Abstract

Background: Early diagnosis and prompt treatment can save lives of the patients with bladder cancer. The confirmatory test for grade of the disease is histopathological examination after transurethral resection. But if the grade of the tumor can be predicted at the time of presentation from size and number of tumors seen by ultrasonographic imaging, clinician can counsel the patient beforehand and also arrange rapid treatment to save life.

Objective: To assess the size and number of tumors as clinical predictors of histological grade of urothelial carcinoma of urinary bladder before first-time transurethral resection of the bladder tumor (TURBT).

Methods: This cross-sectional study was conducted in the Department of Urology, BSMMU and RGRH from January 2020 to April 2020. Fifty patients were enrolled in this study. Size and number of the tumor was determined by preoperative ultrasonography of urinary bladder. Histopathological examination was used to determine the grade of the tumor after TURBT. Statistical analysis was performed using SPSS version 22.0.

Results: Mean age of the study subjects was 52.04 ± 18.37 years within the range of 22–95 years. Males (56.0%) were predominant than females (44.0%). Male to female ratio was 1.27:1. Mean number of tumor was 1.28 ± 0.64 (1-3) and mean tumor size was 3.54 ± 1.47 cm (1-7). High grade tumor was 26 (52.0%) and low grade tumor was 24 (48.0%). There was no significant association of tumor grading with number of tumor in this study. High grade tumor was significantly higher among the study subjects with tumor size >3.5 cm. Area under curve (AUC) of tumor number and tumor size was 0.558 and 0.827 respectively in prediction of tumor grading. Sensitivity, specificity, PPV, NPV and accuracy of tumor number (at cut of value 3) was 15.4%, 95.8%, 80.0%, 51.1% and 54.0% respectively. Sensitivity, specificity, PPV, NPV and accuracy of tumor size (at cut of value 3.5 cm) was 90.5%, 76.3%, 80.9%, 87.9% and 83.7% respectively. Overall Sensitivity, specificity, PPV, NPV and accuracy of tumor size was better than tumor number in prediction of tumor grading.

Conclusion: According to this study finding, it can be concluded that the grade of newly diagnosed bladder tumors can be predicted with high accuracy using tumor size.

Keywords: TURBT, tumor size, number of tumor.

1. INTRODUCTION

Bladder cancer is the second most common cancer of the genito-urinary tract [1]. It is the 9th most common cancer in the world [2], and is the 13th most common cause of death accounting for 145,000 deaths worldwide [2, 3]. At initial
diagnosis, more than 70% of patients have non-muscle invasive bladder cancer (NMIBC), which is generally treated with (TURBT) with or without intravesical therapy [4]. Bladder carcinoma is highly diverse disease which can be low grade or high grade. Low grade tumors are recurrent but possess less threat to patient’s life. But high grade tumors are potentially fatal as they are highly likely to invade the muscle coat [5,6]. Thus, high-grade is one of the most important factors for predicting a poor clinical outcome in NMIBC. The histological grade of the bladder cancer is eventually determined by examining the resected tumor under microscope after TURBT. The most widely used classification for grading of NMIBC (G1, G2 and G3) was the 1973 World Health Organization (WHO) classification [7]. However, a revised grading system for urothelial carcinoma (UC) (low-grade and high-grade) was proposed and adopted by the WHO in 2004 to replace the 1973 WHO classification system [8]. Urologists often clinically suspects broad based tumors as high grade and pedunculated tumors as low grade. But this is obscure and not greatly supported by data. Also clinicians usually suspects large and multiple tumors to be of high grade. But there is very sparse data to support this. This study is designed to assess the size and number of tumors in the urinary bladder as clinical predictor of histological grade of urothelial carcinoma of urinary bladder before first-time transurethral resection of the bladder tumor (TURBT).

2. OBJECTIVES

General Objective:

a) To assess the size and number of tumors as clinical predictors of histological grade of urothelial carcinoma of urinary bladder before first-time transurethral resection of the bladder tumor (TURBT).

Specific Objective:

a) To determine the size of bladder tumor by ultrasonography (USG).

b) To determine the number of tumors by USG.

c) To determine the grade of the tumor by histopathological examination after TURBT.

d) To compare the size and number of tumor with histological grade.

3. METHODOLOGY

This cross-sectional study was conducted in the Department of Urology, BSMMU and RGRH from January 2020 to April 2020. Fifty patients were enrolled in this study. Size and number of the tumor was determined by preoperative ultrasonography of urinary bladder. Histopathological examination was used to determine the grade of the tumor after TURBT.

Selection Criteria:

Inclusion criteria:

- Patients with detectable bladder tumor by USG.
- No previous history of TURBT.

Exclusion Criteria:

- Patients with Recurrent bladder mass.
- Tumor grossly extending beyond urinary bladder.

Data processing and analysis: Data editing cleaning and reduction was done by taking care for omission and illegal entry of data. After compilation the data were presented in the form of tables and figures as necessary. Statistical analysis was performed using SPSS version 22.0. Quantitative data was tabulated as a mean ± standard deviation and significance was analyzed by using independent sample t-test. Qualitative data was tabulated as frequency & percentage and was compared with Chi-square test. Statistical significance will be set at $P <0.05$.

Ethical consideration: Participation of the respondents in the study was voluntary. Informed consent has been obtained after a brief overview of the study to all the respondents. It has been clarified to them that they have the liberty to refuse or take part in the study. All information will be kept confidential. The interview was conducted at suitable times and interview place which was convenient to the respondents. Due permission has been taken from the particular institution.

Bladder Cancer

Epidemiology of BC: BC is the most common malignancy of the urinary tract, the 7th most common cancer in men and the 17th in women [9]. The worldwide age-standardized incidence rate is 9 per 100,000 for men and 2
Prediction of Grade of Urothelial Carcinoma of Urinary Bladder from the Size and Number of Tumors at First Presentation

per 100,000 for women (2008 data) [10]. In the European Union (EU), the age-standardized incidence rate is 27 per 100,000 for men and 6 per 100,000 for women [12]. The incidence of BC varies between regions and countries; in Europe, the highest age-standardized incidence rate has been reported in Spain (41.5 in men and 4.8 in women) and the lowest in Finland (18.1 in men and 4.3 in women) [10]. Worldwide age-standardized mortality rate is 3 per 100,000 for women. In the EU, the age standardized mortality rate is 8 for men and 3 per 100,000 for women, respectively [12]. In 2008, BC was the eighth most common cause of cancer-specific mortality in Europe [10]. The incidence of BC has decreased in some areas, possibly reflecting the decreased impact of causing agents, mainly smoking and occupational exposure [13]. Mortality from BC has also decreased, possibly reflecting an increased standard of care [11].

Etiology of BC: Tobacco smoking is the most important risk factor for BC, accounting for approximately 50% of the cases, [14,15], because tobacco smoke contains aromatic amines and polycyclic aromatic hydrocarbons, which are renally excreted. Cigarette smokers have a two- to fourfold increased risk of bladder cancer compared with non-smokers [16], and the risk increases with increasing intensity and duration of smoking [20]. On cessation of smoking, the risk of bladder cancer falls >30% after 1–4 years and by >60% after 25 years but never returns to the risk level of non-smokers [12]. Occupational exposure to aromatic amines, polycyclic aromatic hydrocarbons, and chlorinated hydrocarbons is the second most important risk factor for BC, accounting for about 10% of all cases. This type of occupational exposure occurs mainly in industrial plants processing paint, dye, metal, and petroleum products [17,18]. Although the significance of the amount of fluid intake is uncertain, the chlorination of drinking water and subsequent levels of trihalomethanes are potentially carcinogenic, while exposure to arsenic in drinking water increases the risk [14]. Schistosomiasis, a chronic endemic cystitis, based on recurrent infection with a parasitic trematode, is a cause of BC [14]. Finally, there is increased evidence that genetic predisposition may influence the incidence of TCC of the bladder [14], especially via its impact on susceptibility to other risk factors [14,21].

Prognostic Factors (PF) of NMIBC: NMIBC is a heterogeneous group of tumors whose prognosis and therapeutic indications are very difficult to establish at the diagnosis time. Although TURBT is an essential diagnostic tool and an effective treatment for bladder cancer, 45% of patients will have tumor recurrence within 12 months of TURBT alone. Tumor recurrence can be attributed to a combination of missed tumors, incomplete, initial resection, reimplantation of tumor cells after resection, and tumor occurrence in high risk urothelium. Several factors influence the recurrence rate, for instance, clinical and pathological results, applied treatments, and diagnostics. There are two fundamental risks attributed to NMIBC: the risk of recurrence without worsening the grade or stage and the risk of progression to MIBC. So, according to this behavior, basically, NMIBC can be classified into three groups of patients. A minority of patients (20–30%) have a relatively benign type of TCC with a low recurrence rate. These low risk tumors do not show progression. The largest group of patients includes those who frequently develop a NMIBC recurrence but seldom experience progression. A third, small group of patients, includes those who have a relatively aggressive non-muscle invasive tumor at presentation. Despite maximum treatment, up to 45% of these patients will develop MIBC. The desire to predict which NMIBC will become MIBC and will develop disseminated disease has stimulated the study of factors with possible prognostic value; these are called prognostic factors (PF).

4. RESULTS
Mean age of the study subjects was 52.04 ± 18.37 years within the range of 22 – 95 years. Maximum patients were >60 years followed by 51 – 60 years (24.0%), 21 – 30 years (18.0%), 31-40 years (16.0%) and 41 - 50 years (14.0%).

Table1. Distribution of the study subjects according to age (N=50)

| Age (years) | Frequency (n) | Percentage (%) |
|------------|---------------|----------------|
| 21-30      | 9             | 18.0           |

ARC Journal of Urology
Prediction of Grade of Urothelial Carcinoma of Urinary Bladder from the Size and Number of Tumors at First Presentation

Males (56.0%) were predominant than females (44.0%). Male to female ratio was 1.27:1.

Table 2. Distribution of the study subjects according to gender (N=50)

| Gender | Frequency (n) | Percentage (%) |
|--------|---------------|----------------|
| Male   | 28            | 56.0           |
| Female | 22            | 44.0           |

Most of the patients had hematuria (68.0%).

Table 3. Presenting complain of the study subjects (N=50)

| Hematuria     | Frequency (n) | Percentage (%) |
|---------------|---------------|----------------|
| Yes           | 34            | 68.0           |
| No            | 16            | 32.0           |

Fifteen (30.0%) patients had smoking habit.

Table 4. Smoking habit of the study subjects (N=50)

| Smoking | Frequency (n) | Percentage (%) |
|---------|---------------|----------------|
| Yes     | 15            | 30.0           |
| No      | 35            | 70.0           |

Regarding urine R/M/E, mean PUS cell was 9.86 ± 4.81 and mean RBC was 28.02 ± 11.35.

Table 5: Urine R/M/E findings of the study subjects (N=50)

| Urine finding | Frequency (n) | Percentage (%) |
|---------------|---------------|----------------|
| Pus cell      | 9.86 ± 4.81   | 2.00 - 20.00   |
| RBC           | 28.02 ± 11.35 | 5.00 - 45.00   |

Regarding tumor information, mean number of tumor was 1.28 ± 0.64 within the range of 1-3 and mean tumor size was 3.54 ± 1.47 cm within the range of 1 –7 cm.

Table 6: Number and size of the tumors of the study subjects (N=50)

| Tumor information | Frequency (n) | Percentage (%) |
|-------------------|---------------|----------------|
| Number of tumor   | 1.28 ± 0.64   | 1 – 3          |
| Size of tumor     | 3.54 ± 1.47   | 1.00 - 7.00    |

Figure 1 shows ROC curves of tumor number and tumor size in predicting tumor grading. According to ROC curves tumor size showed better Area Under Curve (AUC) than tumor number in predicting tumor grading.

Table 7 shows AUC of tumor number and tumor size in prediction of tumor grading. Area under curve (AUC) of tumor number and tumor size was 0.558 and 0.827 respectively in prediction of tumor grading.

Table 7. AUC of tumor number and tumor size in prediction of tumor grading

| Variable | Area | SE  | p-value | 95% CI Lower Bound | 95% CI Upper Bound |
|----------|------|-----|---------|-------------------|--------------------|
| Number of tumor | 0.558 | 0.082 | 0.485 | 0.398 | 0.718 |
| Size of tumor    | 0.827 | 0.059 | 0.000 | 0.711 | 0.943 |

According to Youden index best cut off value of tumor number is 3 in predicting tumor grading.

Table 8. Youden index of tumor number in prediction of tumor grading (N=50)

| Number of tumor | Sensitivity | Specificity | Youden Index |
|-----------------|-------------|-------------|--------------|
| 1               | 1.000       | 0.900       | 0.000        |
| 2               | 0.231       | 0.875       | 0.106        |
| 3               | 0.154       | 0.958       | 0.112        |
| 4               | 0.000       | 1.000       | 0.000        |

According to Youden index best cut off value of tumor size is 3.50 cm in predicting tumor grading.

Table 9. Youden index of tumor size in prediction of tumor grading (N=50)

| Tumor size | Sensitivity | Specificity | Youden Index |
|------------|-------------|-------------|--------------|
| 1.50       | 1.000       | 0.903       | 0.083        |
| 2.50       | 0.885       | 0.942       | 0.426        |
| 3.50       | 0.769       | 0.972       | 0.561        |
| 4.50       | 0.500       | 0.917       | 0.417        |
| 5.50       | 0.115       | 1.000       | 0.115        |
| 6.50       | 0.077       | 1.000       | 0.077        |
| 8.00       | 0.000       | 1.000       | 0.000        |
The use of ultrasonography involves detrusor ion [24]. Regarding tumor grading (N=50) NPV of tumor number and tumor size in prediction of tumor grading. Sensitivity, specificity, PPV, NPV and accuracy of tumor size was better than tumor number (at cut of value 3) was 90.5%, 80.9%, 87.9% and 83.7% respectively. Overall Sensitivity, specificity, PPV, NPV and accuracy of tumor size (at cut of value 3.5 cm) was 90.5%, 80.9%, 87.9% and 83.7% respectively. Table 12 shows sensitivity, specificity, PPV and NPV of tumor number and tumor size in prediction of tumor grading (N=50).

**Table 10. Association of tumor grading with tumor number at cut off value 3 (N=50)**

| Number of tumors | Grading of tumor | Total | p-value  |
|------------------|-----------------|-------|---------|
|                  | High grade      | Low grade |       |
| ≥3               | 4 (15.4)        | 1 (4.2) | 5 (10.0) | 0.351 |
| <3               | 22 (84.6)       | 23 (95.8) | 45 (90.0) |       |
| Total            | 26 (100.0)      | 24 (100.0) | 50 (100.0) |       |

Fisher’s Exact test was done to measure the level of significance

Table 11 shows association of tumor grade with tumor size at cut off value 3.5. High grade tumor was significantly higher among the study subjects with tumor size >3.5 cm.

**Table 11. Association of tumor grade with tumor size at cut off value 3.5 (N=50)**

| Size of tumor (cm) | Grade of tumor | Total  | p-value |
|--------------------|---------------|--------|---------|
|                    | High grade    | Low grade |       |
| >3.5               | 20 (76.9)     | 5 (20.8) | 25 (50.0) | <0.001 |
| ≤3.5               | 6 (23.1)      | 19 (79.2) | 25 (50.0) |       |
| Total              | 26 (100.0)    | 24 (100.0) | 50 (100.0) |       |

Chi-Square test was done to measure the level of significance

Table 12 shows sensitivity, specificity, PPV and NPV of tumor number and tumor size in prediction of tumor grading. Sensitivity, specificity, PPV, NPV and accuracy of tumor number (at cut of value 3) was 15.4%, 95.8%, 80.0%, 51.1% and 54.0% respectively. Sensitivity, specificity, PPV, NPV and accuracy of tumor size (at cut of value 3.5 cm) was 90.5%, 76.3%, 80.9%, 87.9% and 83.7% respectively. Overall Sensitivity, specificity, PPV, NPV and accuracy of tumor size was better than tumor number in prediction of tumor grading.

**Table 12. Sensitivity, specificity, accuracy, PPV and NPV of tumor number and tumor size in prediction of tumor grading (N=50)**

| Tumor | Cut off value | Sensitivity | Specificity | PPV | NPV | Accuracy |
|-------|---------------|-------------|-------------|-----|-----|----------|
| Number| 3             | 15.4        | 95.8        | 80.0| 51.1| 54.0     |

5. DISCUSSION

Bladder cancer is the second most common cancer of the genito-urinary tract. Urothelial carcinoma can be High grade and low grade according to WHO criteria. Low grade disease usually is not life threatening though frequently recurrent and less frequently involves detrusor muscle and deeper tissues. But high-grade disease is a potentially fatal disease which frequently invades detrusor muscle and beyond. Timely cystectomy can save lives but that requires early diagnosis and prompt treatment. The confirmatory test for grade of the disease is histopathological examination after transurethral resection. But if the grade of the tumor can be predicted at the time of presentation from size and number of tumors seen by ultrasonographic imaging, clinician can counsel the patient beforehand and also arrange rapid treatment to save life. Mean age of the study subjects was 52.04 ± 18.37 years within the range of 22–95 years. Males (56.0%) were predominant than females (44.0%). Male to female ratio was 1.27:1. Mean age was 66.1±14.3 years and male to female ratio was 4.19:1 in the study of Shapur et al. [5]. Most of the patients had hematuria (68.0%). Fifteen (30.0%) patients had smoking habit. Regarding urine R/M/E, mean PUS cell was 9.86 ± 4.81 and mean RBC was 28.02 ± 11.35 in this study. The use of ultrasonography for the diagnosis of bladder cancer is well established since the early 1980s [22, 23]. It is a very sensitive modality for tumors greater than 0.5 cm with almost 100% detection rate independent of their location [24]. Regarding tumor information, mean number of tumor was 1.28 ± 0.64 (1-3) and mean tumor size was 3.54 ± 1.47 cm (1-7) in this study. Mean number of tumor was 1.16± 0.5 and mean size of tumor was 2.5± 1.4 in the study of Shapur et al. [5]. In this study, high grade 26 (52.0%) tumor was and low grade tumor was 24 (48.0%). In the study of Shapur et al. [5], high grade tumor was 169 (39.2%) and low grade tumor was (60.8%). There was no significant association of tumor grading with number of tumor in this study. The number of tumors on ultrasound was not related to the risk of high-grade tumors [5]. High grade tumor was significantly higher among the study subjects with tumor size >3.5 cm. The risk of a high-grade tumor was 14, 29, 43.3, 55.7 and 69.4% at the tumor size 0.5–1.5, 1.6–2, 2.1–2.5, 2.6–3 and 13.1 cm, respectively [5]. Area under...
curve (AUC) of tumor number and tumor size was 0.558 and 0.827 respectively in prediction of tumor grading. Sensitivity, specificity, PPV, NPV and accuracy of tumor number (at cut of value 3) was 15.4%, 95.8%, 80.0%, 51.1% and 54.0% respectively. Sensitivity, specificity, PPV, NPV and accuracy of tumor size (at cut of value 3.5 cm) was 90.5%, 76.3%, 80.9%, 87.9% and 83.7% respectively. Overall Sensitivity, specificity, PPV, NPV and accuracy of tumor size was better than tumor number in prediction of tumor grading.

6. CONCLUSION

According to this study finding, it can be concluded that the grade of newly diagnosed bladder tumors can be predicted with high accuracy using tumor size but number of tumor cannot be used as predictor of high grade tumor.
