The charged McVittie spacetime

Valerio Faraoni,† Valerio Faraoni,1,‡ Andres F. Zambrano Moreno,1,‡ and Angus Prain1,†

Sherbrooke, Québec, Canada J1M 1Z7

The two-parameter charged McVittie solution of the Einstein equations is revisited and its apparent horizons are discussed and located numerically (for the extremal case, analytically). According to the parameter values, this spacetime can be interpreted as a black hole, or a spacelike naked singularity, in a spatially homogeneous and isotropic universe.

PACS numbers: 98.80.-k, 04.50.+h

I. INTRODUCTION

Analytical solutions of general relativity and of alternative theories of gravity which represent inhomogeneous cosmologies have been the subject of much recent interest. In the context of general relativity, spherically symmetric solutions of this kind are used to explore alternatives to dark energy in explaining the current acceleration of the cosmic expansion (see Ref. [1] for a review), to study the effect of the cosmic dynamics on local systems [2], to study the spatial variation of fundamental constants [3], and to explore the thermodynamics of time-dependent horizons [4–7]. Solutions representing time-varying black holes are of interest in themselves and the first spacetime of this kind is the 1933 McVittie solution of the Einstein equations constructed to study the effect of the cosmic dynamics on a local system [8]. It describes a central inhomogeneity in a Friedmann-Lemaître-Robertson-Walker (FLRW) “background”. Over the years, the McVittie solution has been the subject of many studies [9–16] and was discussed very briefly in [20, 21]. Here we want to refine the rather cursory analysis of this metric presented in these references and, in particular, locate its apparent horizons (when present) — this is the case of the cuscuton theory, a special case of Horava-Lifschitz theory, of which the McVittie metric is a solution [17].

A charged version of the original McVittie metric was found by Gao and Zhang [18], who also generalized it to higher dimensions [19], and was discussed very briefly in [20, 21]. Here we want to refine the rather cursory analysis of this metric presented in these references and, in particular, locate its apparent horizons (when present) and study their dynamics.

Conformal diagrams of the McVittie spacetime for various backgrounds were obtained in [12, 16] and we expect them to be qualitatively similar in the charged case; however we do not get into such level of detail here. As an application of the charged McVittie spacetime, we mention that it was used [4] to disprove the universality of certain quantization laws for quantities constructed with the areas of black hole apparent horizons and inspired by string theories [22].

II. THE CHARGED MCVITTIE SPACETIME AND ITS APPARENT HORIZONS

For simplicity we restrict ourselves to a spatially flat FLRW “background” (we use quotation marks because, due to the non-linearity of the Einstein equations, it is in general impossible to split a metric into a background and a deviation from it in a covariant way). The spherically symmetric, non-stationary, charged McVittie line element and the only nonvanishing component of the Maxwell tensor are

\[
ds^2 = -\left[1 - \frac{(m^2 - Q^2)}{4a^2r^2}\right]^2 dt^2 + a^2(t) \left[1 + \frac{m}{2ar}\right]^2 - \frac{Q^2}{4a^2r^2}\left(dr^2 + r^2d\Omega^2\right),
\]

(1)

\[
F^{01} = \frac{Q}{a^2r^2\left[1 - \frac{(m^2 - Q^2)}{4a^2r^2}\right]\left(1 + \frac{m}{2ar}\right)^2 - \frac{Q^2}{4a^2r^2}}
\]

(2)

where \(r\) is the isotropic radius, \(d\Omega^2 = d\theta^2 + \sin^2\theta d\phi^2\) is the line element on the unit 2-sphere, the constants \(m > 0\) and \(Q\) are a mass and an electric charge parameter, respectively, and \(a(t)\) is the scale factor of the

---

1 The analysis of Ref. [22] is flawed by a typographical error present in the metric of [18] but, as we shall see, the qualitative behaviour of the apparent horizons for \(|Q| \leq m\) does not change and the argument of Ref. [22] still stands.
2 Our notations differ slightly from those of Ref. [18]. Beware of a typographical error in the numerator of \(\gamma_{00}\) in [18], which was corrected in Refs. [19, 21].

vfaraoni@ubishops.ca
azambrano07@ubishops.ca
aprain@ubishops.ca
“background” FLRW universe. If \(a = 1\), the line element reduces to the Reissner-Nordström one in isotropic coordinates while, for large values of \(r\), it reduces to the spatially flat FLRW metric. If \(m = Q = 0\), the metric becomes an exact spatially flat FLRW one.

The inspection of eq. (1) provides immediately the areal radius

\[
R(t,r) = a(t)r \left[ \left( 1 + \frac{m}{2a(t)r} \right)^2 - \frac{Q^2}{4a^2(t)r^2} \right] = m + a(t)r + \frac{m^2 - Q^2}{4a(t)r}
\]

and it is \(R(t,r) \geq m\) for \(|Q| \leq m\). Assuming the range of parameters \(|Q| \leq m\), the function \(R(t,r)\) (and consequently also the area \(4\pi R^2\) of 2-spheres of symmetry) decreases from \(+\infty\) in the range \(0 < ar \leq \sqrt{m^2 - Q^2}/2\), has an absolute minimum \(R_{\text{min}} = m + \sqrt{m^2 - Q^2}\) at \(ar = \sqrt{m^2 - Q^2}/2\), and increases again to plus infinity for \(ar > \sqrt{m^2 - Q^2}/2\), which shows clearly that the isotropic radius corresponds to a double covering of the spacetime region \(R > m + \sqrt{m^2 - Q^2} \geq m\). (This fact is well known for the Schwarzschild spacetime \([22]\), which is contained in the metric \(\Pi\) as the special case \(a = 1, Q = 0\).)

In the case \(|Q| \geq m\), the areal radius \(R\) is instead a monotonically increasing function of \(r\) and the physically meaningful region \(R \geq 0\) corresponds to \(r \geq \frac{(|Q| - m)}{2ar} \geq 0\).

The relation between areal radius \(R\) and isotropic radius \(r\) can be inverted, which will be useful in the following to study the horizons of the charged McVittie spacetime. This inversion gives the quadratic equation

\[
2ar = R - m + \sqrt{R^2 + Q^2 - 2mR} \equiv f(R).
\]

The Ricci scalar is found to be

\[
R^c_e = \frac{6}{1 - \frac{(m^2 - Q^2)}{4a^2r^2}} \left\{ \frac{\dot{a}}{a} \left( 1 + \frac{m}{2ar} \right)^2 - \frac{Q^2}{4a^2r^2} \right\} + H^2 \left[ 1 - \frac{m}{ar} + 3 \frac{(Q^2 - m^2)}{4a^2r^2} \right].
\]

The non-zero components of the Einstein tensor are

\[
G^t_t = -\frac{256Q^2r^4a^4}{[m^2 - Q^2 + 4mra + 4r^2a^2]^4} + \frac{3\dot{a}^2}{a^2},
\]

\[
G^r_r = \frac{256Q^2r^4a^4}{[m^2 - Q^2 + 4mra + 4r^2a^2]^4} + \frac{\dot{a}^2(-5m^2 + 5Q^2 - 8mra + 4r^2a^2)}{a^2(-m^2 + Q^2 + 4r^2a^2)} + \frac{2\dot{a}(m^2 - Q^2 + 4mra + 4r^2a^2)}{a(-m^2 + Q^2 + 4r^2a^2)},
\]

\[
G^\theta_\theta = G^{\varphi}_\varphi = -\frac{256Q^2r^4a^4}{[m^2 - Q^2 + 4mra + 4r^2a^2]^4} + \frac{\dot{a}^2(-5m^2 + 5Q^2 - 8mra + 4r^2a^2)}{a^2(-m^2 + Q^2 + 4r^2a^2)} + \frac{2\dot{a}(m^2 - Q^2 + 4mra + 4r^2a^2)}{a(-m^2 + Q^2 + 4r^2a^2)}.
\]

\(H \equiv \dot{a}/a\) is the Hubble parameter of the FLRW “background” and an overdot denotes differentiation with respect to the comoving time \(t\). The vanishing of \(G^t_t\) implies that there is no accretion (which, to respect the symmetry, could only be radial) of cosmic fluid onto the central object.

For \(m = Q = 0\), eq. (3) reduces to the well known Ricci scalar of the spatially flat FLRW universe \(R^c_e = 6 \left( \dot{H} + 2H^2 \right)\). For \(a = 1\) it reduces to zero, which is the Ricci scalar of the Reissner-Nordström spacetime (the only source of matter is then the Maxwell field with traceless energy-momentum tensor). If \(|Q| \leq m\) there is a singularity where \(1 - \frac{(m^2 - Q^2)}{4a^2r^2} = 0\), or

\[
ar = \frac{\sqrt{m^2 - Q^2}}{2},
\]

with the positive root satisfying the relation

\[
2ar = R - m + \sqrt{R^2 + Q^2 - 2mR} = f(R).
\]

The vanishing of the Einstein tensor in Refs. \([20]\) and \([21]\) differs from ours in that, there, a scale factor term is missing in the combination \([m^2 - Q^2 + 4mra + 4r^2a^2]^4\) in the denominators.
This new spherical singularity is not present if \( |Q| > m \). In this case, however, the scalar invariant of the Maxwell tensor

\[
F_{ab}F^{ab} = -\frac{Q^2}{a^2 r^4 \left[ (1 + \frac{m}{2ar})^2 - \frac{Q^2}{4a^2 r^2} \right]^2}
\]

(13)

diverges at

\[
ar = \frac{|Q| - m}{2}.
\]

(14)
corresponding to \( R = 0 \) due to the divergence of the radial electric field, which is the only non-zero component \( F^{01} \) of the Maxwell tensor. Of course, the Big Bang singularity is always present at \( a = 0 \). The singularity (11) divides the spacetime into two disconnected manifolds, as in the McVitte case [3, 29].

The spacetime singularity (11) (for \( |Q| \leq m \)) is spacelike. In fact, this singularity corresponds to \( \psi = 0 \), where

\[
\psi(t, r) \equiv a(t) r - \frac{\sqrt{m^2 - Q^2}}{2};
\]

(15)

we have

\[
\nabla_c \psi \nabla^c \psi = -\dot{a}^2 r^2 \left[ \left( 1 + \frac{m}{2ar} \right)^2 - \frac{Q^2}{4a^2 r^2} \right]^2
\]

\[
+ \frac{1}{\left[ \left( 1 + \frac{m}{2ar} \right)^2 - \frac{Q^2}{4a^2 r^2} \right]^2}.
\]

(16)

In the limit in which \( 2ar \to \sqrt{m^2 - Q^2} \) from above, this expression tends to \( -\infty \), therefore the norm of the normal to the surfaces \( \psi = \text{const.} \) in this limit is negative, hence this surface and its limit are spacelike.

The black hole nature of the charged McVitte spacetime is assessed by examining its horizons. Since the metric is dynamical, the relevant concept of horizon is not the null and teleological event horizon, which requires the knowledge of the entire spacetime manifold to future null infinity. Apparent and trapping horizons, instead, are more appropriate and useful concepts to describe dynamical situations [3, 24, 29], and we will study the apparent horizons, which are located by the equation \( \nabla_c R \nabla^c R = 0 \) (e.g., [3, 27, 28]), where \( R \) is the areal radius. After straightforward manipulations, this equation becomes

\[
\dot{a}^2 r^2 \left[ \left( 1 + \frac{m}{2ar} \right)^2 - \frac{Q^2}{4a^2 r^2} \right]^4
\]

\[- \left[ 1 - \frac{(m^2 - Q^2)}{4a^2 r^2} \right]^2 \]

\[- \left[ \left( 1 + \frac{m}{2ar} \right)^2 - \frac{Q^2}{4a^2 r^2} \right]^{-2} = 0.
\]

(17)

Excluding the singularity \( \Psi \), the roots of \( \Psi \) are the roots of the equation

\[
\dot{a}^2 r^2 \left[ \left( 1 + \frac{m}{2ar} \right)^2 - \frac{Q^2}{4a^2 r^2} \right]^4 = \left[ 1 - \frac{(m^2 - Q^2)}{4a^2 r^2} \right]^2.
\]

(18)

It is useful to express the location of the apparent horizons in terms of the physical (areal) radius, obtaining

\[
4f^2 R^4 H^2 - \left( f^2 - m^2 + Q^2 \right)^2 = 0,
\]

(19)

where \( f(R) \) is given by eq. (5). Equation (19) can be manipulated without further approximation to the quartic polynomial in \( R \)

\[
H^2 R^4 - R^2 + 2mR - Q^2 = 0.
\]

(20)

Note that this polynomial is general and applies independently of the relation of \( Q \) to \( m \). For large values of \( R \) this equation reduces to \( R \approx 1/H \), the value of the radius of the apparent horizon of the spatially flat FLRW “background”, which makes us expect a cosmological horizon to be present. In any regime in which \( H \to 0 \) (for example in power law backgrounds with \( a(t) = a_0 t^p \) and hence \( H = p/t \to 0 \) as \( t \to \infty \)), eq. (19) reduces to its asymptotic form

\[
R^2 - 2mR + Q^2 \simeq 0
\]

(21)

so that, in this limit

\[
R = m \pm \sqrt{m^2 - Q^2}
\]

(22)

implying that at late times in any region of a background for which \( H \to 0 \) (for example late times in a power law background) a black hole apparent horizon asymptotes to the singularity \( \Psi \) from above. Note that the smaller root always lies inside the spherical singularity and that these two roots exactly coincide with the locations of the two event horizons of Reissner-Nordström. Hence we see that the limit \( H \to 0 \) reproduces the horizon structure of the static Reissner-Nordström spacetime [3].

### A. Dust-dominated background

Let us restrict now, for the sake of example, to a dust-dominated background with \( a(t) = a_0 t^{2/3} \) and \( H(t) = \frac{2}{3t} \). Consider the case \( |Q| < m \). Then eq. (20) can be solved explicitly at different times \( t \) giving the location of the apparent horizons. These are plotted versus comoving time

---

4 Albeit with the addition of the spherical singularity not present in Reissner-Nordström. This spherical singularity is present even when \( |Q| = m \) and independently of the time dependence \( a(t) \), as long as it is not exactly constant. The authors are currently investigating further this curious feature of the charged and uncharged McVitte spacetime.
FIG. 1. The physical radii $R$ of the apparent horizons of the charged McVittie spacetime versus time $t$ for $m = 1$ and $Q = 1/2$ and dust-dominated power law background $a(t) = t^{2/3}$. The blue dash-dotted line is the location of the corrected ‘Hubble radius’ $R = 1/H - m$ which is an asymptote for the largest apparent horizon at late times while the black dashed line is the location of the spherical singularity (11).

in Fig. 1 for a choice of parameters. The phenomenology of these apparent horizons is similar to that found for the uncharged McVittie solution [11, 12, 15, 29].

Initially (near the Big Bang $t = 0$), there are no apparent horizons in the connected outer region beyond the spherical singularity; at a critical time a cosmological and a black hole apparent horizon appear. The black hole apparent horizon shrinks asymptoting to the singularity, while the cosmological apparent horizon expands forever. This phenomenology is interpreted in [15] for $Q = 0$ by noting that at early times the size of the black hole horizon exceeds that of the cosmological horizon and such a large black hole cannot be accommodated in a small universe. (This situation is similar to that of the Schwarzschild-de Sitter black hole, which is a special case of the McVittie metric [15].) Later on, the cosmological horizon becomes larger than the black hole apparent horizon, which now fits below the cosmological horizon [15].

Note that the innermost apparent horizon, which asymptotes to the location of the inner unstable Cauchy horizon of Reissner-Nordström geometry, is located in the inner disconnected region, separated from the exterior geometry by the singularity [11], converging to $R = 0$ at the Big Bang.

B. Universe undergoing finite expansion

As a toy model to further investigate the interesting apparent horizon structures, let us consider a universe undergoing a finite expansion from an initially quasi-static regime to a final quasi-static regime with scale factor

$$a(t) = \frac{a_f + a_i}{2} + \frac{a_f - a_i}{2} \tanh \left( \frac{t}{t_0} \right).$$

(23)

Shown in Fig. 2 is the scale factor (23) for the choice $a_i = 1$, $a_f = 2$, and $t_0 = 1$ representing a universe which expands by a factor of 2 from $t = -\infty$ to $t = +\infty$. We consider only the case $|Q| < m$ for the rest of this subsection and also fix the values $m = 1$ and $Q = 1/2$ for illustration.

The horizon phenomenology in this case depends on the time scale of expansion $t_0$ with horizon mergers and horizon joinings possible. In Fig. 3 we plot the roots of the polynomial (20) over time for a ‘fast’ expansion ($t_0 = 1$) where the cosmological horizon shrinks from $R = +\infty$ to eventually merge with the expanding black hole horizon leaving a naked singularity for a period followed by the birth again of two horizons which separate, the cosmological one out to $R = +\infty$ and the black hole horizon asymptoting to the spherical singularity at $R = m + \sqrt{m^2 - Q^2}$.

Note that the horizon structure is not symmetric about $t = 0$ since it is the asymmetric function $H(t) = \dot{a}/a$ which enters the quartic polynomial defining the horizon locations. In Fig. 4 we plot the location of the apparent
horizons over time for a “slow” expansion \( t_0 = 0.57 \) where the cosmological horizon does not shrink enough to subsume the black hole horizon. In this slow case, the spherical singularity is always hidden behind an apparent horizon for asymptotic observers far from the inhomogeneity.

Interestingly, the curious limiting case in which the cosmological and black hole horizons meet at a point, appearing to intersect, can be solved for exactly, occurring when the Hubble parameter attains a critical value \( H_{\text{crit}} \) at its maximum leaving a single apparent horizon at \( R_{\text{crit}} \) in the exterior region, where

\[
R_{\text{crit}} = \frac{3}{2} m + \frac{1}{2} \sqrt{9m^2 - 8Q^2}, \quad (24)
\]

\[
H_{\text{crit}} = \frac{1}{R_{\text{crit}}} \sqrt{\frac{1}{3} - \frac{Q^2}{3R_{\text{crit}}^2}}, \quad (25)
\]

Such a scenario is shown in Fig. 5 where we see the “crossing” of the horizons at a single time.

C. The extremal case \( |Q| = m \)

In the extremal case with \( |Q| = m \) the quartic relation \( (20) \) is exactly solvable, with solutions

\[
R_{\text{extremal}} := \frac{1}{2H} \pm \frac{\sqrt{1 - 4mH}}{2H}, \quad -\frac{1}{2H} \pm \frac{\sqrt{1 + 4mH}}{2H}. \quad (26)
\]
The extremal case \( |Q| = m \) is interesting in the sense that an explicit analytical expression like (26) for the apparent horizon radii is rare to find in investigations of time-evolving black holes \cite{7}. One of these roots is always negative and hence is discarded

\[
R_{\text{negative}} = -\frac{1}{2H} - \frac{\sqrt{1 + 4mH}}{2H}. \tag{27}
\]

The smallest positive root given by

\[
R_{\text{inner}} := -\frac{1}{2H} + \frac{\sqrt{1 + 4mH}}{2H} \tag{28}
\]

is always present while the other two

\[
R_{\pm} := \frac{1}{2H} \pm \frac{\sqrt{1 - 4mH}}{2H} \tag{29}
\]

can merge (become complex) or appear simultaneously (become real) depending on the evolution of \( H \). Interestingly, for the dust-dominated background \( H \to 0 \) as \( t \to +\infty \) and we see that \( R_{\text{inner}} \) and \( R_{-} \) in fact converge to the same radius \( R = m \). This common limit radius is precisely where the single event horizon of extremal Reissner-Nordström sits, nicely showing that we recover the phenomenology of the static charged spacetime in the appropriate limit. This horizon behaviour is shown in Fig. \( \text{F6} \).

\textbf{D. The supercritical case} \( |Q| > m \)

In the case \( |Q| > m \) we expect a naked singularity, based on the limit of constant \( a \) which reproduces the Reissner-Nordström spacetime. The cosmological horizon is still present, as expected from the previous considerations. In fact, numerical plots for this situation provide a single (cosmological) apparent horizon, as shown in Fig. \( \text{F7} \).

\textbf{III. DISCUSSION}

In the parameter range \( |Q| \leq m \) explored we find only a cosmological apparent horizon and one black hole apparent horizon, while in the Reissner-Nordström black hole (to which the metric reduces if \( a \equiv 1 \)) it is well known that also an inner black hole (apparent) horizon is present. This fact begs the question of why, in the charged McVittie spacetime which generalizes the Reissner-Nordström metric, we do not see an inner black hole horizon in addition to the cosmological horizon. The inner black hole horizon of the Reissner-Nordström black hole is unstable with respect to linear perturbations and the effect of the cosmological “background” on the central inhomogeneity is akin to a non-linear (or exact) “large perturbation”, therefore, the absence of an inner black hole horizon is not too surprising in this regard. We expect such an horizon to be absent in any exact solution of the Einstein equations describing a Reissner-Nordström-like black hole interacting with a non-trivial environment.

\textbf{ACKNOWLEDGMENTS}

This work is supported by Bishop’s University and by the Natural Sciences and Engineering Research Council of Canada.

\footnote{However, this “perturbation” is not “small”, in the sense that it corresponds to an infinite amount of mass-energy added to the Reissner-Nordström spacetime, even in the case of arbitrary-}
FIG. 7. The areal radius of the apparent horizon of the charged McVittie spacetime versus time for $|Q| > m$ in solid red. The dashed blue line is the corrected Hubble radius $R = 1/H - m$ to which the single apparent horizon asymptotes from above at late times motivating its characterisation as a cosmological apparent horizon. There is a naked singularity at $R = 0$.
