ABSTRACT

Approximately 14% of known Galactic open clusters possess absolute errors ≤20% as evaluated from n ≥ 3 independent distance estimates, and the statistics for age estimates are markedly worse. That impedes such diverse efforts as calibrating standard candles and constraining masses for substellar companions. New data from the VVV survey may be employed to establish precise cluster distances with comparatively reduced uncertainties (±10%). This is illustrated by deriving parameters for Pismis 19 and NGC 4349, two pertinent open clusters which hitherto feature sizable uncertainties (60%). Fundamental parameters determined for Pismis 19 from new VVV $JHK_s$ photometry are $d = 2.40 \pm 0.15$ kpc, $(E_J-H) = 0.34 \pm 0.04$, and $log \tau = 9.05 \pm 0.10$, whereas for NGC 4349 the analysis yielded $d = 1.63 \pm 0.13$ kpc, $E_{J-H} = 0.09 \pm 0.02$, $log \tau = 8.55 \pm 0.10$. The results exhibit a significant (≥5×) reduction in uncertainties, and indicate that: i) existing parameters for the substellar object NGC 4349 127b require revision, in part because the new cluster parameters imply that the host is 20% less massive ($M/M_\odot \sim 3.1$); ii) R Cru is not a member of NGC 4349 and should be excluded from period-Wesenheit calibrations that anchor the distance scale; iii) and results for Pismis 19 underscore the advantages gleaned from employing deep VVV $JHK_s$ data to examine obscured $(A_V \sim 4$) and differentially reddened intermediate-age clusters.

Key words. techniques: photometric – Hertzsprung-Russell and C-M diagrams – dust, extinction – stars: distances

1. Introduction

Approximately 30% of the 395 open clusters featuring $n \geq 3$ independent distance estimates exhibit absolute errors ≥20% (Paunzen & Netopil 2006, their Fig. 2). There are $\geq 2 \times 10^3$ cataloged Galactic open clusters (Dias et al. 2002), implying that merely ~14% of the known sample possess errors ≤20% as evaluated from three distance estimates. The uncertainties permeate into analyses which rely on the cluster zero-point, such as the calibration of any constituent standard candles or substellar companions (Lovis & Mayor 2007; Majaess et al. 2011B). Consider that published parameters for NGC 4349 span $d = 900-2200$ pc and $\tau = 0.1-0.6$ Gyr (Sect. 3.2) Yet physical parameters for the substellar companion to TYC 8975-2601-1 (Lovis & Mayor 2007; Kashyap et al. 2008) rely on those inferred for the host from cluster membership (NGC 4349). Furthermore, the nearer age and younger age for NGC 4349 potentially imply cluster membership for the classical Cepheid R Cru, which lies within the cluster’s corona. Establishing cluster membership would enable the subsequent calibration of Cepheid period-luminosity and period-Wesenheit relations (Turner 2010). Such functions bolster efforts to establish extragalactic distances and zero-point the SNe Ia scale (e.g., Pietrzyński & Gieren 2004).

In this study, new VVV (VISTA Variables in the Vía Láctea) $JHK_s$ photometry is employed to illustrate the marked improvement that can be achieved $vis \ à \ vis$ open cluster distances. Two important clusters featuring particularly discrepant published parameters are examined, namely Pismis 19 and NGC 4349. Distances for the clusters display a ~60% spread and individual uncertainties of ~30%. Efforts to secure precise parameters for Pismis 19 via optical photometry have been complicated by differential reddening and $A_V \sim 4$ mag of obscuring dust. Parameters for Pismis 19 and NGC 4349 derived here exhibit a marked (>5×) reduction in uncertainties (Sect. 3), and highlight

the advantages of using VVV data to determine reliable cluster distances and compliment existing efforts.

2. VVV photometry

The VVV survey aims to establish precise multi-epoch $JHK_s$ photometry for fields in the Galactic bulge and near the Galactic plane ($\ell = 295-10^5$, Minniti et al. 2010; Catelan et al. 2011; Saito et al. 2011). VVV images exhibit increased angular resolution relative to 2MASS, and extend $\sim$4 mag fainter for Galactic disk stars. The deep $JHK_s$ photometry facilitates isochrone fitting by revealing the target cluster’s evolutionary morphology, which is particularly important when investigating highly reddened clusters. The VVV survey will provide standardized (2MASS) $JHK_s$ photometry for stars in $\geq 3 \times 10^5$ open clusters and $\geq 39$ globular clusters (e.g., M28). Details of the pipeline constructed to process and extract the VVV photometry employed here are discussed in Mauro et al. (in prep.). PSF photometry was performed using DAOPHOT and subsequently tied to 2MASS $JHK_s$ standards (Fig. 1, see also Moni Bidin et al. 2011). However, as with any nascent large scale survey adjustments to the zero-point may occur as improvements and systematic errors are identified.

2.1. The advantages of $JHK_s$ photometry

Precise $JHK_s$ observations of stellar clusters are desirable since total and differential reddening are less deleterious than in the optical ($A_V \sim 0.2 \times A_J$). Sizable extinction may shift a significant fraction of the main-sequence near/beyond the limiting magnitude where uncertainties are largest. Consider that merely $\lesssim 3''$ of the cluster sequence for Pismis 19 was sampled in existing optical surveys owing to significant reddening, which subsequently complicated efforts to establish the cluster zero-point. The $JHK_s$ reddening vector provides viable solutions for the intrinsic colors of stars across much of the main-sequence. The $JHK_s$ reddening vector can be determined from red clump stars along the line of sight (Straižys & Laugalys 2008; Majaess et al. 2011b), and the ratio of total-to-selective extinction can be inferred in certain instances using red clump stars via the variable extinction method (e.g., Majaess et al. 2011b). Straižys & Laugalys (2008) demonstrated that $E(J-H)/E(H-K_s)$ is (rather) constant for dust occupying the inner Galaxy. A consensus exists that any variations in the infrared would be marginal relative to that expected for the optical.

$JHK_s$ photometry is particularly suited for detecting and characterizing the heavily obscured pre-main-sequence population of young clusters (Bonatto & Bica 2010). For later-type stars, $JHK_s$ photometry is relatively insensitive to variations in chemical composition (e.g., the Hyades anomaly, Turner 1979; Majaess et al. 2011a; see also Straižys & Lazauskaitė 2009). That claim is supported in part by the establishment of seven benchmark open clusters ($d < 250$ pc) which exhibit matching $JHK_s$ ZAMS and revised Hipparcos distances (the Hyades, α Per, Praesepe, Coma Ber, IC 2391, IC 2609, and NGC 2451, van Leeuwen 2009; Majaess et al. 2011a). The zero-point of the Padova isochrone employed (Sect. 3) matches that scale, to within the uncertainties. Isochrones, models, and the distance scale should be anchored (& evaluated) using clusters where consensus exists, rather than the discrepant case (i.e. the Pleiades). The 2MASS survey provides invaluable all-sky $JHK_s$ photometric standards. A similar survey tied to Johnson-Cousins $UBVRI$ photometry is desirable. $U$-band photometry is particularly challenging to standardize and zero-point errors are common (Sect. 3.2, see also Cousins & Caldwell 2001). However, $UBV$ color–color analyses permit crucial dereddening for younger stars.

In summary, the VVV survey is aptly tailored to foster cluster research (Minniti et al. 2011; Borrissova et al. 2011; Moni Bidin et al. 2011; Majaess et al. 2011b). Admittedly, acquiring precise and standardized $UBV$/$JHK_s$ photometry is ideal, and enables the characterization of potential systematic errors. $UBV$ data by Turner/Forbes (unpublished) and Carraro (2011, in press) are employed to corroborate parameters determined via the VVV photometry.

3. Analysis

3.1. Pismis 19

Pismis 19 is a heavily reddened open cluster (Piatti et al. 1998; Carraro & Munari 2004). The cluster’s non-symmetric appearance in optical images is indicative of differential reddening. Piatti et al. (1998) and Carraro & Munari (2004) acquired $BVI$ photometry for Pismis 19 stars. However, separate conclusions were reached regarding the cluster’s fundamental parameters. Piatti et al. (1998) determined the following: $E(B-V) = 1.45 \pm 0.10$, $d = 2.40 \pm 0.88$ kpc, $\tau = 1.0 \pm 0.2$ Gyr, whereas Carraro & Munari (2004) obtained $E(B-V) = 1.48 \pm 0.15$, $d = 1.5 \pm 0.4$, $\tau = 0.8$ Gyr. The reddenings and distances agree within the mutual uncertainties, however, the individual uncertainties are large enough to the challenging task of analyzing highly obscured clusters solely via optical photometry. Carraro (2011) built upon Piatti et al. (1998) and Carraro & Munari (2004) analyses by obtaining deeper photometry, and derived $d = 2.5 \pm 0.5$ kpc.

Individual redenning for stars in Pismis 19 were determined as follows. Any point on the dereddening line (dl) for the $i$th star is given by:

$$ (J-H) = E_{J-H}/E_{H-K_s} \times (H-K_s) + b; \quad b = (J-H) - E_{J-H}/E_{H-K_s} \times (H-K_s); \quad (J-H)_{0} = E_{J-H}/E_{H-K_s} \times (H-K_s)_{0}; \quad (J-H)_{dl} = E_{J-H}/E_{H-K_s} \times (H-K_s)_{dl} + b. $$

The intersect between the dereddening line and the intrinsic relation was determined by minimizing the difference as a function of $(H-K_s_0)_{dl} - (J-H)_{dl}$.

$$ E(J-H)/E(H-K_s) \quad \text{is (rather) constant for dust occupying the inner Galaxy. A consensus exists that any variations in the infrared would be marginal relative to that expected for the optical.}$$
That result agrees with a determination for the region from 2MASS photometry (Straižys & Laugalys 2008). A reddening vector of \( E(J - H) = 0.34 \pm 0.04 \) was adopted based on the reddening and spectral types inferred from the color–color diagram, and since that age provides an evolutionary track which aptly matches both bluer and redder evolved members. NGC 4349 features evolved stars. A precise fit was obtained owing to several factors. First, two of three free parameters associated with isochrone fitting were constrained by the color–color analysis, namely the reddening and age (spectral type at the turnoff). The remaining parameter (excluding metallicity) is the shift required in magnitude space to overlay the isochrone upon the data. The best fit and uncertainties were established via the traditional visual approach. Published reddenings for R Cru (Fernie 1963) are nearly consistent with that inferred for R Cru from present day period-Wesenheit relations (Majaess et al. 2011b). Lindoff (1968) revised the Lohmann (1961) age for NGC 4349 downward to \( \log \tau = 8.04 \). Loktin & Matkin (1994) computed the following properties for NGC 4349 based on a reanalysis of existing photometry: \( d = 2176 \) pc, \( E(B-V) = 0.384 \), and \( \log \tau = 8.315 \). In sum, published parameters for NGC 4349 span \( d = 900 - 2200 \) pc.

A reddening vector of \( E(J - H)/E(H-K_s) = 2.04 \) was determined from red clump stars along the line of sight (see also Straižys & Laugalys 2008). The reddening vector was subsequently adopted to establish a reddening of \( E(J - H) = 0.09 \pm 0.02 \). Stars catalogued by Lohmann (1961) as likely cluster members were employed to derive that result. New photoelectric \( UBV \) photometry\(^2\) obtained for stars in NGC 4349 were likewise used to constrain the cluster reddening, and age. A comparison between that photoelectric \( UBV \) photometry and the photographic photometry of Lohmann (1961) reveals the latter is offset from the standard system: \( B - V = (1.02 \pm 0.02) \times (B - V)_{Loh} - 0.02 \pm 0.02; U - B = (0.96 \pm 0.02) \times (U - B)_{Loh} + 0.09 \pm 0.01; V = (-0.015 \pm 0.03) \times (B - V)_{Loh} + 0.06 \pm 0.02 \times V_{Loh} \). The offset may partly explain the difference between the distances inferred from the \( UBV \) photometry of Lohmann (1961) and the present analysis. Applying an intrinsic \( UBV \) color–color relation to the corrected data yields a reddening of \( E(B-V) = 0.32 \pm 0.03 \). The canonical extinction law was employed, and may be refined once spectroscopic observations are available. Stars in NGC 4349 terminate near B8-A0 according to the intrinsic \( JHK_s \) and \( UBV \) relations (e.g., Straižys & Lazauskaitė 2009; Turner 2011). Published reddenings for R Cru (Fernie 1990) are nearly half that derived for the cluster, implying that the Cepheid lies in the foreground. That is consistent with the Cepheid’s parameters as inferred from the latest period-Wesenheit relations (e.g., Benedict et al. 2007), which indicate that R Cru is less than 1 kpc distant.

A color–magnitude diagram for NGC 4349 is shown in Fig. 3. A log \( \tau = 8.55 \pm 0.10 \) Padova isochrone (Bonatto et al. 2004) was adopted based on the reddening and spectral types inferred from the color–color diagram, and since that age provides an evolutionary track which aptly matches both bluer and redder evolved members. NGC 4349 features evolved stars

---

\(^{1}\) The coordinates cited for the cluster center in simbad require updating.

\(^{2}\) Obtained with the 0.6 m Helen Sawyer Hogg Telescope which was stationed at Cerro Las Campanas, Chile.
Fig. 3. Color–magnitude diagrams constructed for NGC 4349 and an adjacent comparison field using VVV/2MASS $JHK_s$ photometry. The circled dot near the tip of the giant branch is TYC 8975-2606-1, which hosts a substellar companion (Lovis & Mayor 2007). To mitigate contamination the CMDs feature stars within $r < 1.2'$. Seven evolved red stars beyond that radius were added to the CMD for NGC 4349.

brighter than the saturation limit of the VVV survey. Therefore, $JHK_s$ photometry for these stars were taken from 2MASS. The color–magnitude diagram for NGC 4349 was restricted to stars within $\leq 1.2'$ to mitigate field contamination. The final parameters for NGC 4349 are: $d = 1.63 \pm 0.13$ kpc, $E(J-H) = 0.09 \pm 0.02$, and $\log \tau = 8.55 \pm 0.10$. A ratio of total to selective extinction ($R$) was adopted from Majaess et al. (2011b) (see also Bonatto et al., 2004, and references therein).

In their comprehensive survey Lovis & Mayor (2007) discovered that TYC 8975-2606-1 hosts a substellar companion (designated NGC 4349 127b). Lovis & Mayor (2007) adopted cluster parameters of $d = 2200$ pc and $\tau = 200$ Myr, which implied a $3.9 M_\odot$ host. However, the distance and age established here for NGC 4349 are 30% nearer and 150 Myr older, respectively. The parent star exhibits the following parameters according to the Padova isochrone applied: $M_*/M_H \sim 3.1$ and $\log L/L_\odot \sim 2.7$. Yet the principal source of uncertainty hindering a reliable determination of the orbital parameters remains the sparsely sampled radial velocity curve (Lovis & Mayor 2007), as indicated by simulations conducted using the Systemic Console (Meschiari et al. 2009). Nevertheless, a minimum mass for the substellar companion of $M_*/M_J \sim 17$ was obtained. Kashyap et al. (2008) derived an X-ray luminosity for the system in order to evaluate whether giant planets in close proximity to the host are catalysts for magnetic activity. That determination was based on a distance to NGC 4349 of $d = 2176$ pc, thereby reaffirming the importance of establishing a precise distance scale.

4. Conclusion

VVV $JHK_s$ observations may be employed to help establish precise cluster distances that feature comparatively reduced uncertainties ($\leq 10\%$). That is illustrated by deriving fundamental parameters for Pismis 19 and NGC 4349, two important clusters which hitherto exhibit sizable uncertainties (60%, Sects. 3.1 and 3.2). A precise distance determination for Pismis 19 from optical photometry was hampered in part by significant reddening (Fig. 2, $A_V \sim 4$). The existing ambiguity surrounding the distance to NGC 4349 ensured that the pertinence of invaluable putative constituents were mitigated (i.e., the classical Cepheid R Cru and a substellar companion for the member TYC 8975-2601-1). Parameters derived for Pismis 19 are: $d = 2.40 \pm 0.15$ kpc, $E(J-H) = 0.34 \pm 0.04$, $\log \tau = 9.05 \pm 0.10$ (Fig. 2), whereas NGC 4349 exhibits $d = 1.63 \pm 0.10$ kpc, $E(J-H) = 0.09 \pm 0.02$, $\log \tau = 8.55 \pm 0.10$ (Fig. 3). The nature of the VVV survey ensured that the revised results, which have pertinent ramifications, compliment existing estimates and display a marked improvement ($\geq 5\times)$ in precision. New VVV $JHK_s$ for stars in NGC 4349 and Pismis 19 imply that: existing physical parameters derived for NGC 4349 127b need to be re-determined in part since the mass for the host star was revised downward to $M_*/M_H \sim 3.1$ (Sect. 3.2); the classical Cepheid R Cru is not a member of NGC 4349 (Sect. 3.2); and VVV $JHK_s$ photometry is particularly suited for constraining parameters of obscured and differently reddened intermediate-age clusters (e.g., Pismis 19, Fig. 2).

The VVV and UKIDSS surveys (Lucas et al. 2008; Minniti et al. 2010) may be employed to achieve significant gains toward strengthening the open cluster distance scale. However, considerable work remains, and improvements in the pipelines used to process the data are inevitable given the nascent nature of the aforementioned surveys.
