell^+\ell^-$ and $H \to W^+\ell^-\nu_\ell$ decays, including the full one-loop electroweak corrections and the dominant contributions at two and three loops, of $O(x_t^2)$, $O(x_t\alpha_s)$, and $O(x_t\alpha_s^2)$. We also included
finite-m corrections, which turned out to be indispensable for $\ell = \tau$, but negligible for $\ell = \mu, e$. Working in the on-mass-shell renormalization scheme with $G_F$ replacing $\alpha$ as a basic parameter, we ensured that the radiative corrections remained moderate in size, being devoid of large logarithms involving small masses of charged fermions. As for the integrated partial decay widths, we found the net corrections relative to the tree-level results for $m = 0$ at $m_H = 125$ GeV to be $+1.6\%$ for $H \to Z e^+ e^-$ and $H \to Z \mu^+ \mu^-$, $-2.5\%$ for $H \to Z \tau^+ \tau^-$, $+3.6\%$ for $H \to W^+ e^- \bar{\nu}_e$ and $H \to W^+ \mu^- \bar{\nu}_\mu$, and $+2.8\%$ for $H \to W^+ \tau^- \bar{\nu}_\tau$.
