REAL ROOTS IN THE ROOT SYSTEM $T_{2,p,q}$

KARIN BAUR, JIAN-RONG LI, AND ANDREI SMOLENSKY

ABSTRACT. Motivated by the recent advances in the categorification of the cluster structure on the coordinate rings of Grassmannians of $k$-subspaces in $n$-space, we investigate a particular construction of root systems of type $T_{2,p,q}$, including the type $E_n$. This construction generalizes Manin’s “hyperbolic construction” of $E_8$ and reveals a lot of otherwise hidden regularities in this family of root systems.

1. INTRODUCTION

The real roots of root systems of finite, affine and hyperbolic type can be characterized in terms of the coefficients of their decomposition into the linear combination of simple roots [Kac, Proposition 5.10]. For the root system with a simply-laced diagram this description boils down to the following: the real roots are the elements of the root lattice having the same norm as the simple roots. However, for non-hyperbolic root systems this condition is only necessary, but not sufficient. There is at present no general description of real roots available for non-hyperbolic root systems.

We investigate the root system of type $J_{k,n} = T_{2,k,n-k}$, $k \leq n$, which has the following diagram:

\[ \alpha_1 \quad \alpha_2 \quad \alpha_k \quad \alpha_{k+1} \quad \alpha_{n-1} \]

Here we denote $\beta = \alpha_n$. The root system $J_{3,n}$ is usually called the $E_n$ root system, while $J_{1,n} = A_n$ and $J_{2,n} = D_n$. In general, the root system $J_{k,n}$ is non-finite, non-affine, and non-hyperbolic. With this paper, we give a characterization of real roots for a large class of root systems.

Such root systems appear naturally in the study of generalized Del Pezzo varieties, that is, roughly speaking, the blow-ups of $\mathbb{P}^n$ at some finite set of points, see [Coble, DO]. In particular, for the case $k = 3$ and its relation to the Picard lattice of Del Pezzo surfaces see [Manin, Section 25].

Another motivation for the present paper is the study of the rigid indecomposable modules in Grassmannian cluster categories $\text{CM}(B_{k,n})$, see [JKS, BBG] and cluster variables in Grassmannian cluster algebras $\mathbb{C}[\text{Gr}_{k,n}]$ [Scott]. Cluster algebras are a class of commutative rings introduced by S. Fomin and A. Zelevinsky in their series of foundational papers [BFZ, FZ1, FZ2, FZ3] (the paper [BFZ] is with coauthor A. Berenstein). Scott proved that there is a cluster algebra structure on the coordinate ring $\mathbb{C}[\text{Gr}_{k,n}]$ of the Grassmannian varieties $\text{Gr}_{k,n}$. Jensen, King and Su in [JKS]
showed that the category $\text{CM}(B_{k,n})$ of Cohen-Macaulay modules over a quotient $B_{k,n}$ of a preprojective algebra of affine type $A$ provides an additive categorification of $\mathbb{C}[\text{Gr}_{k,n}]$ and they showed that there is a cluster character on $\text{CM}(B_{k,n})$ which sends rigid indecomposable modules to cluster variables in $\mathbb{C}[\text{Gr}_{k,n}]$. They proved these results by showing that the quotient of this category by a single projective-injective object is Geiss-Leclerc-Schroer’s category $\text{Sub}_{Q_k}$ [GLS] which categorifies the coordinate ring of the big cell in the Grassmannian $\text{Gr}(k, n)$. In their paper, the authors associated the root system $J_{k,n}$ to $\text{CM}(B_{k,n})$. They pointed out that rigid indecomposable modules in $\text{CM}(B_{k,n})$ seem to correspond to (real or imaginary) roots of $J_{k,n}$. Thus studying the roots of $J_{k,n}$ will help to study the rigid indecomposable modules in Grassmannian cluster categories $\text{CM}(B_{k,n})$ [JKS] and cluster variables in Grassmannian cluster algebras $\mathbb{C}[\text{Gr}_{k,n}]$ [Scott].

In this paper, we give a characterization of the real positive roots in the root system $J_{k,n}$. A real positive root $\gamma \in J_{k,n}$ is said to have degree $d$ if when $\gamma$ is written as a linear combination of simple roots, the coefficient of $\beta$ in $\gamma$ is $d$. Degree 0 positive roots are just positive roots of the natural root subsystem of type $A_{n-1}$ given by the nodes $\alpha_1, \ldots, \alpha_{n-1}$. They are all of the form $\alpha_i + \cdots + \alpha_{j-1}$ for some $1 \leq i < j \leq n$.

In an arbitrary root system there is a procedure to check whether a positive element of the root lattice is a real root: for a positive real root there exists a sequence of simple reflections which at each step lowers the height (and eventually leads to a simple root), see [Kac, Proposition 5.1(e)]. However, there is no systematic way to find this sequence other than by trial and error.

Our main result is that if one realizes the root lattice $\mathbb{Z}\Delta$ as a sublattice of $\mathbb{Z}^n$ (see Section 2), then in terms of the ambient lattice the above procedure can be done much faster and easier, as follows.

**Theorem 2.10.** $x = (x_1, \ldots, x_n)^\top \in \mathbb{Z}\Delta$ is a positive real root of degree $\geq 1$ if and only if

1. $0 \leq x_i \leq \text{deg}(x)$ for all $i = 1, \ldots, n$,
2. $q(x) = 2$,
3. repeated application of $x \mapsto s_\beta(\text{dec}(x))$ preserves property (1) until it changes the sign of all entries of $x$.

Here $q(x)$ is a quadratic form (2.1) on $\mathbb{Z}^n$, $s_\beta$ is the simple reflection associated with $\beta$, $s_\beta \left( (x_1, \ldots, x_n)^\top \right) = (x_1 + r, \ldots, x_k + r, x_{k+1}, \ldots, x_n)^\top$, $r = x_{k+1} + \cdots + x_n - 2 \text{deg}(x)$, $\text{deg}(x) = \frac{1}{k} \sum_{i=1}^{n} x_i$, and $\text{dec}(x) \in \mathbb{Z}\Delta$ is the element obtained from permuting the entries of $x_i$ to have them in decreasing order, i.e. if $\text{dec}(x) = (x'_1, \ldots, x'_n)$ then $x'_1 \geq x'_2 \geq \cdots \geq x'_n$.

The procedure in Theorem 2.10 allows a very efficient enumeration of real roots. This enumeration reveals many regularities which are otherwise harder to see. Among other things, it provides another view on Manin’s “hyperbolic construction” of $E_8$, which can be seen as the inclusion $E_8 \subset J_{4,9}$. This also highlights the connection between the affine roots of $E_9$ inside $J_{4,10}$ and the exceptional curves on del Pezzo surfaces.
Jensen, King and Su conjectured [JKS] that for every indecomposable module $M$ in $\text{CM}(B_{k,n})$, there is a corresponding real or imaginary root $\varphi(M)$ (see Section 6 for the definition of $\varphi(M)$) in the root system $J_{k,n}$. It is conjectured in [BBGL, Conjecture 5.8] that whenever $M$ in $\text{CM}(B_{k,n})$ is rigid indecomposable and $\varphi(M)$ is a real root in $J_{k,n}$, then the profile $P_M$ (a profile is a certain array of integers, see Section 6 for the definition) is a cyclic permutation of a canonical profile. The results about real roots in $J_{k,n}$ in Theorem 2.10 are thus expected to help with the characterization of rigid indecomposable modules in $\text{CM}(B_{k,n})$ corresponding to real roots.

The paper is organized as follows. In Section 2 we construct the root lattice and the action of the Weyl group on it, and give a characterization of real roots. In Section 3 we note various relations between the root systems $J_{k,n}$ for distinct $k, n$. Section 4 is devoted to the enumeration of real roots and to some particular families of real roots. In 4.2 we discuss the finite types, i.e. the types $A_n, D_n, E_6, E_7$ and $E_8$ and give a simple description of the fundamental weights. Section 4.3 provides a simpler description of isotropic roots in root systems of affine types $J_{3,9} = E_8^{(1)}$ and $J_{4,8} = E_7^{(1)}$. Also, in Section 4.4 we introduce the notion of “almost real roots”. These are not roots but closely resemble the real roots. Section 5 compares the description given in the present paper with Manin’s “hyperbolic construction” of $E_8$. Section 6 describes in greater details the connection to the cluster structures on the coordinate rings of Grassmannians mentioned above.

Acknowledgments. We would like to thank Alastair King for very helpful discussions. We also thank the anonymous referee for their work and for their helpful comments. 2. Real roots in $J_{k,n}$ root system

2.1. Root lattice. Jensen, King, and Su gave a description of the root system $J_{k,n}$ [JKS, Section 2]. This description of the root system arises naturally as the lattice that grades the Grassmannian cluster algebra $\text{Gr}_{k,n}$. They observed that, for the right quadratic form $q(x)$ there seems to be a relationship between cluster variables and positive degree roots. We recall their results in the following.

Let $n$ and $k < n$ be two natural numbers and let $e_1, \ldots, e_n$ be the standard basis of $\mathbb{R}^n$. Let

$$\alpha_i = e_{i+1} - e_i \quad \text{for} \quad i = 1, \ldots, n - 1, \quad \beta = e_1 + \ldots + e_k,$$

and consider the lattice

$$\mathbb{Z}\Delta = \langle \beta, \alpha_1, \ldots, \alpha_{n-1} \rangle_{\mathbb{Z}} = \{(x_1, \ldots, x_n)^\top \in \mathbb{Z}^n \mid k \text{ divides } x_1 + \ldots + x_n\},$$
called the **root lattice** and equipped with the quadratic form
\[
q(x) = \sum_{i=1}^{n} x_i^2 + \frac{2-k}{k^2} \left( \sum_{i=1}^{n} x_i \right)^2.
\] (2.1)

and an inner product given by its polarization \((x, y) = \frac{1}{2} (q(x+y) - q(x) - q(y))\).

Any element \(\alpha \in \mathbb{Z} \Delta\) can be written as \(\alpha = m_\beta \beta + m_1 \alpha_1 + \ldots + m_{n-1} \alpha_{n-1}\), and the coefficient \(m_\beta\) is called the **degree** of \(\alpha\), denoted by \(\deg(\alpha)\). If \(x = (x_1, \ldots, x_n)^\top \in \mathbb{Z} \Delta\), then
\[
\deg(x) = (x_1 + \ldots + x_n)/k \quad \text{and} \quad q(x) = x_1^2 + \ldots + x_n^2 + (2-k) \deg(x)^2.
\]

A direct calculation shows that the inner products are \((\alpha_i, \alpha_i) = 2\) for \(i = 1, \ldots, n-1\) and \((\beta, \beta) = 2\) and that
\[
(\alpha_i, \alpha_j) = \begin{cases} -1, & \text{if } |i-j| = 1, \\ 0, & \text{otherwise,} \end{cases} \quad (\beta, \alpha_i) = \begin{cases} -1, & \text{if } i = k, \\ 0, & \text{otherwise.} \end{cases}
\]

so that the Gram matrix \(A\) of this inner product with respect to the basis \(\beta, \alpha_1, \ldots, \alpha_{n-1}\) is the generalized Cartan matrix of the root system of type \(J_{k,n}\).

The matrix of the basis change from \(\{\beta, \alpha_1, \ldots, \alpha_{n-1}\}\) to \(\{e_1, \ldots, e_n\}\) is
\[
C = \begin{pmatrix}
1 & -1 & \vdots & \vdots & \vdots & \vdots \\
1 & 1 & -1 & \vdots & \vdots & \vdots \\
\vdots & \ddots & \ddots & \ddots & \vdots & \vdots \\
1 & 1 & \cdots & \cdots & -1 & 0 \\
0 & \ddots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & \ddots & \ddots & \ddots & 1 \\
0 & \cdots & \cdots & \cdots & \cdots & 1
\end{pmatrix}.
\]

Therefore if
\[
\gamma = m_\beta \beta + m_1 \alpha_1 + \ldots + m_{n-1} \alpha_{n-1},
\]
then
\[
\gamma = x_1 e_1 + \ldots + x_n e_n,
\]
where
\[
(x_1, \ldots, x_n)^\top = C \cdot (m_\beta, m_1, \ldots, m_{n-1})^\top.
\]

The inverse for \(C\) is calculated as \(C^{-1} = VDU\), where \(V\) is the lower triangular matrix that differs from the identity matrix only in its first column, which equals
\[
(1, 1-k, 2-k, \ldots, -1, 0, \ldots, 0)^\top,
\]
\(D = \text{diag}(\frac{1}{k}, 1, \ldots, 1)\), and \(U\) is an upper triangular matrix having 1 in all of its entries on and above the diagonal. Now
\[
U x = (x_1 + \ldots + x_n, x_2 + \ldots + x_n, \ldots, x_n)^\top,
\]
so the first entry equals $kd$, where $d$ is the degree of $x$. Thus the first entry of $DUx$ equals $d$, and the same holds for $V DUx$.

For the other entries of $V DUx$, note that $x_i + \ldots + x_n$ can be rewritten as $kd - x_1 + \ldots - x_{i-1}$. Thus for $i = 2, \ldots, k$ the $i$-th entry of $V DUx$ equals 

$$(kd - x_1 + \ldots - x_{i-1}) + (i - k - 1)d = (i - 1)d - x_1 + \ldots - x_{i-1}.$$ 

In particular, for $i = k$ it is 

$$(k - 1)d - x_1 + \ldots - x_{k-1} = x_k + \ldots + x_n - d.$$ 

For $i > k$ the $i$-th entry is the same as the $i$-th entry of $Ux$, that is, $x_i + \ldots + x_n$.

Many standard notions can be directly expressed in terms of the $e_i$ basis. For example, if $\gamma = d\beta + \sum m_i\alpha_i$, the scalar product $(\beta, \gamma) = 2d - m_k$ can be computed as $2d - (x_{k+1} + \ldots + x_n)$.

**Example 2.1.** We demonstrate how the correspondence between the two bases described above works in the second simplest case, that is in the case $k = 2$ and $J_{k,n} = D_n$. In $D_n$ the roots of degree 1 are of one of the following three forms (written in the $e_i$'s on the left and in terms of the simple roots on the right):

$$
e_1 + e_j \quad \mapsto \quad \begin{array}{cccc}
0 & 1 & 1 & \ldots & 1 \\
1 & & & & 0 \\
& & & & \ddots \\
& & & & j - 1
\end{array} \quad \text{with } 2 \leq j \leq n - 1,$$

$$
e_2 + e_j \quad \mapsto \quad \begin{array}{cccc}
1 & 1 & 1 & \ldots & 1 \\
1 & & & & 0 \\
& & & & \ddots \\
& & & & j - 1
\end{array} \quad \text{with } 3 \leq j \leq n - 1,$$

$$
e_i + e_j \quad \mapsto \quad \begin{array}{cccc}
1 & 2 & 2 & \ldots & 2 \\
1 & i - 1 & \ddots \\
& & & \ddots \\
& & & & j - 1
\end{array} \quad \text{with } 3 \leq i < j \leq n - 1.$$

So in this case, the description of the positive roots in terms of the $e_i$'s coincides (up to the ordering of the simple roots) with the standard realization [Bou1, Ch. VI, §4, no. 8]: the positive roots of $D_n$ are 

$$(e_i \pm e_j) \quad \text{with } 1 \leq i < j \leq n.$$ 

and the simple roots are

$$\alpha_i = e_{i+1} - e_i, \quad 1 \leq i \leq n - 1, \quad \beta = e_1 + e_2.$$ 

Note that in [Bou1, Ch. VI, §4, no. 8] the numbering of the simple roots is reversed, and $\beta$ is attached to $\alpha_{n-2}$.

**2.2. Weyl group action.** For $i = 1, \ldots, n - 1$ denote by $s_i$ the involution on $\mathbb{Z}^n$ induced by the transposition $(i, i + 1)$ on the basis $e_1, \ldots, e_n$, and its restriction on $\mathbb{Z}\Delta$. Denote also by $s_\beta$ the linear map

$$x = (x_1, \ldots, x_n)^\top \mapsto (x_1 + r, \ldots, x_k + r, x_{k+1}, \ldots, x_n)^\top,$$

where $r = x_{k+1} + \ldots + x_n - 2\deg(x)$. The map $s_\beta$ acts on $\mathbb{Z}\Delta$, indeed, if $x \in \mathbb{Z}\Delta$, then

$$(x_1 + r) + \ldots + (x_k + r) + x_{k+1} + \ldots + x_n = \sum x_i + kr$$

is also divisible by $k$, and $\deg(s_\beta x) = \deg(x) + r$. 

Lemma 2.2. The above formulas define an action of the Weyl group $W(J_{k,n})$ on $\mathbb{Z}\Delta$.

Proof. To show that the action of $s_\beta, s_1, \ldots, s_n$ define an action of the Weyl group, it is enough to show that they satisfy the defining relations of $W(J_{k,n})$ in its standard presentation as a Coxeter group, that is

\begin{align*}
s_\beta^2 &= s_1^2 = \ldots = s_{n-1}^2 = \text{id}, \\
s_is_js_i &= s_js_is_j \quad \text{for} \quad |i - j| = 1, \quad i, j \leq n - 1, \\
s_is_j &= s_js_i \quad \text{for} \quad |i - j| > 1, \quad i, j \leq n - 1, \\
s_\beta s_ks_\beta &= s_ks_\beta, \\
s_\beta s_i &= s_is_\beta \quad \text{for} \quad i \neq k.
\end{align*}

Note that the relations not involving $s_\beta$ are satisfied because $s_1, \ldots, s_{n-1}$ are defined as the fundamental transpositions, which are known to be the standard Coxeter generators of the permutation group $S_n$ [Wilson, Section 2.8.1].

Now set $x = (x_1, \ldots, x_n) \in \mathbb{Z}\Delta$. Then

\begin{align*}
x \xmapsto{s_\beta} (x_1 + r, \ldots, x_k + r, x_{k+1}, \ldots, x_n) \xmapsto{s_\beta} (x_1 + r + r', \ldots, x_{k} + r + r', x_{k+1}, \ldots, x_n),
\end{align*}

where $r = x_{k+1} + \ldots + x_n - 2 \deg(x)$ and $r' = x_{k+1} + \ldots + x_n - 2 \deg(s_\beta x)$. But $\deg(s_\beta x) = \deg(x) + r$, hence $r' = r - 2r$, so $s_\beta^2(x) = x$.

The commutation relation for $s_\beta$ and $s_i$, $i \neq k$ are obvious from the definition.

To prove the braiding relation for $s_\beta$ and $s_k$ consider

\begin{align*}
x \xmapsto{s_k} (x_1, \ldots, x_{k-1}, x_{k+1}, x_k, x_{k+2}, \ldots, x_n) \\
\xmapsto{s_\beta} (x_1 + r, \ldots, x_{k-1} + r, x_{k+1} + r, x_k, x_{k+2}, \ldots, x_n) \\
\xmapsto{s_k} (x_1 + r, \ldots, x_{k-1} + r, x_k, x_{k+1} + r, x_{k+2}, \ldots, x_n),
\end{align*}

where $r = x_k + x_{k+2} + \ldots + x_n - \deg(x)$, and

\begin{align*}
x \xmapsto{s_\beta} (x_1 + t, \ldots, x_k + t, x_{k+1}, \ldots, x_n) \\
\xmapsto{s_k} (x_1 + t, \ldots, x_{k-1} + t, x_{k+1} + t, x_k + t, x_{k+2}, \ldots, x_n) \\
\xmapsto{s_\beta} (x_1 + t + t', \ldots, x_{k-1} + t + t', x_{k+1} + t', x_k + t, x_{k+2}, \ldots, x_n),
\end{align*}

where $t = x_{k+1} + \ldots + x_n - 2 \deg(x)$ and $t' = x_k + t + x_{k+2} + \ldots x_n - 2 \deg(s_k s_\beta x)$. But $\deg(s_k s_\beta x) = \deg(x) + t$, so $t' = x_k - x_{k+1}$. Thus $r = t + t'$, and also $x_{k+1} + t' = x_k$ and $x_k + t = x_{k+1} + r$, which means that $s_k s_\beta s_k(x) = s_\beta s_k s_\beta(x)$.

$\square$

Lemma 2.3. $W(J_{k,n})$ acts on $\mathbb{Z}\Delta$ by isometries, that is, $q(wx) = q(x)$ for any $w \in W(J_{k,n})$.

Proof. The quadratic form $q$ is invariant under the action of $s_i$, because $q$ is defined in terms of symmetric polynomials. Concerning the action of $s_\beta$, denote $r = x_{k+1} + \ldots + x_n -
Proposition 1. be chosen to be a sequence of reflections which only increase the height, see [Moody, x = h,

Remark 2.4. This action is faithful and coincides with the standard action of W(J_{k,n}) on the root lattice.

Proof. Straightforward check for the action of the generators on the simple roots. □

2.3. Real roots and degree change. The set of real roots \( \Delta_{re} \) of the root system \( \Delta \) is defined as the union of the Weyl group orbits of its simple roots. Since \( J_{k,n} \) is simply-laced, all simple roots lie in the same orbit, and so \( \Delta_{re} = W(J_{k,n})\beta \). Recall that in the basis \( e_1, \ldots, e_n \) one has \( \beta = (1, \ldots, 1, 0, \ldots, 0) \).

The set of positive real roots is denoted by \( \Delta_{re}^+ \).

Remark 2.5. Real roots of degree 0 form a subsystem of type \( A_{n-1} \) and are of the form \( e_i - e_j, i \neq j \). The root \( e_i - e_j \) is positive if \( i > j \).

Lemma 2.6. If \( x = (x_1, \ldots, x_n)^\top \in \Delta_{re}^+ \) and \( \deg(x) = d \geq 1 \), then \( 0 \leq x_i \leq d \) for all \( i = 1, \ldots, n \).

Proof. Induction by \( \deg(x) \).

Consider first the case \( \deg(x) = 1 \). This means that \( x_1 + \ldots + x_n = k \). On the other hand, for a real root \( x \) one has \( q(x) = 2 \). But

\[
q(x) = \sum x_i^2 + \frac{2 - k}{k^2}k^2 = \sum x_i^2 + 2 - k,
\]

hence \( x_1^2 + \ldots + x_n^2 = k \). It follows that all \( x_i \) are either 0 or 1 (otherwise \( \sum x_i^2 > \sum x_i \)).

Now if \( x \in \Delta_{re} \) has \( \deg(x) > 1 \), then there is \( y \in \Delta_{re}^+ \) such that \( \deg(y) < \deg(x) \) and \( x = w(y) \) for some \( w \in W(A_4) \). The assumption \( \deg(y) < \deg(x) \) holds because \( w \) can be chosen to be a sequence of reflections which only increase the height, see [Moody, Proposition 1].

Since \( w = \sigma_1s_{\beta_2} \ldots s_{\beta_m} \sigma_m \) for some \( \sigma_1, \ldots, \sigma_m \in W(A_{n-1}) \cong S_n \), one can replace \( y \) by \( \sigma_2s_{\beta} \ldots \sigma_m(y) \) and \( x \) by \( \sigma_1^{-1}(x) \), so that \( x = s_{\beta}(y) \).

Now \( y = s_{\beta}(x) = (x_1 + r, \ldots, x_{k} + r, x_{k+1}, \ldots, x_n)^\top \) with \( r < 0 \), and \( \deg(y) = \deg(s_{\beta}x) = \deg(x) + r \). By the induction hypothesis, \( 0 \leq x_i + r \leq \deg(y) \) for \( i = 1, \ldots, k \), and \( 0 \leq x_i \leq \deg(y) \) for \( i > k \), so \( 0 \leq x_i \leq \deg(x) \) for all \( i \). □
Remark 2.7. For $x \in \mathbb{Z} \Delta$, which is not a real root, the inequalities $0 \leq x_i \leq \deg(x)$ are only guaranteed to be preserved by $s_\beta$ in case this action increases the degree. That is, if $0 \leq x_i \leq \deg(x)$, $\deg(x) > 0$ and $0 < \deg(s_\beta(x)) < \deg(x)$, then $s_\beta(x)$ can have negative entries or entries greater than its degree. See Section 4.4 for examples.

We will now establish some conditions on $x \in \mathbb{Z} \Delta$ which guarantee that $s_\beta$ lowers the degree of $x$.

Lemma 2.8. If $x = (x_1, \ldots, x_n)^\top \in \mathbb{R}^n$ and $d \in \mathbb{R}$ satisfy
\[
d \geq x_1 \geq \ldots \geq x_n \geq 0, \\
x_1 + \ldots + x_n = kd,
\]
\[
q(x) = \sum x_i^2 + (2 - k)d^2 > 0,
\]
then $x_{k+1} + \ldots + x_n < 2d$.

Proof. The statement of the lemma can be reformulated as follows. Consider the polyhedron $P$ given by the inequalities
\[
P = \left\{ x \in \mathbb{R}^n \mid \begin{array}{c}
d \geq x_1 \geq \ldots \geq x_n \geq 0, \\
x_{k+1} + \ldots + x_n \geq 2d, \\
x_1 + \ldots + x_n = kd
\end{array} \right\}.
\]
One has to show that $P$ lies in a closed ball of radius $d \sqrt{k - 2}$ centered at the origin.

Note that by scaling everything down $d$ times it is sufficient to prove this statement for $d = 1$. Note also that the maximal distance from 0 over all points of $P$ is attained at one of its vertices.

Denote by $A$ the following $(n+2) \times n$ matrix, by $b$ the following column vector in $\mathbb{R}^{n+2}$ and by $c$ the following row vector in $\mathbb{R}^n$:
\[
A = \begin{pmatrix}
1 \\
-1 & 1 \\
\vdots & \vdots & \ddots \\
-1 & 1 \\
0 & \ldots & -1 & 1 & \ldots & -1
\end{pmatrix}, \quad b = \begin{pmatrix}
1 \\
0 \\
\vdots \\
0 \\
-2
\end{pmatrix}, \quad c = (1, \ldots, 1),
\]
so that $P = \{ x \in \mathbb{R}^n \mid Ax \leq b, \ c \cdot x = k \}$.

Denote also by $A(i,j,l)$ the square matrix of the form $\begin{pmatrix} A_I, & * \\ * & c \end{pmatrix}$, where $A_I$ is the submatrix of $A$ consisting of rows with indices in $I = \{1, \ldots, n\} \setminus \{i,j,l\}$. Finally, denote by $b(i,j,l) = \begin{pmatrix} b_I \\ k \end{pmatrix}$.

Then the vertices of $P$ are those points of $P$ which satisfy the equation
\[
A(i,j,l)x = b(i,j,l),
\]
where $1 \leq i < j < l \leq n + 2$ are such that $A(i,j,l)$ is non-singular.
First note that $i \leq k$. Indeed, if $i > k$, then $A(i,j,l)$ contains the first $i$ rows of $A$. The equation coming from $A_{1,*}$ implies $x_1 = 1$, while the next $i-1$ equations mean that $x_1 = x_2 = \ldots = x_i$, so $x_1 + \ldots + x_n \geq x_1 + \ldots + x_i = i > k$.

Note also that $i,j,l$ cannot all be simultaneously $\leq k+1$, because there is a linear dependence between the rows from $k+2$ to $n+2$, namely,

$$A_{k+2,*} + 2A_{k+3,*} + 3A_{k+4,*} + \ldots + (n-k)A_{n+1,*} = A_{n+2,*}.$$

Assume first that $l = n+2$. Then $j \geq k+1$, because otherwise $x_{k+1} = \ldots = x_n = 0$ and thus $x_{k+1} + \ldots + x_n < 2$. The solution is of the form

$$x = \left(\overbrace{1,\ldots,1}^{i-1}, \overbrace{y,\ldots,y}^{j-i}, 0,\ldots,0\right), \quad y = \frac{k+1-i}{j-i}.$$

Since $j \geq k+1$, the inequalities of the form $x_s \geq x_{s+1}$ are also satisfied. Now $x_{k+1} + \ldots + x_n = y \cdot (j - k - 1)$.

Let $s = k+1-i$, so that $y = \frac{s}{j-i}$. If $x$ is a vertex, then

$$x_{k+1} + \ldots + x_n = y \cdot (j - k - 1) \geq 2,$$

or, equivalently,

$$\frac{s}{j-i}(j-i-s) \geq 2.$$

The squared distance from the origin to $x$ equals

$$x_1^2 + \ldots + x_n^2 = (i-1) + (j-i)y^2 = (i-1) + \frac{(k+1-i)^2}{j-i} = k - s + \frac{s^2}{j-i} = k + \frac{s}{j-i}(s+i-j) \leq k-2.$$

Now assume that $l < n+2$. Then the solution is of the form

$$x = \left(\overbrace{1,\ldots,1}^{i-1}, \overbrace{y_1,\ldots,y_1}^{j-i}, \overbrace{y_2,\ldots,y_2}^{l-j}, 0,\ldots,0\right).$$

The values of $y_1$ and $y_2$ are subject to the following two equations. The first one is

$$x_1 + \ldots + x_n = k, \quad i.e. \quad (i-1) + y_1 \cdot (j-i) + y_2 \cdot (l-j) = k.$$

The form that the equation $x_{k+1} + \ldots + x_n = 2$ takes depends on $j$.

If $j \leq k+1$, the second equation is $y_2 \cdot (l-k-1) = 2$. In this case

$$y_2 = \frac{2}{l-k-1}, \quad y_1 = \frac{(k+1-i)(l-k-1) + 2(j-l)}{(l-k-1)(j-i)}.$$

Write

$$s = k+1-i, \quad t = k+1-j, \quad r = l-k-1,$$

so that

$$y_1 = \frac{sr - 2(t+r)}{r(s-t)}, \quad y_2 = \frac{2}{r}.$$
The inequality $y_2 \leq y_1$ can be reformulated as $2(s + r) \leq sr$, while the inequality $y_1 \leq 1$ means $rt \leq 2(t + r)$. Now
\[
x_1^2 + \ldots + x_n^2 = k - s + (s - t)\frac{(sr - 2(t + r))^2}{r^2(s - t)^2} + (t + r)\frac{4}{r^2}.
\]
This sum being not greater than $k - 2$ can be expressed as
\[
2 - s + \frac{(sr - 2(t + r))^2}{r^2(s - t)} + \frac{4(t + r)}{r^2} \leq 0,
\]
or, multiplying by $r^2(s - t)$,
\[
(2 - s)(s - t)r^2 + (sr - 2(t + r))^2 + 4(t + r)(s - t) \leq 0.
\]
But the left-hand side can be rewritten as
\[
(sr - 2(s + r)) \cdot (rt - 2(t + r)),
\]
which is non-positive.

If $j > k + 1$, the second equation becomes $y_1 \cdot (j - k - 1) + y_2 \cdot (l - j) = 2$. This system of equations is equivalent to
\[
\begin{pmatrix}
j - i & l - j \\
i - k - 1 & 0
\end{pmatrix}
\begin{pmatrix}
y_1 \\
y_2
\end{pmatrix}
= \begin{pmatrix}
k + 1 - i \\
i - k + 1
\end{pmatrix},
\]
thus
\[
y_1 = \frac{i - k + 1}{i - k - 1}, \quad y_2 = \frac{(k + 1 - i)(i - k - 1) + (i - j)(i - k + 1)}{(i - k - 1)(l - j)}.
\]
Again, write
\[
s = k + 1 - i, \quad t = j - k - 1, \quad r = l - k - 1,
\]
so that
\[
y_1 = \frac{s - 2}{s}, \quad y_2 = \frac{s^2 + (s + t)(2 - s)}{s(r - t)} = \frac{2(s + t) - st}{s(r - t)}.
\]
The inequalities $0 \leq y_2 \leq y_1$ are equivalent to $st \leq 2(s + t)$ and $sr \geq 2(s + r)$. Now
\[
x_1^2 + \ldots + x_n^2 = k - s + (s + t)\frac{(s - 2)^2}{s^2} + (r - t)\frac{(2(s + t) - st)^2}{s^2(r - t)^2},
\]
and this sum being not greater than $k - 2$ is equivalent to
\[
(2 - s)(r - t)s^2 + (s + t)(s - 2)^2(r - t) + (2(s + t) - st)^2 \leq 0.
\]
The left-hand side can be rewritten as
\[
(st - 2(s + t)) \cdot (sr - 2(s + r)),
\]
which is non-positive. \qed

Denote by $\text{dec}(x) \in \mathbb{Z}^\Delta$ the permutation of entries of $x = (x_1, \ldots, x_n)^\top$ such that $x_1 \geq x_2 \geq \ldots \geq x_n$.

**Corollary 2.9.** If $x \in \Delta_{re}^+$ is such that $x = \text{dec}(x)$, then $\deg(s_\beta x) < \deg(x)$. 
Proof. The entries of the real root \( x = (x_1, \ldots, x_n)^\top \) satisfy the assumptions of the Lemma 2.8, so \( \deg(s_\beta x) = \deg(x) + x_{k+1} + \ldots x_n - 2 \deg(x) < \deg(x) \). \qed

Theorem 2.10. \( x = (x_1, \ldots, x_n)^\top \in \mathbb{Z}\Delta \) is a positive real root of degree \( \geq 1 \) if and only if

1. \( 0 \leq x_i \leq \deg(x) \) for all \( i = 1, \ldots, n \),
2. \( q(x) = 2 \),
3. repeated application of \( x \mapsto s_\beta(\text{dec}(x)) \) preserves property (1) until it changes the sign of all entries of \( x \).

Proof. For any real root \( x \) with \( \deg(x) \geq 1 \), all three properties are satisfied, because they are satisfied for \( \beta = (1, \ldots, 1, 0, \ldots, 0)^\top \) and are preserved by the operation \( x \mapsto s_\beta(\text{dec}(x)) \) by Lemmas 2.3 and 2.6 and Corollary 2.9.

Now assume that \( x \in \mathbb{Z}\Delta \) satisfies these three properties, and consider the sequence

\[
(x^{(i)})_{i \in \mathbb{Z}_{\geq 0}} \quad \text{with} \quad x^{(0)} = x, \quad x^{(i+1)} = s_\beta(\text{dec}(x^{(i)})).
\]

By Lemma 2.8 \( \deg(x^{(i+1)}) < \deg(x^{(i)}) \). Denote by \( m \) the smallest index such that \( x^{(m)} \) has non-negative entries but \( x^{(m+1)} \) only has non-positive entries. Then \( \text{dec}(x^{(m)}) \) is of the form \( (y_1, \ldots, y_k, 0, \ldots, 0)^\top \) for some non-negative \( y_i \), because \( s_\beta \) only affects the first \( k \) entries and must change the signs of all entries by property (3).

Denote \( d = \deg(x^{(m)}) \), so that by property (3) \( y_i \leq d \). Now since \( (y_1 + \ldots + y_k)/k = d \), it follows that \( y_i = d \) and \( \text{dec}(x^{(m)}) = (d, \ldots, d, 0, \ldots, 0)^\top \). But then

\[
q(\text{dec}(x^{(m)})) = kd^2 + (2 - k)d^2 = 2d^2,
\]

so by property (2) \( d = 1 \) and \( \text{dec}(x^{(m)}) = \beta \) (and \( x^{(m+1)} = -\beta \)). This implies that \( x \in W\beta \) and hence it is a real root. \qed

Remark 2.11. It follows from the proof of the above theorem that property (3) can be replaced by the following: repeated application of \( x \mapsto s_\beta(\text{dec}(x)) \) leads to \( -\beta \), and it does so in at most \( \deg(x) \) steps (in particular, for a real root \( x \) of degree 1 one has \( \text{dec}(x) = \beta \) and \( s_\beta(\text{dec}(x)) = -\beta \)).

Remark 2.12. The process described above also works for the elements of the root lattice close to the real roots. In particular, it allows to distinguish non-roots admitting a sequence of height-lowering simple reflections, see Section 4.4. The latter are related to the indecomposable modules appearing in the categorification of Grassmannian cluster algebras, see Section 6.

3. Symmetries and Embeddings

There is a natural correspondence between \( J_{k,n} \) and \( J_{n-k,n} \) as their graphs are isomorphic, i.e. they have the same root system, with a different ordering of the simple roots.

Remark 3.1. If \( x = (x_1, \ldots, x_n)^\top \) is an element of the root lattice \( J_{k,n} \), then the corresponding element of the root lattice \( J_{n-k,n} \) is \( x' = (d - x_n, \ldots, d - x_1)^\top \), where \( d = \deg(x) \).
Proof. This correspondence is linear, maps simple roots to simple roots in symmetric positions and preserves the quadratic form:

\[ q_{n-k,k}(x') = \sum (d - x_i)^2 + (2 - (n - k))d^2 \]
\[ = nd^2 - 2d \cdot \sum x_i + \sum x_i^2 + (2 - n + k)d^2 \]
\[ = \sum x_i^2 - 2kd^2 + (2 + k)d^2 = q_{k,n}(x). \quad \square \]

The root system \( J_{k,n} \) can be considered as a subsystem of both \( J_{k,n+1} \) and \( J_{k+1,n+1} \) in the natural way, meaning that the branch node of the tree is mapped to the branch point of the larger graph. In terms of the \( \alpha \), \( \beta \), we can consider any positive root for a larger system containing it. The next remark explains how the subsystem arises in terms of the \( x_i \)'s.

Remark 3.2. If \( x = (x_1, \ldots, x_n)^\top \) is an element of the root lattice \( J_{k,n} \) of degree \( d \), then the corresponding elements of the root lattices \( J_{k,n+1} \) and \( J_{k+1,n+1} \) are

\[ (x_1, \ldots, x_n, 0)^\top \quad \text{and} \quad (d, x_1, \ldots, x_n)^\top, \]

respectively. Note that both have degree \( d \) in their respective root lattice.

Proof. Both correspondences are linear, map simple roots to the respective simple roots and preserve the quadratic form:

\[ d^2 + \sum x_i^2 + (2 - (k + 1))d^2 = \sum x_i^2 + (2 - k)d^2. \quad \square \]

In particular, iterating the above, this provides a description of the infinite rank root system \( J_{\infty,\infty} \) as a set of \( \mathbb{Z} \)-indexed sequences \((x_i)_{i \in \mathbb{Z}}\) of integers such that there exists \( M \in \mathbb{N} \) such that

1. \( (x_{-M}, \ldots, x_M)^\top \) is an element of \( J_{M,2M+1} \) of degree \( d \),
2. \( x_{M+1} = x_{M+2} = \ldots = 0 \),
3. \( x_{-M-1} = x_{-M-2} = \ldots = d \).

Note that the particular choice of such \( M \) does not change the degree \( d \). Indeed, if \( x_{-M} + \ldots + x_M = Md \), then \( x_{-M-m} + \ldots + x_{M+m} = (M + m)d \).

This naturally extend to the description of the infinite rank root lattice \( \mathbb{Z}J_{\infty,\infty} \). It is equipped with the inner product \( q \) defined as the value of \( q \) on \( \mathbb{Z}J_{M,2M+1} \) for a suitable \( M \).

We also define \( \text{dec}(x) \) as follows: for \((x_i)_{i \in \mathbb{Z}} \in \mathbb{Z}J_{\infty,\infty} \) with \( x_i \geq 0 \) and of degree \( d \) denote \( x' = \text{dec} \left( (x_{-M}, \ldots, x_M)^\top \right) \in \mathbb{Z}J_{M,2M+1} \) and set \( \text{dec}(x) \) to be the image of \( x' \) in \( \mathbb{Z}J_{\infty,\infty} \). Note that if \( x \) is a real root of \( J_{\infty,\infty} \), then so is \( \text{dec}(x) \).

For every \( x \in \mathbb{Z}J_{\infty,\infty} \) there exist the smallest \( k, n \) such that \( x \) comes from an element of \( \mathbb{Z}J_{k,n} \) by means of Remark 3.2. Namely, \( k \) is the smallest natural number such that \( x_{-k-1} = x_{-k-2} = \ldots = \text{deg}(x) \), while \( n \) is the smallest such that \( x_{n-k} = x_{n-k+1} = \ldots = 0 \).
4. Enumeration of roots

4.1. Real roots. In order to enumerate roots, we can use the action of the $A_{n-1}$ type subsystem in $J_{k,n}$ as explained in the following remark.

**Remark 4.1.** The Weyl group $W(A_{n-1}) \cong S_n$ of the root subsystem $\langle \alpha_1, \ldots, \alpha_{n-1} \rangle$ of type $A_{n-1}$ acts on the root lattice by permutations on the entries of $x$ while keeping the degree. Thus the enumeration of roots reduces to the enumeration of the orbits of this action on the roots of each degree. This will be our strategy in this section. In each such orbit we choose one representative which is ordered. This representative has the smallest height over its orbit, and since the support of a root is connected, this root belongs to a particular natural subsystem of the smallest rank.

All orbits of real roots of degrees up to 5 (assuming $k$ and $n$ are large enough) are listed in Table 1, in the coordinates $(x_i)_i$. The completeness of this table is justified by the following lemma.

**Lemma 4.2.** If $x \in \mathbb{Z}J_{\infty,\infty}$ has degree $d \geq 1$, all its entries are non-negative, $q(x) > 0$ and $x = \text{dec}(x)$, then it is a root lattice element of the natural $J_{2d-1,4d-2}$ subsystem.

**Proof.** There are minimal $k, n$ such that $x$ is a root lattice element of a natural $J_{k,n}$ subsystem. Write $x$ in terms of the simple roots for this subsystem. Denote by $m_i$ the coefficient of $\alpha_i$ in $x$, so that $x = m_1\beta + m_1\alpha_1 + \ldots + m_{n-1}\alpha_{n-1}$. Then $m_k = (VDUx)_{k+1} = x_{k+1} + \ldots + x_n$, which by Lemma 2.8 is at most $2d - 1$. It follows that $m_1, \ldots, m_k$ is a strictly increasing sequence, while $m_k, \ldots, m_{n-1}$ is strictly decreasing. Thus $k, n - k \leq 2d - 1$, so $n \leq 4d - 2$. \hfill $\square$

The above lemma gives a tool to enumerate the real roots of degree $\leq d$ as follows:

1. enumerate all length $4d-2$ decreasing sequences of numbers from $\{0, 1, \ldots, d\}$ such that the sum of entries is divisible by $2d - 1$;
2. for each such sequence check whether $q$ evaluates to 2;
3. if it does, perform the procedure of Theorem 2.10 to establish whether this sequence correspond to a real root.

**Remark 4.3.** Since $x = \text{dec}(x)$, the sequences $m_1, \ldots, m_k$ and $m_k, \ldots, m_{n-1}$ are convex in the sense that $2m_i \leq m_{i-1} + m_{i+1}$ for $i = 2, \ldots, k - 1$ and $k + 1, \ldots, n - 2$.

**Remark 4.4.** Experimental evidence suggests that in fact such $x$ is an element of a natural $J_{k,n}$ subsystem for some $n \leq 2d + 2$ and some $k$. The roots $\gamma_d$ and $\delta_d$ (see below) display the extreme cases with $n = 2d + 2$ and $k = 3$ and $k = d + 1$ respectively.

The rest of Section 4 is devoted to the description of particular series of roots. We will show that in terms of the $e_i$'s even the structure of finite type root systems is more transparent.

We start with marking two distinguished families of roots, one in each degree $d \geq 2$:

$$\gamma_d = \underbrace{d \ldots d}_{k-3} \underbrace{d - 1 1 \ldots 1}_{2d+1}$$  \hfill (D)

$$\delta_d = \underbrace{d \ldots d}_{k-d-1} \underbrace{d - 1 \ldots d - 1 1 \ldots 1}_{2d+1}$$  \hfill (E)
corresponding respectively to
\[ \gamma_d = \begin{bmatrix} 1 & d & 2d-1 & 2d-2 & \cdots & 2 & 1 \end{bmatrix} \quad \text{and} \quad \delta_d = \begin{bmatrix} 1 & 2 & \cdots & d & d+1 & d & \cdots & 2 & 1 \end{bmatrix}. \]

The family of roots dual to \( \gamma_d \) (see Remark 3.1) are marked by (D') in Table 1.
Among the roots of these series are $\gamma_2 = \delta_2$, the maximal root of the natural $E_6$ subsystem, and $\delta_3 = \beta + \delta_{4,8} \in J_{4,8}$, see Section 4.3. Their inner products are

\[(\gamma_d, \gamma_d') = 2 - |d - d'|, \quad (\delta_d, \delta_d') = 2 - |d - d'|, \quad (\gamma_d, \delta_d) = d(3 - d).\]

To see that they are indeed real roots note that the sum of last $n - k$ entries of $\gamma_d$ equals $2d - 1$, thus $(\gamma_d, \beta) = 1$ and

\[s_\beta(\gamma_d) = \frac{d - 1}{k-3} \ldots \frac{d - 1}{2} \frac{2001 \ldots 1}{d - 1} \in W(A_{n-1})\gamma_{d-1}.\]

Similarly, the sum of the last $n - k$ entries of $\delta_d$ equals $d + 1$, so $(\delta_d, \beta) = d - 1$ and

\[s_\beta(\delta_d) = \frac{1}{k-1} \ldots \frac{1}{d+1} \frac{10 \ldots 1}{d+1} \in W(A_{n-1})\beta.\]

4.2. Root systems of finite types. Let us now consider the case of finite root systems $J_{3,n} = E_n$, $n = 6, 7, 8$. It can be seen in Table 1 that in $E_6$ and $E_7$ there are no degree 3 roots (as in these cases, $\sum x_i < 3k$). In $E_6$ there is a single degree 2 root $(1,1,1,1,1,1)^\top$, which is the maximal root $\gamma_2$. In $E_7$ there are 7 such roots, all conjugate under $W(A_7)$ to the image of $\gamma_2$ in $E_7$ and of the form $\text{dec}(x) = (1,1,1,1,1,1,0)^\top$. In $E_8$ there is a single $W(A_7)$-orbit of degree 3 roots, of the form $\text{dec}(x) = \gamma_3 = (2,1,1,1,1,1,1)^\top$.

In Fig. 1 the positive roots of $E_6$ are displayed by means of the weight diagram of its adjoint representation. The weight diagram of a representation is a graph with vertices corresponding to the weights of the representation (with multiplicities). An edge labeled $i$ joins the weights $\lambda$ and $\mu$ if $\lambda - \mu = \pm \alpha_i$. The weights of the adjoint representation are the roots of the root system together with zero weights corresponding to the simple roots. To determine the root $\alpha$ corresponding to a given vertex one can find a path joining this vertex to a zero weight and going from left to right. Then $\alpha = \sum \alpha_i$, where sum is taken over all labels $i$ occurring in this path. For more details concerning weight diagrams see [PSV].

Another instance where the $e_i$ basis reveals more symmetry is the expression for the fundamental weights. Recall that by definition fundamental weights (of a simply-laced root system) form the basis dual to the basis of the fundamental simple roots. The expansion of the fundamental weights in terms of the simple roots can be obtained by taking the columns of the matrix $A^{-1}$, the inverse of the Cartan matrix. Thus the expressions in terms of the $e_i$ basis can be calculated as the columns of $CA^{-1}$.

In case $k = 2$ (so that $J_{2,n} = D_n$) this gives (after the renumbering of the simple roots, see Example 2.1) the standard description [Bou1, Ch. VI, §4, no. 8(VI)]

\[\varpi_\beta = \frac{1}{2} (1, \ldots, 1)^\top,\]

\[\varpi_1 = \frac{1}{2} (-1, 1, \ldots, 1)^\top,\]

\[\varpi_i = e_{i+1} + \ldots + e_n \quad \text{for} \quad 2 \leq i \leq n - 1.\]

The fundamental weights for $E_6$, $E_7$ and $E_8$ are listed in Tables 2 to 4.
Figure 1. Weight diagram of the adjoint representation of $E_6$. Only the part corresponding to the positive roots and to zero weights is shown. The rightmost vertices correspond to the zero weights numbered by the simple roots, and all other vertices correspond to positive roots of $E_6$. In any square (parallelogram) the labels on opposite sides coincide and thus some of them are omitted. The vertices of degree 1 roots are labeled by $abc$, meaning that the corresponding roots is $e_a + e_b + e_c$. The leftmost vertex corresponds to $\gamma_2 = e_1 + e_2 + \cdots + e_6$. 
Table 2. Fundamental weights of E_6.

| ϖ | 1 2 3 2 1 | (1, 1, 1, 1, 1)^T |
|---|---|---|
| ϖ_1 | 1/3 \(\begin{pmatrix} 4 & 5 & 6 & 4 & 2 \\ 3 \end{pmatrix} \) | 1/3 \((-1, 2, 2, 2, 2)^T \) |
| ϖ_2 | 1/3 \(\begin{pmatrix} 5 & 10 & 12 & 8 & 4 \\ 6 \end{pmatrix} \) | 1/3 \((1, 1, 4, 4, 4)^T \) |
| ϖ_3 | 2 4 6 4 2 | (1, 1, 2, 2, 2)^T |
| ϖ_4 | 1/3 \(\begin{pmatrix} 4 & 8 & 12 & 10 & 5 \\ 6 \end{pmatrix} \) | 1/3 \((2, 2, 2, 2, 5, 5)^T \) |
| ϖ_5 | 1/3 \(\begin{pmatrix} 2 & 4 & 6 & 5 & 4 \\ 3 \end{pmatrix} \) | 1/3 \((1, 1, 1, 1, 1, 4)^T \) |

Similarly, the sum of all positive roots, which equals twice the sum of the fundamental weights, is

\[
D_n: \quad (0, 1, \ldots, n - 1)^T, \\
E_6: \quad (3, 4, 5, 6, 7, 8)^T, \\
E_7: \quad (15, 17, 19, 21, 23, 25, 27)^T, \\
E_8: \quad (22, 23, 24, 25, 26, 27, 28, 29)^T.
\]

4.3. **Affine roots and roots coming from affine subsystems.** Among the root systems of type J_{k,n} there are two affine type root systems, namely, for \((k, n) = (3, 9)\)
or \((4, 8)\) (there is also \(J_{6,9} \cong J_{3,9}\)). In a simply-laced affine root system \(\Phi\) roots come in families of the form \(\alpha + m\delta\), where \(\alpha\) is a root of the canonical finite type subsystem \(\Phi\) and \(\delta = \delta_{k,n}\) is the smallest element-wise positive vector such that \(A\delta = 0\) for \(A\) the Cartan matrix of \(\Phi\), and \(m \in \mathbb{Z}\).

Denote by \(J\) the \(n \times n\)-matrix consisting of 1’s, so that the Gram matrix of the inner product with respect to the basis \(e_1, \ldots, e_n\) equals \(I - \frac{k^2 - 2}{k^2} J\). On the other hand, it must be equal to \(C^{-\top}AC^{-1}\), so \(A\delta = 0\) implies \(C^{\top}C\delta = \frac{k^2 - 2}{k^2} C^{\top}JC\delta\), which, in turn, means that \(\delta' = C\delta\) satisfies \(\delta' = \frac{k^2 - 2}{k^2} J\delta'\). If \(\delta' = (x_1, \ldots, x_n)^\top\), then \(x_1 = \ldots = x_n = x\) and \(x = k^2 - 2 n x\). There are only three positive integer solutions to \(n = \frac{k^2}{k^2 - 2}\), namely, \((k, n) = (3, 9), (4, 8)\) or \((6, 9)\). Recall that the element \(x\) must also satisfy the restriction that \(\sum x_i = nx\) is divisible by \(k\). In cases \((k, n) = (3, 9)\) and \((4, 8)\) the minimal such \(x\) equals 1, and for \((k, n) = (6, 9)\) one has \(x = 2\). Thus

\[
\delta_{3,9}' = (1, 1, 1, 1, 1, 1, 1, 1)^\top, \quad \delta_{4,8}' = (1, 1, 1, 1, 1, 1, 1)^\top, \quad \delta_{6,9}' = (2, 2, 2, 2, 2, 2, 2, 2)^\top,
\]

which correspond, respectively, to

\[
\delta_{k,n} = \begin{pmatrix} 2 & 4 & 6 & 5 & 4 & 3 & 2 & 1 \\ 3 & 2 & 3 & 4 & 3 & 2 & 1 & 1 \end{pmatrix}, \quad \delta_{4,8} = \begin{pmatrix} 1 & 2 & 3 & 4 & 3 & 2 & 1 \\ 2 & 3 & 4 & 5 & 6 & 4 & 2 \end{pmatrix}, \quad \delta_{6,9} = \begin{pmatrix} 2 & 4 & 6 & 5 & 4 & 3 & 2 & 1 \\ 3 & 2 & 3 & 4 & 3 & 2 & 1 & 1 \end{pmatrix}.
\]

One can consider \(\delta_{k,n}'\) as an element of a larger root system by means of Remark 3.2, and below we will use such identifications implicitly. One also can obtain \(\delta_{6,9}'\) from \(\delta_{3,9}'\) by Remark 3.1.
This means that if \( k \geq 3 \) and \( n - k \geq 6 \), there are the following families of roots in \( J_{k,n} \), coming from the natural \( J_{3,9} \) subsystem:

\[
\pm (e_i - e_j) + m \delta_{3,9} \quad \text{for} \quad k - 3 \leq j < i \leq k + 5, \\
\pm 1 \ldots 1 + m \delta_{3,9} = 3m \pm 1 \ldots 3m \pm 1 \ldots m \pm 1 \ldots m. \quad \text{(A0)}
\]

\[
\pm 2 \ldots 1 \ldots 1 + m \delta_{3,9} = 3m \pm 2 \ldots 3m \pm 2 \ldots m \pm 1 \ldots m. \quad \text{(A1)}
\]

\[
\pm 3 \ldots 3 \ldots 2 \ldots 1 + m \delta_{3,9} = 3m \pm 3 \ldots 3m \pm 2 \ldots m \pm 1. \quad \text{(A2)}
\]

In Table 1 the orbits that contain the roots from one of the series (A0–A3) are marked by \((X_i^\pm)\), with the sign corresponding to the choice of the signs in the formula.

Note that the roots of \((A1^\pm)\) and \((A2^\pm)\) families represent the same \( W(A_{n-1}) \)-orbits, but with different numbering. Namely, the root of \((A1)\) family with a given value of \( m = m_1 \) and + as the sign and the root of \((A2)\) family with \( m = m_1 + 1 \) and − as the sign are obtained from one another by a permutation of the last 9 non-zero entries. The root of the form \((A1)\) with \( m = m_1 \) and − as the sign is in the same \( W(A_{n-1}) \)-orbit as the root of the form \((A2)\) with \( m = m_1 - 1 \) and + for the sign.

The same holds for \((A3^+)\) and \((A3^-)\).

Similarly if \( k \geq 6 \) and \( n - k \geq 3 \), there are roots coming from the natural \( J_{6,9} \) subsystem:

\[
\pm (e_i - e_j) + m \delta_{6,9} \quad \text{for} \quad k - 5 \leq j < i \leq k + 3, \\
\pm 1 \ldots 1 + m \delta_{6,9} = 3m \pm 1 \ldots 3m \pm 12m \pm 1 \ldots 2m \pm 2m. \quad \text{(B0)}
\]

\[
\pm 2 \ldots 1 \ldots 1 + m \delta_{6,9} = 3m \pm 2 \ldots 3m \pm 22m \pm 2 \ldots 2m \pm 2m. \quad \text{(B1)}
\]

\[
\pm 3 \ldots 3 \ldots 1 \ldots 2 \ldots 1 + m \delta_{6,9} = 3m \pm 3 \ldots 3m \pm 32m \pm 3 \ldots 2m \pm 2m. \quad \text{(B2)}
\]

Again, the roots of \((B1^\pm)\) and \((B2^\pm)\) and \((B3^+)\) and \((B3^-)\) represent the same \( W(A_{n-1}) \)-orbits, but with different numbering.

If \( k, n - k \geq 4 \), there are roots coming from the natural \( J_{4,8} \) subsystem:

\[
\pm (e_i - e_j) + m \delta_{4,8} \quad \text{for} \quad k - 4 \leq j < i \leq k + 3, \\
\pm 1 \ldots 1 + m \delta_{4,8} = 2m \pm 1 \ldots 2m \pm 1 \ldots m \pm 1 \ldots m. \quad \text{(C0)}
\]

\[
\pm 2 \ldots 2 \ldots 2 \ldots 1 \ldots 1 + m \delta_{4,8} = 2m \pm 2 \ldots 2m \pm 2 \ldots 2m \pm 2 \ldots 2m. \quad \text{(C1)}
\]

\[
\pm 3 \ldots 3 \ldots 2 \ldots 2 \ldots 2 \ldots 1 \ldots 1 + m \delta_{4,8} = 3m \pm 3 \ldots 3m \pm 32m \pm 3 \ldots 2m \pm 2 \ldots 2m. \quad \text{(C2)}
\]

Here \( W(A_{n-1}) \)-orbits do not depend on the signs (after a suitable renumbering), and, moreover, the orbits of \((C0)\) and \((C2)\) cover the same set of roots.
4.4. Almost real roots. Every real root of degree \( \geq 1 \), when expressed in basis \( e_1, \ldots, e_n \), say, \( x = (x_1, \ldots, x_n)^\top \), satisfies the following three properties by Lemmas 2.3 and 2.6:

1. \( x \in \mathbb{Z}\Delta \),
2. \( 0 \leq x_1, \ldots, x_n \leq d \), where \( d = (x_1 + \ldots + x_n)/k \),
3. \( q(x) = \sum x_i^2 + \frac{2-k}{k^2}(\sum x_i)^2 = 2 \).

However, there are vectors \( x \) satisfying all of the above, which are not real roots. We call such elements of the root lattice almost real roots. They exist in degrees \( \geq 4 \).

Almost real roots of degrees 4 and 5 (in \( J_{k,n} \) for large enough \( k, n \)) are listed in Table 5. Note that the statement of Lemma 4.2 also holds for almost real roots.

| Degree | Almost Real Roots |
|--------|------------------|
| 4      | \( 4 \cdots 4 \) \( \underbrace{3 3 3 3}_{k-4} 1 \cdots 1 \) \( 4 \cdots 4 \) \( \underbrace{3 3 3 3}_{k-6} 1 1 1 1 \) |
| 5      | \( 5 \cdots 5 \) \( \underbrace{3 3 3 3}_{k-3} 1 1 1 \) \( 5 \cdots 5 \) \( \underbrace{4 4 4 4}_{k-4} 1 1 1 1 \) \( 5 \cdots 5 \) \( \underbrace{4 4 4 4}_{k-5} 1 1 1 1 \) |

Table 5. \( W(A_{n-1}) \)-orbits of almost real roots of degrees 4 and 5.

Calculating the minimal subsystems for each orbit of almost real roots in Table 5 we see that degree 4 almost real roots are present in all root systems of type \( J_{k,n} \) which contain \( J_{4,10} \) or \( J_{6,10} \), and that every \( J_{k,n} \) root system containing \( J_{3,11} \) or \( J_{8,11} \) has an almost real root of degree 5. This implies that in every non-finite, non-affine, non-hyperbolic root system of type \( J_{k,n} \) there are almost real roots.

Let \( x \) be a positive almost real root, and assume that \( x = \text{dec}(x) \). Then repeating the operation \( x \mapsto \text{dec}(s_\beta(x)) \) lowers the height and eventually leads to an element \( x' = (x_1, \ldots, x_n) \) of degree \( d \) such that either some of the entries \( x_i \) are negative or greater than \( d \). When translated to the root basis, this means that the coefficient of some simple root \( \alpha_i \) is negative.

**Example 4.5.** For \( (k, n) = (4, 10) \) set \( x = (3, 3, 3, 1, 1, 1, 1, 1, 1, 1)^\top \), so that in the root basis

\[
x = \begin{pmatrix} 1 & 2 & 3 & 6 & 5 & 4 & 3 & 2 & 1 & 4 \end{pmatrix}.
\]

Then \( \text{dec}(s_\beta(x)) = (1, 1, 1, 1, 1, 1, 1, 1, -1)^\top \), which in the roots basis equals

\[
\text{dec}(s_\beta(x)) = \begin{pmatrix} 1 & 2 & 3 & 4 & 3 & 2 & 1 & 0 & -1 & 2 \end{pmatrix}.
\]

Similarly, for \( (k, n) = (6, 10) \) and \( x = (3, 3, 3, 3, 3, 3, 1, 1, 1, 1)^\top \) in terms of the root basis one has

\[
x = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 3 & 2 & 1 & 4 \end{pmatrix}.
\]
while \( \text{dec}(s_\beta(x)) = (3,1,1,1,1,1,1,1,1)^T \), which translates into

\[
\text{dec}(s_\beta(x)) = \begin{pmatrix} -1 & 0 & 1 & 2 & 3 & 4 & 3 & 2 & 1 \\ 2 \end{pmatrix}.
\]

To find real roots, we consider the orbits under \( W(A_{n-1}) \) (Remark 4.1). The numbers of \( W(A_{n-1}) \)-orbits of real roots and almost real roots are listed in Table 6, and the total numbers of real roots and almost real roots are listed in Tables 7 and 8 respectively.

5. Comparison with Manin’s hyperbolic construction

In [Manin] Manin gave a construction of the root system \( E_8 \) inside a hyperbolic lattice. His construction works as follows.

Consider a 9-dimensional space \( V \) equipped with the inner product of signature \((1,8)\). This means that there exists an orthogonal basis \( f_0, f_1, \ldots, f_8 \) of \( V \) such that \((f_0, f_0) = 1, (f_i, f_i) = -1 \) for \( i \geq 1 \). Set \( \omega = -3f_0 + f_1 + \ldots + f_8 \) and define the lattice \( L = \mathbb{Z}f_0 + \ldots + \mathbb{Z}f_8 \). Then the set

\[ R = \{ f \in L \mid (f, \omega) = 0, (f, f) = -2 \} \]

is the root system of type \( E_8 \) [Manin, Proposition 25.2 and Theorem 25.4].

This realization is related to the structure of del Pezzo surfaces. If a del Pezzo surface \( V \) of degree \( d \) is not isomorphic to \( \mathbb{P}^1 \times \mathbb{P}^1 \), then its Picard group \( \text{Pic}(V) \) is isomorphic to the odd unimodular lattice \( L = I_{1,9-d} \), in which the root system is realised.

The complete enumeration of roots of \( E_8 \) is provided by [Manin, Proposition 25.5.3]. It states that if \((a, b_1, \ldots, b_8)\) are the coordinates of a root with respect to the basis \( f_0, f_1, \ldots, f_8 \), then these coordinates can be obtained from the rows of the following table by a permutation of the last 8 entries \( b_1, \ldots, b_8 \) and, possibly, a simultaneous change of the sign for all 9 entries:

| a | b_1 | b_2 | b_3 | b_4 | b_5 | b_6 | b_7 | b_8 |
|---|---|---|---|---|---|---|---|---|
| 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | -1 |
| 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| 2 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 |
| 3 | 2 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

Comparing this with the content of Table 1 reveals that this construction coincides with our presentation of \( E_8 \)-roots inside \( J_{4,9} \). The correspondence, from presentation in the \( x_i \) to presentation in the \( f_i \), is as follows

\[ x = (x_1, \ldots, x_8) \leadsto (\deg(x), x_1, \ldots, x_8), \]

(extend the presentations from Table 1 by 0s at the end where needed). For degree 0, see Remark 2.5. This is exactly the inclusion \( J_{3,8} \hookrightarrow J_{4,9} \) described in Remark 3.2.
Moreover, the exceptional curves on $V$ are parametrised by the following elements of $\text{Pic}(V)$ (with respect to $f_0, f_1, \ldots, f_n$):

| $a$ | $b_1$ | $b_2$ | $b_3$ | $b_4$ | $b_5$ | $b_6$ | $b_7$ | $b_8$ |
|-----|-------|-------|-------|-------|-------|-------|-------|-------|
| 0   | -1    | 0     | 0     | 0     | 0     | 0     | 0     | 0     |
| 1   | 1     | 1     | 0     | 0     | 0     | 0     | 0     | 0     |
| 2   | 1     | 1     | 1     | 1     | 0     | 0     | 0     | 0     |
| 3   | 2     | 1     | 1     | 1     | 1     | 1     | 1     | 0     |
| 4   | 2     | 2     | 2     | 1     | 1     | 1     | 1     | 1     |
| 5   | 2     | 2     | 2     | 2     | 2     | 2     | 1     | 1     |
| 6   | 3     | 2     | 2     | 2     | 2     | 2     | 2     | 2     |

Together with all obtained by permuting $b_1, \ldots, b_8$. The calculation of these elements in [Manin, Proposition 26.1] is done by introducing an auxiliary parameter $b_9$ and then specifying it to 1. Note, however, that for such values of $b_i$ the vector $(a, b_1, \ldots, b_8, 1)$ coincides with one of the roots of $J_{4,10}$ coming from the affine subsystem $J_{3,9}$, given by formulas (A0)–(A3) with $m = 1$. Namely, the image $\delta$ of $\delta_{3,9}$ in $J_{4,10}$ is $(3, 1, 1, 1, 1, 1, 1, 1, 1, 1)^\top$, so

(A3−): $-3 \begin{array}{c} 2 \end{array} 1 \ldots 1 + \delta = (0, -1, 0, 0, 0, 0, 0, 0, 0, 1)^\top$,

(A2−): $-2 \begin{array}{c} 1 \end{array} 1 \ldots 1 + \delta = (1, 0, 0, 0, 0, 0, 0, 1, 1, 1)^\top$,

(A1−): $-1 \begin{array}{c} 3 \end{array} 1 \ldots 1 + \delta = (2, 0, 0, 0, 1, 1, 1, 1, 1, 1)^\top$,

(A0): $e_2 - e_8 + \delta = (3, 2, 1, 1, 1, 1, 1, 1, 0, 1)^\top$,

(A1+): $\begin{array}{c} 4 \end{array} 1 \ldots 1 + \delta = (4, 2, 2, 2, 1, 1, 1, 1, 1, 1)^\top$,

(A2+): $\begin{array}{c} 6 \end{array} 1 \ldots 1 + \delta = (5, 2, 2, 2, 2, 2, 1, 1, 1, 1)^\top$,

(A3+): $3 \begin{array}{c} 7 \end{array} 2 \begin{array}{c} 1 \end{array} \ldots 1 + \delta = (6, 3, 2, 2, 2, 2, 2, 2, 2, 1)^\top$.

6. Connection with cluster algebras

Jensen, King and Su [JKS] have given an additive categorification of the cluster algebra structure on the coordinate ring $\mathbb{C}[\text{Gr}_{k,n}]$ of the Grassmannian of $k$-subspaces in $n$-space, by considering the category $\text{CM}(B_{k,n})$ of Cohen-Macaulay modules over a quotient $B_{k,n}$ of the preprojective algebra of type $\tilde{A}$.

Jensen, King and Su pointed out in [JKS, Section 8] that in the finite type cases, indecomposable modules correspond to real roots in the associated root system and that the number of indecomposable rank $d$ modules is $d$ times the number of real roots of degree $d$. They observe that this evidence suggests that rigid indecomposable modules correspond to roots (as classes in the Grothendieck group) and that for every real root of degree $d$ there are $d$ rigid indecomposable objects of rank $d$. They showed that the Grothendieck group of $\text{CM}(B_{k,n})$ can be identified with the root lattice $\Lambda(J_{k,n})$ and with the sublattice $\mathbb{Z}^n(k) \subset \mathbb{Z}^n$ spanned by the $GL_n(\mathbb{C})$ weights of the
homogeneous functions in \( \mathbb{C}[\text{Gr}(k,n)] \). Thus their "root conjecture" means that the weights of cluster variables are roots of \( J_{k,n} \).

Every \( B_{k,n} \)-module of rank 1 can be characterized by a \( k \)-element subset of \( \{1, \ldots, n\} \), see [JKS, Definition 5.1 and Proposition 5.2]. These in turn correspond to real roots in degree 1.

The rank 1 modules can be viewed as building blocks for the category as every module in \( \text{CM}(B_{k,n}) \) has a filtration with factors which are rank 1 modules, as pointed out in a private communication by A. King and M. Pressland. If \( M \) is an arbitrary module in \( \text{CM}(B_{k,n}) \), one can consider homomorphisms \( L_{I_1} \rightarrow M \) such that the quotient \( M/L_I \) is also in \( \text{CM}(B_{k,n}) \). Such homomorphisms always exist and allow to reduce the rank of \( M \). Such a filtration is not unique in general. Let \( M \) be a rank \( n \) module in \( \text{CM}(B_{k,n}) \) with factors \( L_{I_1}, \ldots, L_{I_d} \) in its filtration, where \( L_{I_d} \) is a submodule of \( M \). We write

\[
P_M = I_1 | \cdots | I_d
\]

and \( P_M \) is called the profile of \( M \). The number \( d \) is called the rank of the module \( M \).

For every module \( M \) with a profile \( P_M \) of \( d \) rows, one associates the element \( \varphi(M) = \varphi(P_M) := (x_1, \ldots, x_n)^\top \) in \( \mathbb{Z}\Delta \) where \( x_i \) is the number of occurrences of \( i \) in the profile of \( M \).

Indeed, since each of these \( d \) rows has size \( k \), the total number of entries is \( x_1 + \cdots + x_n = kd \). We have \( 0 \leq x_i \leq d \) for each \( i \in \{1, \ldots, n\} \).

Conversely, for any element \( x = (x_1, \ldots, x_n)^\top \in \mathbb{Z}\Delta \) with \( 0 \leq x_i \leq d \) for all \( i \), one can construct a profile mapping to \( x \). To do this, take the sequence

\[
a = (1, \ldots, 1, 2, \ldots, 2, \ldots, n, \ldots, n)
\]

of length \( kd \) and set

\[
I_i = \{a_{k-i+1}, a_{k-i+1+d}, \ldots, a_{k-i+1+(k-1)d}\}.
\]

Then define \( P_x := I_1 | \cdots | I_d \). This is a profile with \( \varphi(P_x) = x \). For example, for the root \( x = (2, 1, 1, 1, 1, 1, 1, 1) \) in \( J_{3,8} \), this produces

\[
\begin{align*}
P_x &= 147. \\
136
\end{align*}
\]

Now given a profile \( P \) with \( d \) rows, we order the entries increasingly in each row and write this as \( P = (P_{ij}), 1 \leq i \leq d, 1 \leq j \leq k \). So \( (P_{ij})_j \) is the \( i \)th row of the profile and \( P_{ij} < P_{i^\prime j} \) for \( j < j^\prime \). The profile \( P \) is called weakly column decreasing if for every \( j \in [k] \) and for every \( i \in [d-1] \), we have \( P_{i,j} \geq P_{i+1,j} \). If \( P \) is weakly column decreasing and in addition, we have \( P_{d,j} \geq P_{1,j-1} \) for all \( j \in [2,k] \), we say that \( P \) is canonical.
The profile $P_x$ corresponding to $x \in \mathbb{Z}\Delta$ constructed above is a canonical profile. In [BBGL, Theorem 5.7], it is shown that the profile of any rigid indecomposable module of rank 3 such that $\varphi(M)$ is a real root is a cyclic permutation of a canonical profile. For example, the profile

$$
\begin{align*}
P &= \begin{pmatrix} 258 \\ 147 \\ 136 \end{pmatrix}
\end{align*}
$$

is a canonical profile of rank 3 and $\varphi(P)$ is a real root in $J_{3,8}$. The cyclic permutations of $P$ are

$$
\begin{align*}
258 & \quad 147 & \quad 136 \\
147 & \quad 136 & \quad 258 \\
136 & \quad 258 & \quad 147
\end{align*}
$$

The modules with these profiles are all rigid indecomposable. We note that it is conjectured that whenever $M$ in $CM(B_{k,n})$ is rigid indecomposable and $\varphi(M)$ is a real root in $J_{k,n}$, then the profile $P_M$ is a cyclic permutation of a canonical profile, [BBGL, Conjecture 5.8].

The results about real roots in $J_{k,n}$ in this paper are thus expected to help with the characterization of rigid indecomposable modules in $CM(B_{k,n})$ corresponding to real roots.
