Abstract
We present a general approach to the bifurcation analysis of spatial framework structures with symmetry. While group-theoretic methods for bifurcation problems with symmetry are well known, their actual implementation in the context of geometrically exact frameworks is not straightforward. We consider spatial structures comprising assemblages of Cosserat rods; the main difficulty arises from the nonlinear configuration space, due to the presence of (cross-sectional) rotation fields. We avoid this via a single-rod formulation, developed earlier by one of the authors, whereby the governing equations are embedded in a slightly enlarged linear space. The field equations for a framework then comprise the assembly of all such rod equations, supplemented by compatibility and equilibrium conditions at the joints. We demonstrate their equivariance under the natural symmetry group action, and the implementation of group-theoretic methods is now clear within the enlarged linear space. All potential generic, symmetry-breaking bifurcations are predicted a-priori. We then employ an open-source path-following code, which can detect and compute simple, one-dimensional bifurcations; multiple bifurcation points are beyond its capabilities. For the latter, we construct symmetry-reduced problems implemented by appropriate substructures. Multiple bifurcations are rendered simple, and the path-following code

is again applicable. We first analyze a simple tripod framework, providing all details of our methodology. We then treat a more complex hexagonal space frame via the same approach. Both structures exhibit simple and double bifurcation points.

1 Introduction

Group-theoretic methods in bifurcation problems with symmetry are well established. Sattinger was the first to introduce such ideas in the context of local bifurcation analysis (Sattinger 1979). A more systematic and generic classification approach was subsequently developed by Golubitsky and co-workers (Golubitsky et al. 1988). Other monographs on the subject have also appeared, e.g., (Chossat and Lauterbach 2000; Ikeda and Murota 2010; Vanderbauwhede 1980). The use of group-theoretic ideas in global–numerical path following was first introduced in Healey 1988a, with several other works of this type following subsequently, e.g., (Dellnitz and Werner 1989; Ikeda and Murota 1991). The analyses of either simplified space truss structures or “n-box” reaction–diffusion problems are presented in these papers. The review article (Zin-goni 2009) discusses such approaches, among other things, for problems of structural mechanics. We mention that far less trivial examples of group-theoretic methods in bifurcation problems from solid/structural mechanics are presented in Combescure et al. (2016); Combescure et al. (2020); Elliott et al. (2011); Wohlever and Healey (1995). In any case, each of the above studies entails a nonlinear problem in a linear space.

We treat another class of nontrivial problems from nonlinear structural mechanics in this work, viz. spatial frameworks comprising assemblages of special Cosserat rods. The main difficulty here is that the description of even a single Cosserat rod requires a nonlinear configuration space: The orientation of each cross section is described by a finite rotation. Of course, finite rotations are not additive, and the set of all such rotations, denoted by $SO(3)$, is not a linear space. Thus, we are confronted with a nonlinear problem in a nonlinear space.

A general finite-element approach to the statics of an elastic Cosserat rod, fully embracing the nonlinear configuration space, is presented in Simo and Vu-Cuoc (1986); Newton’s method is carried out on the discretization of the nonlinear solution manifold. A simple alternative approach is provided in Healey and Mehta (2005): Quaternions are directly employed in lieu of rotations, while the mixed formulation incorporates a “dummy” parameter such that the unit quaternion equation need only be enforced at the boundary points. In this way, the problem is embedded in a slightly enlarged linear space. The number of boundary conditions (seven at each end) matches the correct number of unknowns (fourteen) in well-formulated rod problems. Any standard 2-point boundary value solver can be employed as a consequence.
The formulation introduced in Healey and Mehta (2005) is convenient for the analysis of geometrically exact Cosserat rod frameworks in 3D. This has already been observed and implemented in Yu et al. (2021). Moreover, it functions well with the open-source continuation code AUTO (Doedel et al. 2007), also employed in Yu et al. (2021) but without symmetry considerations. The code is written for nonlinear systems of first-order ordinary differential equations, which are solved accurately via the collocation method; it can detect and compute simple, single-mode bifurcations. On the other hand, multiple bifurcations points are beyond its capabilities; group-theoretic reduction becomes important. In this work, we demonstrate and exploit the equivariance of the governing equilibrium equations via group-theoretic methods. The main idea is to systematically obtain reduced problems rendering multiple bifurcations simple. A point of departure here is that we construct such reduced problems via well-chosen substructures. This is in the spirit of Bossavit (1986), but for nonlinear bifurcation problems.

The outline of the work is as follows. In Sect. 1, we first recall the equilibrium field equations for hyperelastic Cosserat rods, including their derivation via stationary potential energy. The latter is non-trivial, due to the presence of rotations; although ostensibly well known, we derive it here for completeness. More importantly, we use it to deduce group equivariance later in the work. We finish this section with a summary of the formulation presented in Healey and Mehta (2005).

In Sect. 2, we consider a simple three-rod tripod, arranged symmetrically with a rigid or “welded” joint at the crest, where a dead load along the axis of symmetry is applied. We analyze this simple model in order to set the stage for the more realistic and complicated structure treated in Sect. 3. We explicitly demonstrate the invariance of the total potential energy leading to the equivariance of the field equations and illustrate the use of group-theoretic ideas in a simple setting. We first make qualitative-generic predictions concerning potential bifurcations, cf. (Golubitsky et al. 1988; Ikeda and Murota 2010). Next, we analyze the complete structure via AUTO, revealing several simple bifurcations. We then construct a reduced problem to capture a double bifurcation. The latter is facilitated via an appropriate substructure. All bifurcations found are in consonance with the qualitative predictions—with one exception: A simple, symmetry-preserving bifurcation is also uncovered. While this does not follow from generic predictions, it is a consequence of the simultaneous flexural buckling of the rods. This also occurs in symmetric, pin-jointed tripods comprising elastic rods (Britvec 1973).

In Sect. 3, we take up the analysis of a hexagonal framework dome. This has the appearance of the simple, low-dimensional space-truss dome considered in Healey 1988a, where only 2-force members are considered. In contrast, the structural members here are deformable Cosserat rods connected by rigid joints. A centerline placement field and a cross-sectional rotation field are required to specify the configuration of each rod in the structure. The representation of symmetry and equivariance is far more complicated here, but we rely on the same approach employed in the analysis of the tripod in Sect. 2. Several group-theoretic predictions for potential bifurcations are again provided. In particular, two types of double bifurcation points are now possible. An analysis of the full structure via AUTO reveals several simple bifurcations in accordance with the qualitative predictions. We then construct two distinct reduced
problems, each implemented via a specific substructure, that capture all of the possible double bifurcations.

We also point out that a similar hexagonal Cosserat framework dome was analyzed as part of a 2004 PhD dissertation (Mohand 2004). The approach there differs from ours in several ways. The finite-element formulation of Simo and Vu-Cuoc (1986) is employed in Mohand (2004), yielding a problem in a high-dimensional nonlinear space. The equivariance of the global field equations is not discussed (but is tacitly assumed). In addition, the work employs global numerical projections onto fix-point spaces preserving subgroup symmetries, as carried out in the low-dimensional problem treated in Healey 1988a. Of course, projections are only valid in linear vector spaces. As such, they are imposed incrementally in Mohand (2004), resulting in an expensive and rather cumbersome procedure. This part of the work from the dissertation was never published.

2 Preliminaries

Notation: As is common practice, we let $\mathbb{R}^3$ denote both Euclidean 3-space and its Euclidean inner-product translate space. Vectors in $\mathbb{R}^3$ are denoted by bold-face, lower case symbols, e.g., $\mathbf{x}, \mathbf{v}$, and bold-face, upper case symbols, e.g., $\mathbf{A}, \mathbf{L}$, denote linear transformations of $\mathbb{R}^3$ into itself. The inner product between vectors $\mathbf{a}, \mathbf{b}$ is denoted $\mathbf{a} \cdot \mathbf{b}$; their right-handed cross product is written $\mathbf{a} \times \mathbf{b}$.

The transpose and determinant of $\mathbf{A}$ are denoted $\mathbf{A}^T$ and $\det \mathbf{A}$, respectively. The set of all proper rotations is given by $SO(3) = \{ \mathbf{Q} : \mathbf{Q}^{-1} = \mathbf{Q}^T, \det \mathbf{Q} = 1 \}$. For any skew-symmetric transformation $\Omega$, i.e., $\Omega^T = -\Omega$, there is a unique vector, written $\omega = axial(\Omega)$, such that $\Omega \mathbf{a} = \omega \times \mathbf{a}$ for all vectors $\mathbf{a} \in \mathbb{R}^3$.

We now summarize the formulation for a single rod pertinent to our analysis of frameworks. Let $\{ \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3 \}$ denote a fixed, right-handed orthonormal basis. We consider a straight, uniform rod occupying the reference configuration $\{ x \mathbf{e}_1 : x \in [0, L] \}$. Let $\mathbf{r}(x)$ denote the position vector (with respect to some fixed origin) of the material point that occupies $x \mathbf{e}_1$ in the reference configuration, while $\mathbf{R}(x) \in SO(3)$ denotes the rotation of the cross section of the undeformed rod contained in span$\{ \mathbf{e}_2, \mathbf{e}_3 \}$ at position $x \mathbf{e}_1$. The field $(\mathbf{r}, \mathbf{R})$ on $[0, L]$ uniquely specifies the configuration of the rod in the deformed configuration.

The last two vectors of the orthonormal field

$$\mathbf{d}_i(x) := \mathbf{R}(x) \mathbf{e}_i, \quad i = 1, 2, 3,$$

are called directors in the special Cosserat. Differentiation of (1.1) yields

$$\dot{\mathbf{d}}_i = \dot{\mathbf{R}} \mathbf{R}^T \mathbf{d}_i, \quad i = 1, 2, 3,$$

where $\mathbf{K} := \dot{\mathbf{R}} \mathbf{R}^T$ is a skew-symmetric field and $(\cdot) := d(\cdot)/dx$. Hence, there is a unique axial vector field

$$\kappa = axial(\mathbf{K})$$
such that (1.2) is equivalent to
\[ \dot{d}_i = \kappa \times d_i, \quad i = 1, 2, 3. \]
We then write
\[ \dot{r} = v_i d_i \text{ and } \kappa = \kappa_i d_i. \] (1.4)

The six components \( v_i, \kappa_i, i = 1, 2, 3 \), comprise the strain measures of the theory. We assume that the rod is hyperelastic, viz. there is smooth stored energy function
\[ W(v_1, v_2, v_3, \kappa_1, \kappa_2, \kappa_3), \quad W : (0, \infty) \times \mathbb{R}^5 \to \mathbb{R}, \]
such that
\[ n = \frac{\partial W}{\partial v_i} d_i \text{ and } m = \frac{\partial W}{\partial \kappa_i} d_i \] (1.5)
correspond to the contact force and contact couple fields, respectively. Moreover, the total internal potential energy of the rod is given by
\[ U[r, R] := \int_0^L W(v_1, v_2, v_3, \kappa_1, \kappa_2, \kappa_3) \, dx = \int_0^L W(R^T \dot{r}, R^T \kappa) \, dx, \] (1.6)
where we have made use of (1.1) and (1.4) in obtaining the right side of (1.6). For simplicity, we assume the absence of external body force and body couple fields. The following is well known but not well documented in the literature:

**Proposition 1.1** The first-variation condition (stationary potential energy) for (1.6) formally delivers the balance-of-forces and balance-of-moments equilibrium equations.
\[ \dot{n} = 0 \text{ and } \dot{m} + \dot{r} \times n = 0 \text{ in } (0, L), \] (1.7)
respectively, with \( n \) and \( m \) given by (1.5).

**Proof.** See Appendix 1.

Next, we suppose that the uniform rod has cross-sectional reflection symmetry across the plane spanned by \( \{e_1, e_3\} \). Let \( E \) denote the reflection transformation defined by
\[ E e_1 = e_1, \quad E e_2 = -e_2, \quad E e_3 = e_3. \] (1.8)

From the formulation in Healey (2002), a hyperelastic rod with such symmetry satisfies the invariance condition
\[ W(ER^T v, -ER^T \kappa) \equiv W(R^T v, R^T \kappa). \] (1.9)

The negative sign in (1.9) follows from the fact that \(-E \omega\) is the axial vector of \( E \Omega E \) for any skew-symmetric transformation \( \Omega \) with axial vector \( \omega \).

Finally, we summarize the formulation presented in Healey and Mehta (2005), which we employ in our forthcoming analyses. First, we express (1.7) in componential
form relative to the director basis field \( \{d_1, d_2, d_3\} \). We write such components as triples of the form \( n = (n_1, n_2, n_3), \nu = (\nu_1, \nu_2, \nu_3) \), etc. Then, (1.7) is equivalent to

\[
\dot{n} = n \times \kappa, \\
\dot{m} = m \times \kappa + n \times \nu.
\]  

(1.10)

We assume that the \( 6 \times 6 \) Hessian matrix \( D^2 W(\cdot) \) is positive definite for each of its arguments on \((0, \infty) \times \mathbb{R}^5\), which insures the existence of a complementary energy density \( \Gamma(n, m) \) (the Legendre transform of \( W \)) such that

\[
\nu = \frac{\partial \Gamma}{\partial n} \quad \text{and} \quad \kappa = \frac{\partial \Gamma}{\partial m}.
\]  

(1.11)

The substitution of (1.11) into (1.10) gives

\[
\dot{n} = n \times \frac{\partial \Gamma}{\partial m}, \\
\dot{m} = m \times \frac{\partial \Gamma}{\partial m} + n \times \frac{\partial \Gamma}{\partial n}.
\]  

(1.12)

Next, we express the placement fields \( r, R \) in terms of their components with respect to the fixed basis, viz.

\[
r = r_i e_i, \quad \mathbf{r} := (r_1, r_2, r_3), \\
R = R_{ij} e_i \otimes e_j, \quad \mathbf{R} := [R_{ij}],
\]  

(1.13)

where \([R_{ij}]\) represents the \( 3 \times 3 \) matrix of components. We henceforth express all components with respect to the fixed basis with an overbar, as above in (1.13). According to Euler’s theorem, there is an “instantaneous” axis of rotation corresponding to a real eigenvector \( n \) with \( Rn = n \). Let \( \phi \in \mathbb{R}(\text{mod}2\pi) \) denote the counterclockwise angle of rotation about \( n \) (according to the right-hand rule), given by the trace formula

\[
tr R = 1 + 2 \cos \phi.
\]

Choosing \( n \cdot n = 1 \), we associate \( R \) with the quaternion

\[
q = (q_o, \mathbf{q}), \\
q_o := \cos(\phi/2), \mathbf{q} := \sin(\phi/2)n.
\]  

(1.14)

Writing \( \mathbf{q} = q_i e_i \), it follows that

\[
q_o^2 + \mathbf{q} \cdot \mathbf{q} = q_o^2 + q_1^2 + q_2^2 + q_3^2 = 1,
\]  

(1.15)

and the matrix \( \mathbf{R} \) admits the parametrization

\[
\mathbf{R}(\mathbf{q}) = 2 \begin{bmatrix} q_o^2 + q_1^2 - 1/2 & q_1 q_2 - q_o q_3 & q_1 q_3 + q_o q_2 \\
q_1 q_2 + q_o q_3 & q_o^2 + q_2^2 - 1/2 & q_2 q_3 - q_o q_1 \\
q_1 q_3 - q_o q_2 & q_2 q_3 + q_o q_1 & q_o^2 + q_3^2 - 1/2 \end{bmatrix}
\]  

(1.16)
where \( \bar{q} := (q_o, q_1, q_2, q_3) \). Finally, as derived in Healey and Mehta (2005), we have

\[
\dot{r} = \bar{R}(\bar{q}) \nu = \bar{R}(\bar{q}) \frac{\partial \Gamma}{\partial n},
\]

\[
\dot{q} = A(\bar{q}) \kappa + \mu \bar{q} = A(\bar{q}) \frac{\partial \Gamma}{\partial n} + \mu \bar{q},
\]

where \( \mu \in \mathbb{R} \) is an unspecified (dummy) parameter and

\[
A(\bar{q}) := \begin{bmatrix}
-q_1 & -q_2 & -q_3 \\
q_o & -q_3 & q_2 \\
q_3 & q_o & -q_1 \\
-q_2 & q_1 & q_o
\end{bmatrix}
\]

(1.17)

The field equations comprise (1.12) and (1.17). As shown in Healey and Mehta (2005), if (1.15) is satisfied at the endpoints, then \( \mu \) is zero and (1.15) automatically holds over \((0, L)\), i.e., (1.15) is not a required field equation. For a rotational boundary condition of place, (1.15) is automatically satisfied at that boundary point. On the other hand, if an applied couple is imposed or if a “mixed” rotational boundary condition is prescribed, then (1.15) must be specified at that boundary point as well. Either way, seven boundary conditions are always prescribed at each end, which agrees with the fourteen unknowns \( n, m, r, q \) and \( \mu \). In practice via finite precision arithmetic, \( \mu \) computes to an extremely small value.

3 A Simple Tripod Framework with Symmetry

3.1 Formulation and Equivariance

We first consider a simple tripod composed of three identical, straight, prismatic, unstressed, hyperelastic rods of length \( L \) all meeting at a perfectly rigid or welded joint at \( A \), i.e., all rods have the same displacement and rotation at the joint. The rods are arranged symmetrically, the supports of the rods are identical, and we assume that the angle between the horizontal plane and each bar is \( \pi/3 \) radians, cf. Figure 1. Let \( \{i_1, i_2, i_3\} \) denote a fixed orthonormal global basis for \( \mathbb{R}^3 \) and let \( \{e_1^{(j)}, e_2^{(j)}, e_3^{(j)}\} \) be the fixed orthonormal local basis oriented along the \( j^{th} \) undeformed rod, \( j = 1, 2, 3 \), such that

\[
e_1^{(1)} = (1/2)i_1 - (\sqrt{3}/2)i_3, \quad e_2^{(1)} = i_2, \quad e_3^{(1)} = (\sqrt{3}/2)i_1 + (1/2)i_3, \\
e_j^{(2)} = R_{2\pi/3} e_j^{(1)}, \quad e_j^{(3)} = R_{2\pi/3} e_j^{(2)} = R_{4\pi/3} e_j^{(1)}, \quad j = 1, 2, 3,
\]

(2.1)
where $R_{2\pi/3}$ denotes a clockwise rotation through the angle $2\pi/3$ about $i_3$; its matrix relative to the fixed global basis is given by

$$
[R_{2\pi/3}] = \frac{1}{2} \begin{bmatrix}
-1 & \sqrt{3} & 0 \\
-\sqrt{3} & -1 & 0 \\
0 & 0 & 2
\end{bmatrix}.
$$

In what follows, repeated subscripts sum (Einstein convention) while repeated parenthetical superscripts, labeling the rods, do not. We assume that the $j^{th}$ rod has reflection symmetry across the plane spanned by $\{e_1^{(j)}, e_3^{(j)}\}$.

A configuration of the tripod is uniquely described by the placement and orientation field of each rod, represented by

$$
u := (r_1^{(1)}, R_1^{(1)}, r_2^{(2)}, R_2^{(2)}, r_3^{(3)}, R_3^{(3)}),
$$

where $r_1^{(j)} : [0, L] \rightarrow \mathbb{R}^3$ and $R_1^{(j)} : [0, L] \rightarrow SO(3)$ denote the placement and rotation field of the deformed $j^{th}$ rod, respectively, $j = 1, 2, 3$; each is presumed to be continuously differentiable.

For compatibility at joint A, we require

$$
r_1^{(1)}(0) = r_2^{(2)}(0) = r_3^{(3)}(0) := r_A,
$$

$$
R_1^{(1)}(0) = R_2^{(2)}(0) = R_3^{(3)}(0) := R_A.
$$

where $r_A, R_A$, the joint placement and orientation, respectively, are unknowns.
If the supported ends of the rods are clamped, we require
\[ r^{(1)}(L) = (L/2)i_1, \quad r^{(2)}(L) = (L/2)R_{2\pi/3}i_1, \quad r^{(3)}(L) = (L/2)R_4i_1, \]
\[ R^{(1)}(L) = R^{(2)}(L) = R^{(3)}(L) = I, \]
where I denotes the identity. For “ball-in-socket” supports, (2.5) still hold along with the vanishing of all end moments, viz.
\[ m^{(j)}(0) = 0, \quad j = 1, 2, 3, \]
where \( m^{(j)} : (0, L) \to \mathbb{R}^3 \) denotes the contact-couple field for the \( j^{th} \) rod, \( j = 1, 2, 3 \).
In this case, an additional boundary condition, corresponding to (1.15) evaluated at \( x = L \), must also be incorporated. Of course, other compatibility/boundary conditions are possible, e.g., fixed supports (2.5) with a ball-in-socket at joint A, implying vanishing torques as in (2.6) but evaluated at \( x = 0 \). Other “mixed” conditions (symmetrically arranged) are possible, the explicit details of which we do not present.

We assume that the tripod is subjected to a dead, concentrated load at joint A of the form \( -\lambda i_3 \). The total potential energy of the structure is then given by
\[ V[\lambda, \mathbf{u}] = \mathcal{U}[\mathbf{u}] + \lambda \mathbf{r}_A \cdot \mathbf{i}_3, \]
where
\[ \mathcal{U}[\mathbf{u}] := \sum_{j=1}^{3} \int_{0}^{L} W([R^{(j)}]T \mathbf{r}^{(j)}, [R^{(j)}]T \kappa^{(j)})dx, \]
and \( W : (0, \infty) \times \mathbb{R}^5 \to \mathbb{R} \) is the stored-energy function, common to each of the rods.

**Proposition 2.1** The first-variation condition (stationary potential energy) for (2.7) delivers the balance-of-forces and balance-of-moments equilibrium equations and the joint equilibrium conditions:
\[ \dot{n}^{(j)} = 0 \quad \text{and} \quad \dot{m}^{(j)} + \dot{r}^{(j)} \times \mathbf{n}^{(j)} = 0 \quad \text{in} \quad (0, L), \quad j = 1, 2, 3, \]
\[ \sum_{j=1}^{3} n^{(j)}(0) - \lambda i_3 = 0, \quad \sum_{j=1}^{3} m^{(j)}(0) = 0, \]
respectively, where \( n^{(j)} = \frac{\partial W}{\partial \dot{v}_i^{(j)}} d_i^{(j)} \) and \( m^{(j)} = \frac{\partial W}{\partial \dot{\kappa}_i^{(j)}} d_i^{(j)} \), \( j = 1, 2, 3 \).

**Proof.** See Appendix 1.

In order to employ formulation (1.12), (1.17), we first replace (2.8)3 with
\[ v^{(j)} = \frac{\partial \Gamma}{\partial n^{(j)}} \quad \text{and} \quad \kappa^{(j)} = \frac{\partial \Gamma}{\partial m^{(j)}}, \quad j = 1, 2, 3. \]
We also have the system (1.12)-(1.18) for each of the rods, denoted by a parenthetical superscript \( j = 1, 2, 3 \). We do not rewrite these here. Finally, we replace (2.3), (2.4)\(^2\) and (2.5)\(^2\) by

\[
\begin{align*}
\mathbf{u} & := \left( r^{(1)}, q^{(1)}, r^{(2)}, q^{(2)}, r^{(3)}, q^{(3)} \right), \\
q^{(1)}(0) &= q^{(2)}(0) = q^{(3)}(0), \\
q^{(1)}(L) &= q^{(2)}(L) = q^{(3)}(L) = (1, 0),
\end{align*}
\]

respectively. We remark that a given a unit quaternion \( q = (q_0, \mathbf{q}) \), \( (q_0)^2 + \mathbf{q} \cdot \mathbf{q} = 1 \), corresponds to a unique rotation. However, there are two choices for a unit quaternion for a given rotation \( \mathbf{R} \in SO(3) \): If \( q \) corresponds to \( \mathbf{R} \), then so too does \(-q\). Nonetheless, this causes us no problems: Once a choice has been made, we employ only continuous unit quaternion fields as functions of continuation parameters.

The tripod possesses the symmetry group \( C_{3v} \), generated by the rotation \( \mathbf{R}_{2\pi/3} \) and the reflection across the plane spanned by \( \{i_1, i_3\} \). We denote the latter transformation by \( \mathbf{E} \), which has the matrix

\[
[E] = \begin{bmatrix}
1 & 0 & 0 \\
0 & -1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

relative to the global basis. More specifically,

\[
C_{3v} = \{ \mathbf{R}_{2k\pi/3}, \mathbf{E}\mathbf{R}_{2k\pi/3} : k = 1, 2, 3 \}.
\]

Observe that the transformation \( \mathbf{E}\mathbf{R}_{2k\pi/3} \) represents a reflection across the plane spanned by \( \{\mathbf{R}_{k\pi/3}i_1, i_3\}, k = 1, 2, 3 \), where \( \mathbf{R}_{k\pi/3} \) denotes the clockwise rotation about \( i_3 \) through the angle \( k\pi/3 \).

The natural group action of \( C_{3v} \) on configuration space (2.10)\(^1\) is generated by

\[
T_{\mathbf{R}_{2\pi/3}} \mathbf{u} := (\mathbf{R}_{2\pi/3} r^{(3)}, \mathbf{R}_{2\pi/3} q^{(3)}, \mathbf{R}_{2\pi/3} r^{(1)}, \mathbf{R}_{2\pi/3} q^{(1)}, \mathbf{R}_{2\pi/3} r^{(2)}, \mathbf{R}_{2\pi/3} q^{(2)})
\]

and

\[
T_{\mathbf{E}} \mathbf{u} := (\mathbf{E}r^{(1)}, \mathbf{E}q^{(1)}, \mathbf{E}r^{(3)}, \mathbf{E}q^{(3)}, \mathbf{E}r^{(2)}, \mathbf{E}q^{(2)}),
\]

where the actions on unit quaternions are defined as follows:

\[
R_{2\pi/3} q := (q_0, \mathbf{R}_{2\pi/3} q), \\
\mathbf{E}q := (q_0, -\mathbf{E}q).
\]

The group generated by the transformations (2.13) is a faithful representation of \( C_{3v} \) on configuration space. Observe that (2.13)\(^1\) corresponds to a rotation of a configuration (2.10)\(^1\) about \( i_3 \) through the clockwise angle \( 2\pi/3 \), while (2.13)\(^2\) represents a
reflection of a configuration across the plane spanned by \( \{i_1, i_3\} \). The other elements in the group \( \{T_{R_2 \pi/3}, T_{E} T_{R_2 \pi/3} = T_{ER_2 \pi/3}, j = 1, 2, 3\} \) have similar interpretations. For that reason, the representation is termed *natural*.

Our first task here is to establish:

**Proposition 2.2** The potential energy (2.7) is invariant under the representation generated by the transformations (2.13), i.e.,

\[
\mathcal{V}[\lambda, T_G u] = \mathcal{V}[\lambda, u] \quad \text{for all } G \in C_3v. \tag{2.15}
\]

**Proof.** It is enough to show that (2.15) holds for the generators (2.13). First notice that

\[
\begin{align*}
R_{2 \pi/3} & \rightarrow R_{2 \pi/3} R_{2 \pi/3}, \\
R_2 & \rightarrow R_2 R_{2 \pi/3}, \quad j = 1, 2, 3.
\end{align*}
\]

In view of (2.1) and (2.7) 2, we deduce from (2.16) that

\[
[R^{(j)}]T \rightarrow \nu^{(j)} e^{(j+1)}_i, \quad j = 1, 2, 3, \tag{2.17}
\]

with the understanding that

\[
e^{(4)}_i \equiv e^{(1)}_i, \quad i = 1, 2, 3. \]

Obviously this goes the same way for the last three arguments of \( W \), viz.

\[
k^{(j)} \rightarrow R_{2 \pi/3} k^{(j)} \quad \text{and} \quad R^{(j)} \rightarrow R_{2 \pi/3} R^{(j)} R_{2 \pi/3} \Rightarrow [R^{(j)}]T k^{(j)} \rightarrow k^{(j)} e^{(j+1)}_i, \quad j = 1, 2, 3. \tag{2.18}
\]

Then, (2.7), (2.13) 1, (2.17) and (2.18) imply

\[
\mathcal{V}[\lambda, T_{R_{2 \pi/3}} u] = \frac{3}{2} \sum_{j=1}^{3} \int_{0}^{L} W(\nu^{(j)}_i e^{(j+1)}_i, k^{(j)}_i e^{(j+1)}_i) dx + \lambda R_{2 \pi/3} r_A \cdot i_3.
\]

In particular, the strains from the \( j^{th} \) rod “move” to the \((j + 1)^{th}\) rod under the transformation, and the invariance of the internal potential energy is now clear. The loading term is also invariant: \( R_{2 \pi/3} i_3 = i_3 \) and \( R_{2 \pi/3} r_A \cdot R_{2 \pi/3} i_3 = r_A \cdot i_3 \). Given that the compatibility and boundary conditions (2.4), (2.5), and (2.10) are unaffected by (2.13) 1, we conclude that (2.15) holds for \( G = R_{2 \pi/3} \).

The demonstration for \( T_{E} \) requires more care, due to the reflection symmetry of each individual rod. The first step is similar to (2.16):

\[
r^{(j)} \rightarrow E r^{(j)} \quad \text{and} \quad q^{(j)} \rightarrow E q^{(j)} \Rightarrow R^{(j)} \rightarrow E R^{(j)} E, \quad j = 1, 2, 3. \tag{2.19}
\]
Hence,\[
\dot{T}\mathbf{r}^{(j)} \rightarrow E[R^{(j)}]^T \dot{r}^{(j)},
\]
\[
[R^{(j)}]^T \kappa^{(j)} = \text{axial}([R^{(j)}]^T \dot{R}^{(j)}) \rightarrow \text{axial}(E[R^{(j)}]^T \dot{R}^{(j)} E) = -E[R^{(j)}]^T \kappa^{(j)}.
\]
(2.20)

Next, we note\[
E e_1^{(1)} = e_1^{(1)}, \quad E e_2^{(1)} = -e_2^{(1)}, \quad E e_3^{(1)} = e_3^{(1)},
\]
\[
E e_1^{(2)} = e_1^{(3)}, \quad E e_2^{(2)} = -e_2^{(3)}, \quad E e_3^{(2)} = e_3^{(3)}.
\]
(2.21)

Then, (2.7), (2.13) 2, (2.19)-(2.21) yield\[
\mathcal{V}[^\lambda, T_E u] = \int_0^L [W(v_1^{(1)} e_i^{(1)}, \kappa_i^{(1)} e_i^{(1)}) - E^{(1)}[\kappa_i^{(1)} e_i^{(1)}])] dx
\]
\[+ \int_0^L [W(v_1^{(2)} e_1^{(2)} + v_2^{(2)} e_2^{(2)} + v_3^{(2)} e_3^{(2)}, \kappa_1^{(2)} e_1^{(2)} + \kappa_2^{(2)} e_2^{(2)} + \kappa_3^{(2)} e_3^{(2)})] dx
\]
\[+ \int_0^L [W(v_1^{(3)} e_1^{(3)} + v_2^{(3)} e_2^{(3)} + v_3^{(3)} e_3^{(3)}, \kappa_1^{(3)} e_1^{(3)} + \kappa_2^{(3)} e_2^{(3)} + \kappa_3^{(3)} e_3^{(3)})] dx
\]
\[+ \lambda r_A \cdot i_3,
\]
(2.22)

where \(E^{(j)}\) denotes the reflection across the plane spanned by \(\{e_1^{(j)}, e_3^{(j)}\}, j = 1, 2, 3\). Now use the fact that \(E_i 3 = i_3\) along with cross-sectional reflection symmetry (1.9) to see that (2.22) becomes\[
\mathcal{V}[^\lambda, T_E u] = \int_0^L [W(v_1^{(1)} e_i^{(1)}, \kappa_i^{(1)} e_i^{(1)})] dx
\]
\[+ \int_0^L [W(v_1^{(2)} e_1^{(2)} + v_2^{(2)} e_2^{(2)} + v_3^{(2)} e_3^{(2)}, \kappa_1^{(2)} e_1^{(2)} + \kappa_2^{(2)} e_2^{(2)} + \kappa_3^{(2)} e_3^{(2)})] dx
\]
\[+ \int_0^L [W(v_1^{(3)} e_1^{(3)} + v_2^{(3)} e_2^{(3)} + v_3^{(3)} e_3^{(3)}, \kappa_1^{(3)} e_1^{(3)} + \kappa_2^{(3)} e_2^{(3)} + \kappa_3^{(3)} e_3^{(3)})] dx
\]
\[+ \lambda r_A \cdot i_3,
\]
(2.23)

In this case, the strains from rod 3 move to rod 2 and vice versa under the transformation. It is straightforward to demonstrate that the compatibility and boundary conditions (2.4), (2.5) and (2.10) are unaffected by (2.13) 2. We conclude that (2.23) is precisely the same as \(\mathcal{V}[^\lambda, u]\) \(\Box\).

We now use the invariance of the potential energy (2.15) to establish the equivariance of the governing Eqs. (2.10), the proof of which is provided in Appendix 1.

**Proposition 2.3** The equilibrium Eqs. (2.8) are equivariant, i.e.,\[
\langle \delta \mathcal{V}[^\lambda, T_G u], h \rangle = \langle \tilde{T}_G \delta \mathcal{V}[^\lambda, u], h \rangle.
\]
(2.24)
for all \( G \in C_3^v \) and for all admissible variations \( h := (\eta^{(1)}, \theta^{(1)}, \eta^{(2)}, \theta^{(2)}, \eta^{(3)}, \theta^{(3)}) \), satisfying the end conditions (in consonance with (2.4), (2.5))

\[
\begin{align*}
\eta^{(j)}(L) &= 0, \quad \theta^{(j)}(L) = 0, \quad j = 1, 2, 3, \\
\eta^{(1)}(0) &= \eta^{(2)}(0) = \eta^{(3)}(0), \quad \theta^{(1)}(0) = \theta^{(2)}(0) = \theta^{(3)}(0).
\end{align*}
\]  

(2.25)

Here the generators of the action of \( \tilde{T}_G \) on \( \sigma := \delta V \) are defined by

\[
\begin{align*}
\tilde{T}_{R_2\pi/3}\sigma &:= (R_{2\pi/3}n^{(3)}, R_{2\pi/3}m^{(3)}, R_{2\pi/3}n^{(1)}, R_{2\pi/3}m^{(1)}, R_{2\pi/3}n^{(2)}, R_{2\pi/3}m^{(2)}), \\
\tilde{T}_{E}\sigma &:= (En^{(1)}, -Em^{(1)}, En^{(3)}, -Em^{(3)}, En^{(2)}, -Em^{(2)}),
\end{align*}
\]

(2.26)

for all \( \sigma = (n^{(1)}, m^{(1)}, n^{(2)}, m^{(2)}, n^{(3)}, m^{(3)}) \), and the inner product employed in (2.24) is defined by

\[
\langle \sigma, h \rangle := 3 \sum_{j=1}^{3} \int_{0}^{L} (n^{(j)} \cdot \eta^{(j)} + m^{(j)} \cdot \theta^{(j)}) dx.
\]

(2.27)

**Proof.** See Appendix 1.

We express (2.24) abstractly in the strong form via

\[
\begin{align*}
f(\lambda, T_G u) &= \tilde{T}_G f(\lambda, u) \quad \text{for all } G \in C_3^v, \\
f(\lambda, u) &= 0
\end{align*}
\]

(2.28)

where

\[
f(\lambda, u) = 0
\]

(2.29)

represents the strong form of the equilibrium Eqs. (2.8).

### 3.2 Exploitation of Symmetry and Bifurcation

It is well known that equivariance (2.28) implies that the nonlinear operator in (2.29) admits linear invariant subspaces, which we now outline. Let \( \mathcal{X} \) denote configuration space, defined via (2.10) 1,v i z.

\[
\mathcal{X} = (C^1([0, L], \mathbb{R}^3) \times C^1([0, L], S^3))^3.
\]

(2.30)

where \( S^3 \) is the set of all unit quaternions, and let \( \mathcal{X}_o \) denote subset of all configurations satisfying the boundary conditions and joint compatibility conditions, viz. (2.4) 1, (2.5) 1 and (2.10) 2,3. Then, \( f : \mathbb{R} \times \mathcal{X}_o \rightarrow \mathcal{Y} \), where the target space is the linear vector
space $\mathcal{Y} = C([0, L], \mathbb{R}^{18})$. Let $\Sigma \subset C_{3v}$ be a subgroup of the tripod symmetry group $C_{3v}$, and define the $\Sigma$ fixed-point space

$$
\mathcal{X}_o^\Sigma := \{ u \in \mathcal{X}_o : T_G u = u \text{ for all } G \in \Sigma \}. \tag{2.31}
$$

This is simply the set of all admissible configurations enjoying the symmetry characterized by the subgroup $\Sigma$. In any case, (2.28) implies

$$
f(\lambda, \cdot) : \mathbb{R} \times \mathcal{X}_o^\Sigma \to \mathcal{Y}_o^\Sigma, \tag{2.32}
$$

where $\mathcal{Y}_o^\Sigma$ is the target fixed-point space

$$
\mathcal{Y}_o^\Sigma := \{ y \in \mathcal{Y} : \tilde{T}_G y = y \text{ for all } G \in \Sigma \}.
$$

Indeed, if $u \in \mathcal{X}_o^\Sigma$, then (2.28) and (2.31) immediately give $f(\lambda, u) = f(\lambda, T_G u) = \tilde{T}_G f(\lambda, u)$ for all $G \in \Sigma$.

The main idea is to choose subgroups strategically, viz. in such a way that the symmetry-reduced bifurcation problem (2.29), (2.32) entails only a 1-dimensional (single-mode) bifurcation analysis, which is considerably simpler than the analysis of a multiple-bifurcation point. This is usually called the equivariant branching lemma. In particular, numerical branch switching is routine in the 1D case. We use generic, local-bifurcation arguments (Golubitsky et al. 1988; Ikeda and Murota 2010) to guide our analyses before computing solution paths. The group $C_{3v}$ has three non-equivalent irreducible representations (irreps), denoted $\gamma^{(k)}_G$, $k = 1, 2, 3$, with generators

$$
\begin{align*}
\gamma^{(1)}_{R_{2\pi/3}} &= \gamma_E^{(1)} = 1, \\
\gamma^{(2)}_{R_{2\pi/3}} &= -\gamma_E^{(2)} = 1, \\
\gamma^{(3)}_{R_{2\pi/3}} &= \frac{1}{2} \begin{bmatrix} -1 & \sqrt{3} \\ -\sqrt{3} & -1 \end{bmatrix}, \\
\gamma_E^{(3)} &= \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix},
\end{align*}
\tag{2.33}
$$

respectively, cf. (McWeeny 2002). The first irrep (1) is always associated with symmetry-preserving configurations, while the other two provide a preview of the type of potential symmetry-breaking bifurcation modes we can expect.

Irrep (2) is associated with a potential 1-dimensional bifurcation, preserving rotational symmetry while breaking reflection symmetry. The latter conclusion follows from the observation that $\gamma_E^{(2)} = -1$. The single bifurcation equation—in the parameter $\lambda$ and the unknown amplitude—is odd in the latter variable. Consequently, the bifurcation will be a “pitchfork.”

Irrep (3) is associated with a potential double bifurcation point, i.e., the null space of the tangent stiffness is generically 2-dimensional. This is in consonance with the fact that representation (3) involves $2 \times 2$ matrices. Unlike the previous case, there are now two local bifurcation equations—in the parameter $\lambda$ and two unknown amplitudes. Moreover, the bifurcation equations are equivariant under the matrix representation $\gamma^{(3)}$, the latter of which is the complete symmetry group of an equilateral triangle in the
Table 1 Geometric characteristics of bar cross sections

| Type of section | Width \(w(m)\) | Height \(h(m)\) | Moment of inertia \(I_2(m^4)\) | Moment of inertia \(I_3(m^4)\) | Torsional moment of inertia \(J(m^4)\) | Area | Shear area |
|-----------------|----------------|----------------|-----------------|-----------------|-----------------|------|-----------|
| Square          | \(\frac{6}{34}\) | \(\frac{6}{34}\) | \(\frac{w^3h}{2}\)  \(\approx\) 8.08210^{-5} | \(\frac{wh^3}{12}\) | 0.141hw^3 | \(wh\) | \(\frac{5wh}{6}\) |

plane, denoted \(D_3\). There are three equivalent ways to break the symmetry leaving that of an isosceles triangle. For instance, one of these has the symmetry group \(\Sigma = \{I, E\}\). Accordingly, we expect three equivalent bifurcating branches. It is enough to compute only one; by virtue of (2.28), (2.29), the other two can be generated via consecutive actions of (2.13)\(_i\). One such branch of solutions can be computed efficiently as a 1-dimensional bifurcation via the restriction (2.32) employing the simple reflection subgroup \(\Sigma\) just mentioned. Finally, we mention that the equivariance of the bifurcation equations under \(\gamma(3)\) also implies that the bifurcation equations exhibit a quadratic term. Thus, a potential bifurcation will be transcritical in this case.

For the purpose of numerical computations, we choose the following quadratic, “diagonal” complementary energy function for each of the rods in the tripod:

\[
\Gamma = \frac{L}{2} \left( \frac{n_1^2 + n_2^2 + n_3^2}{EA} + 2n_1 + \frac{m_1^2}{GJ} + \frac{m_2^2}{EI_2} + \frac{m_3^2}{EI_3} \right), \tag{2.34}
\]

with Young’s modulus \(E = 10^5 \text{ Pa}\), shear modulus \(G = E/2\), cross-sectional area \(A\), shear area \(A_S\), torsional moment of inertia \(J\), and bending moments of inertia \(I_1, I_2\). We choose \(L = 1\) for the rod lengths. Although this appears trivial here, we leave the multiplicative factor “\(L\)” in (2.34), anticipating structures for which the structural members need not have the same lengths, as in Sect. 3. We assume square cross sections with geometric properties summarized in Table 1.

We employ the path-following code AUTO (Doedel et al. 2007), which detects and computes simple (single-mode) bifurcations. As such, we begin with an analysis of the full tripod without symmetry restrictions in order capture the symmetry-preserving primary solution and any potential bifurcations associated with irrep \(\gamma(2)\). The field equations in local coordinates for each rod are given by (1.12) and (1.17), supplemented by (1.16) and (1.18). For each rod, we index all quantities appearing in the set of equations by a parenthetical superscript, viz. \(\bar{\tau}^{(j)}, \bar{\mathbf{q}}^{(j)} = (q^{(j)}, \bar{q}^{(j)}), \bar{\mathbf{n}}^{(j)}, \bar{\mathbf{m}}^{(j)}, j = 1, 2, 3\). Similarly, the compatibility Eqs. (2.4)\(_1\), (2.10)\(_2\), the boundary conditions (2.5)\(_1\), (2.10)\(_3\), and the equilibrium conditions (2.8)\(_2\) at joint A all need to be written with respect to the local coordinate system of each rod.

We first introduce

\[
i_k = \mathbf{Q}e_k^{(1)}, \ k = 1, 2, 3, \tag{2.35}
\]

\(\mathbf{Q}\) Springer
where $\mathbf{Q}$ is the rotation with matrix relative to the global basis given by

$$[\mathbf{Q}] = \frac{1}{2} \begin{bmatrix} 1 & 0 & \sqrt{3} \\ 0 & 1 & 0 \\ -\sqrt{3} & 0 & 1 \end{bmatrix},$$

the latter of which follows directly from (2.1)\textsubscript{1}. By virtue of (2.1)\textsubscript{2} and (2.2), the compatibility Eqs. (2.4)\textsubscript{1}, (2.10)\textsubscript{2} become

$$[\mathbf{Q}] \bar{r}^{(1)}(0) = [R_{2\pi/3}] [\mathbf{Q}] \bar{r}^{(2)}(0) = [R_{4\pi/3}] [\mathbf{Q}] \bar{r}^{(3)}(0),$$

$q_o^{(1)}(0) = q_o^{(2)}(0) = q_o^{(3)}(0), \text{ and}$

$$[\mathbf{Q}] \bar{q}^{(1)}(0) = [R_{2\pi/3}] [\mathbf{Q}] \bar{q}^{(2)}(0) = [R_{4\pi/3}] [\mathbf{Q}] \bar{q}^{(3)}(0),$$

respectively. Similarly, the boundary conditions (2.5)\textsubscript{1}, (2.10)\textsubscript{3} now read

$$[\mathbf{Q}] \bar{r}^{(1)}(1) = [\mathbf{Q}] \bar{r}^{(2)}(1) = [\mathbf{Q}] \bar{r}^{(3)}(1) = \begin{bmatrix} L/2 \\ 0 \\ 0 \end{bmatrix},$$

$q_o^{(1)}(1) = q_o^{(2)}(1) = q_o^{(3)}(1) = 1,$ \text{ and}

$$\bar{q}^{(1)}(1) = \bar{q}^{(2)}(1) = \bar{q}^{(3)}(1) = \bar{0},$$

respectively. For joint equilibrium, we first recall from Sect. 1 that $\mathbf{n}^{(j)} = n_k^{(j)} \mathbf{R}^{(j)} e_k^{(j)}, \ j = 1, 2, 3,$ where $\mathbf{R}^{(j)} = R_{kl}^{(j)} e_k^{(j)} \otimes e_l^{(j)}$. Then, by (2.1)\textsubscript{2} and (2.35), (2.8)\textsubscript{2} reads

$$[\mathbf{Q}] \bar{r}^{(1)}(0) p^{(1)}(0) + [R_{2\pi/3}] [\mathbf{Q}] \bar{r}^{(2)}(0) p^{(2)}(0) + [R_{4\pi/3}] [\mathbf{Q}] \bar{r}^{(3)}(0) p^{(3)}(0) = \begin{bmatrix} 0 \\ 0 \\ \lambda \end{bmatrix},$$

$$[\mathbf{Q}] \bar{r}^{(1)}(0) m^{(1)}(0) + [R_{2\pi/3}] [\mathbf{Q}] \bar{r}^{(2)}(0) m^{(2)}(0) + [R_{4\pi/3}] [\mathbf{Q}] \bar{r}^{(3)}(0) m^{(3)}(0) = 0.$$  

(2.39)

The formulation from Healey and Mehta (2005), outlined in Sect. 1, also requires the specification of (1.15) as a boundary condition whenever the latter does not involve a purely kinematic rotation. In view of (2.37)\textsubscript{2,3}, it is enough to prescribe

$$(q_o^{(1)}(0))^2 + \bar{q}^{(1)}(0) \cdot \bar{q}^{(1)}(0) = 1.$$  

(2.40)

We note that (2.38) represents 21 boundary conditions at $s = 1$. The joint compatibility Eqs. (2.37) provide 14 more at $s = 0$, say, by relating $\bar{r}^{(\alpha)}(0)$, $(q_o^{(\alpha)}(0), \bar{q}^{(\alpha)}(0))$ to $\bar{r}^{(1)}(0), (q_o^{(1)}(0), \bar{q}^{(1)}(0))$ for $\alpha = 2, 3$. The joint equilibrium Eqs. (2.39) together with (2.40) account for 7 more—for a total of 21 boundary conditions at $s = 0$. Altogether, we have 42 boundary conditions. This is precisely the number required for
the boundary value problem comprising (1.12), (1.17) for each rod, totaling 39 first-order differential equations in 42 unknowns (including the three dummy parameters $\mu^{(j)}$, $j = 1, 2, 3$). Note that we could easily express the system as 42 differential equations by simply appending $\dot{\mu}^{(j)} = 0$, $j = 1, 2, 3$.

We now discuss the results for the full structure. The symmetry-preserving solutions obtained, associated with irrep $\gamma^{(1)}$, are depicted in Fig. 2a. Surprisingly, the results include not only the primary path but also a symmetry-preserving branch of bifurcating solutions. Sample deformed configurations of the structure along each solution path are also given in Fig. 2b. Symmetry-preserving bifurcation is not “generic,” cf. (Golubitsky et al. 1988). Here the phenomenon arises on account of the employed constitutive law summarized in Table 1, which corresponds to a realistic model for engineering rods: The bending and twisting stiffnesses are several orders of magnitude smaller than the axial and shear stiffnesses, i.e., the rods are essentially inextensible and unshearable. As such, all three rods “buckle” in flexure simultaneously under compression, giving rise to the symmetry-preserving bifurcation. The same phenomenon is well documented for such a tripod comprising inextensible rods with pin-jointed connections (Britvec 1973).

The analysis of the full structure via AUTO also reveals a symmetry-breaking bifurcation associated with irrep $\gamma^{(2)}$. The primary and bifurcating solution branches along with a sample configuration on the latter are depicted in Fig. 3. The associated configurations maintain only $C_3$ symmetry. We observe that the bifurcation load occurs at a much smaller value than that of the symmetry-preserving bifurcation. We remark that the projected curve in Fig. 3 appears to show a double intersection at the bifurcation point on the right. In fact, the flat, upper part of the curve shown there does not actually contain the bifurcation point. Another symmetry-breaking bifurcation of
Fig. 3  a Principal path (black), bifurcation points and first bifurcated branch (red) corresponding to bifurcations belonging to the non-trivial 1D irrep (2). Empty square markers denote bifurcation points while full circles denote limit points. b Corresponding deformed configuration (in red) plotted against the undeformed configuration (in black), perspective and top (insert) views.

the same type occurring at a higher load level is also present on the principal path, which we do not pursue here.

Double bifurcation points, associated here with irrep $\gamma(3)$, are not detected by the code AUTO. Accordingly, symmetry reduction via (2.29), (2.32), rendering the bifurcation simple, is needed. As discussed above, we choose the subgroup $\Sigma = \{I, E\} \cong Z_2$, corresponding to reflection symmetry about the plane $span\{i_1, i_3\}$, cf. Fig. 1. Our approach is facilitated by working with the substructure comprising rods 1 and 2, accompanied by reflection conditions imposed at the joint A. To begin, we note that the fixed boundary conditions (2.39) for rods 1 and 2 are unchanged. In view of (2.4) and (2.10), we use (2.10) and (2.14) to deduce

$$\mathbf{Er}_A = \mathbf{r}_A \quad \text{and} \quad -\mathbf{Eq}_A = \mathbf{q}_A,$$

(2.41)

for the reduced problem (2.32). Then, again by (2.4) and (2.10), we employ (2.21) to find

$$r_2^{(1)}(0) = q_1^{(1)}(0) = q_3^{(1)}(0) = 0.$$  

(2.42)

In keeping with the formulation of Healey and Mehta (2005), we also require

$$(q_0^{(1)}(0))^2 + (q_2^{(1)}(0))^2 = 1.$$  

(2.43)

The conditions for rod 2 follow similarly. From (2.1) and (2.35), it follows that $\mathbf{e}^{(2)} = \mathbf{R}_{2\pi/3}Q_i\ell$, $\ell = 1, 2, 3$, and thus, $\mathbf{r}^{(2)} = r_k^{(2)}\mathbf{R}_{2\pi/3}Q_i\ell$. Then, (2.21) and (2.41) imply $i_2 \cdot \mathbf{r}^{(2)}(0) = i_2 \cdot [\mathbf{R}_{2\pi/3}Q_i\ell]r_k^{(2)}(0) = 0$, leading to

$$\sqrt{3}r_1^{(2)} + 2r_2^{(2)} + 3r_3^{(2)} = 0.$$  

(2.44)
In the same manner using (2.41)\textsubscript{2}, we obtain
\[ 2q_1^{(2)}(0) - \sqrt{3}q_2^{(2)}(0) = 0, \quad 3q_2^{(2)}(0) - 2q_3^{(2)}(0) = 0. \quad (2.45) \]

Again, we enforce (1.15) at \( s = 0 \), viz.
\[ (q_0^{(2)}(0))^2 + 4(q_2^{(2)}(0))^2 = 1, \quad (2.46) \]

where we have made use of (2.45).

From (2.26)\textsubscript{2}, the reduced problem (2.32) delivers \( n^{(3)} = En^{(2)} \) and \( m^{(3)} = -Em^{(2)} \). The joint equilibrium Eqs. (2.8)\textsubscript{2} then read
\[ n^{(1)}(0) + (I + E)n^{(2)}(0) = \lambda i_3, \quad m^{(1)}(0) + (I - E)m^{(2)}(0) = 0. \quad (2.47) \]

Finally, we express (2.47) relative to the fixed global basis \( \{i_1, i_2, i_3\} \). Employing (2.1)\textsubscript{2}, (2.11) and (2.36), we find
\[
\begin{bmatrix}
R^{(1)}(q^{(1)}(0))n^{(1)}(0) + ([I] + [E])[R_{2\pi/3}[Q][R^{(2)}(q^{(2)}(0))])n^{(2)}(0) = \\
[Q][R^{(1)}(q^{(1)}(0))]m^{(1)}(0) + ([I] - [E])[R_{2\pi/3}[Q][R^{(2)}(q^{(2)}(0))])m^{(2)}(0) = 0.
\end{bmatrix}
\quad (2.48)
\]

Note that (2.42)-(2.46) and (2.48) comprise 14 boundary conditions at \( s = 0 \). In addition, the fixed boundary conditions (2.39) for rods 1 and 2 specify 14 more at \( s = 1 \), for a total of 28 boundary conditions as required for the analysis of two rods. We employ AUTO for the reduced problem.

The numerical solution paths for \( Z_2 \)-symmetric configurations are presented in Fig. 4. As in the previous two cases, the principal, symmetry-preserving path is obtained, and the first bifurcating solution branch, breaking \( C_{3v} \) to \( Z_2 \) symmetry, is depicted in Fig. 4a. As previously predicted, the bifurcation is transcritical (asymmetrical). Thus, the two “sides” of the bifurcating solution path are visible in the projected solution curve in Fig. 4a. Deformed configurations of each side of the bifurcating path are displayed in 4(b), where the blue shade of each is associated with that shade depicted in Fig. 4a. As discussed before, there are two other bifurcating solution branches equivalent to the one reported here (say, generated by rotations). Another symmetry-breaking bifurcation of the same type but at a higher load level is also present on the principal path, which we do not pursue here.

Our results for the tripod are summarized in Fig. 5. We note that the double bifurcation point, missed without symmetry reduction, is critical for this particular structure. The primary path is stable between \( \lambda = 0 \) and \( \lambda = 12 \), after which stability is lost. The transcritical bifurcating solution is also locally unstable, and the simple bifurcations previously discussed are all unstable.

Fig. 5 Summary of primary bifurcating solution paths

4 A Space-Frame Dome

Next, we consider the hexagonal space-frame dome depicted in Fig. 6. We assume that each of the joints A-G is rigid or “welded.” Each of the twenty-four rods comprising the dome is straight and prismatic with a reflection-symmetric cross section with respect to planes perpendicular to span \( \{i_1, i_2\} \). The material properties and cross section of each rod are the same. Each of the joints A-G carries an external load of \(-\lambda i_3\). Each of the six supports of the structure is clamped. Accordingly, the system possesses the
complete symmetry group

\[ C_{6v} = \{ R_{k\pi/3}, ER_{k\pi/3} : k = 1, 2, ..., 6 \}, \quad (3.1) \]

where \( E \) is the reflection as defined in Sect. 1 and \( R_{\pi/3} \) is the proper, clockwise rotation about the global axis \( i_3 \).

We employ the same methodology employed in Sect. 2 for the tripod. In this case, we require twenty-four placement and twenty-four unit quaternion fields to describe a configuration. We designate the rods via the numbering scheme shown in Fig. 6. Similar to (2.10), a configuration is uniquely specified by the fields

\[ u := \left( r^{(1)}, q^{(1)}, r^{(2)}, q^{(2)}, ..., r^{(12)}, q^{(12)} ; r^{(13)}, q^{(13)}, ..., r^{(18)}, q^{(18)} ; r^{(19)}, q^{(19)}, ..., r^{(24)}, q^{(24)} \right). \quad (3.2) \]

Note that we group together the deformation fields in (3.2) for rods of the same type, with each group separated by semi-colons. The support rods appear in the first
group, the top rods next, and the middle rods (shown in blue in Fig. 6) last. The fields for the top and support rods are each defined over the interval \([0, \sqrt{37}]\), while each of the middle-rod fields are defined on \([0, 6]\). We orient each rod, defining the local coordinate system, as follows: Each of the top rods “starts” at joint A. The middle rods are oriented clockwise about \(i_3\), and the support rods have their origins at the joints B-G, respectively.

The total potential energy of the structure is given by

\[
\mathcal{V}[\lambda, \mathbf{u}] = \mathcal{U}[\mathbf{u}] + \lambda (r_A + r_B + \ldots + r_G) \cdot i_3, \tag{3.3}
\]

where

\[
\mathcal{U}[\mathbf{u}] := \sum_{j=1}^{18} \int_0^{\sqrt{37}} W((\mathbf{R}^{(j)})^T \mathbf{r}^{(j)}, [\mathbf{R}^{(j)}]^T \kappa^{(j)}) dx + \sum_{j=19}^{24} \int_0^6 W([\mathbf{R}^{(j)}]^T \mathbf{r}^{(j)}, [\mathbf{R}^{(j)}]^T \kappa^{(j)}) dx,
\]

and \(W : (0, \infty) \times \mathbb{R}^5 \rightarrow \mathbb{R}\) is the stored energy function, common to each of the rods. We assume fixed boundary support conditions for members 1-12, similar to (2.5)\(_1\) and (2.10)\(_3\), and joint compatibility, as in (2.4)\(_1\) and (2.10)\(_2\). We give a sampling of both:

**Boundary conditions:**

\[
\mathbf{r}^{(11)}(\sqrt{37}) = \mathbf{r}^{(12)}(\sqrt{37}) = -6\sqrt{3}i_2 - 2i_3, \quad q^{(11)}(\sqrt{37}) = q^{(12)}(\sqrt{37}) = (1, 0). \tag{3.4}
\]

**Compatibility at joint A:**

\[
\mathbf{r}^{(13)}(0) = \mathbf{r}^{(14)}(0) = \ldots = \mathbf{r}^{(18)}(0), \quad q^{(13)}(0) = q^{(14)}(0) = \ldots = q^{(18)}(0). \tag{3.5}
\]

The first-variation conditions for the potential energy deliver the equilibrium equations as in (2.8)\(_1\),

\[
\dot{\mathbf{n}}^{(j)} = 0 \text{ and } \ddot{\mathbf{m}}^{(j)} + \mathbf{r}^{(j)} \times \mathbf{n}^{(j)} = 0 \text{ in } (0, \sqrt{37}), j = 1, 2, \ldots, 18; \text{ in } (0, 6), j = 19, \ldots, 24, \tag{3.6}
\]

and joint equilibrium, as in (2.8)\(_2\), at each of the joints A-G. For example, equilibrium at joint B reads

\[
\mathbf{n}^{(17)}(\sqrt{37}) + \mathbf{n}^{(22)}(6) + \mathbf{n}^{(23)}(0) + \mathbf{n}^{(8)}(0) + \mathbf{n}^{(9)}(0) = -\lambda i_3, \quad \tag{3.7}
\]

To properly describe the symmetry group action on configuration space in terms of the two generators of \(C_{6v}\), viz. \(R_{\pi/3}\) and \(E\), we need to account for the orientation of the continuous “ring” of rods 19–24. Let \(\tau \in \mathbb{R}\) mod 36 denote the continuous
arc length of the ring, oriented clockwise starting at location B on rod 23, and let \( \vartheta \in \mathbb{R} \mod 2\pi \) denote the clockwise angle such that \( r = 6 \sin \vartheta / \sin (2\pi/3 - \vartheta) \) for \( 0 \leq \vartheta \leq \pi/3 \), etc. We parametrize the ring via \( \vartheta \) without changing the symbol of the dependent variable. Borrowing the representation for the elastic ring presented in Healey 1988b, we then define

\[
T_{R_{\pi/3}} u := (R_{\pi/3} r^{(12)}, R_{\pi/3} q^{(12)}, R_{\pi/3} r^{(1)}, R_{\pi/3} q^{(1)}, R_{\pi/3} r^{(2)}, R_{\pi/3} q^{(2)}, \ldots, R_{\pi/3} r^{(11)}, R_{\pi/3} q^{(11)}; \\
R_{\pi/3} r^{(18)}, R_{\pi/3} q^{(18)}, R_{\pi/3} r^{(13)}, R_{\pi/3} q^{(13)}, \ldots, R_{\pi/3} r^{(17)}, R_{\pi/3} q^{(17)}; \\
R_{\pi/3} r^{(24)}(\vartheta - \pi/3), R_{\pi/3} q^{(24)}(\vartheta - \pi/3), R_{\pi/3} r^{(19)}(\vartheta - \pi/3), R_{\pi/3} q^{(19)}(\vartheta - \pi/3), \ldots, \\
R_{\pi/3} r^{(23)}(\vartheta - \pi/3), R_{\pi/3} q^{(23)}(\vartheta - \pi/3)),
\]

(3.8)

Observe that the reflection reverses the orientations of rods 19–24 in this case, which explains the appearance of \( -\vartheta \) in the arguments of those actions. The group actions on the support rods and the top rods do not affect orientations and thus do not act on the independent variable. As in Sect. 2, the total potential energy (3.3) is invariant under the group action, viz.

\[
V[\lambda, T_G u] = V[\lambda, u] \text{ for all } G \in C_{6v}.
\]

(3.9)

Although we omit the tedious details, we observe that the invariance of the internal energy \( I \) is a consequence of the following: Given a configuration field \( u \) as in (3.2), then \( T_G u, G \in C_{6v} \), can be interpreted as either a rotation by an integer multiple of \( \pi/3 \) or a reflection of the configuration across a plane perpendicular to \( \text{span}\{i_1, i_2\} \) making an angle of an integer multiple of \( \pi/6 \) with respect to \( \text{span}\{i_1, i_3\} \). In each of the three levels of the structure, the rods are all identical and have reflection symmetry in their cross sections. Thus, the internal energy is invariant. For the loading term in (3.3), we deduce from the generators (3.8) that

\[
r_A + r_B + \ldots + r_G \to R_{\pi/3}(r_A + r_B + \ldots + r_G)
\]

and

\[
r_A + r_B + \ldots + r_G \to E(r_A + r_B + \ldots + r_G),
\]

respectively. Of course, \( R_{\pi/3}^T i_3 = E_i = i_3 \), and the invariance follows.
As in Sect. 2, the first variation in the potential energy and integration by parts deliver the strong form of the equilibrium equations, again denoted abstractly by (2.29). Moreover, the equivariance of the equilibrium equations follows from (3.9) as in Proposition 2.2, viz.

$$f(\lambda, T_G u) = \tilde{T}_G f(\lambda, u) \text{ for all } G \in C_{6v},$$  \( (3.10) \)

where the generators of the action \( \tilde{T}_G \) in (3.10) are defined similar to (3.8), e.g., for

$$\sigma := (n^{(1)}, m^{(1)}, n^{(2)}, m^{(2)}, \ldots, n^{(12)}, m^{(12)}; n^{(13)}, m^{(13)}, \ldots, n^{(18)}, m^{(18)}; n^{(19)}, m^{(19)}, \ldots, n^{(24)}, m^{(24)}).$$  \( (3.11) \)

The symmetry group \( C_{6v} \) has six irreducible representations (McWeeny 2002), the generators of which are:

$$\gamma^{(1)}_{R_{\pi/3}} = \gamma^{(1)}_E = 1,$$
$$\gamma^{(2)}_{R_{\pi/3}} = -\gamma^{(2)}_E = 1,$$
$$\gamma^{(3)}_{R_{\pi/3}} = -\gamma^{(3)}_E = -1,$$
$$\gamma^{(4)}_{R_{\pi/3}} = \gamma^{(4)}_E = -1,$$
$$\gamma^{(5)}_{R_{\pi/3}} = \frac{1}{2} \begin{bmatrix} -1 & \sqrt{3} \\ \sqrt{3} & -1 \end{bmatrix},$$
$$\gamma^{(6)}_{R_{\pi/3}} = \frac{1}{2} \begin{bmatrix} 1 & \sqrt{3} \\ -\sqrt{3} & 1 \end{bmatrix}. $$  \( (3.12) \)

As in Sect. 2, the first irrep \( \gamma^{(1)} \) is associated with symmetry-preserving configurations. The 1-dimensional irreps (2)-(4) are each associated with potential 1-dimensional symmetry-breaking bifurcations. As before, the second irrep \( \gamma^{(2)} \) is associated with configurations having pure rotational symmetry without reflections symmetry, viz. \( C_{6v} \) symmetry. The other two irreps \( \gamma^{(3)} \) and \( \gamma^{(4)} \) are associated with configurations having only \( C_{3v} \) symmetry (with different orientations). This can be deduced from the observations \( \gamma^{(3)}_{R_{2\pi/3}} = \gamma^{(3)}_E = 1 \) and \( \gamma^{(4)}_{R_{2\pi/3}} = \gamma^{(4)}_E \gamma^{(4)}_{R_{\pi/3}} = \gamma^{(4)}_{ER_{\pi/3}} = 1 \). In each case, these are the generators of a 1-dimensional representation of \( D_3 \cong C_{3v} \). In the potential case of bifurcation associated with the irreps \( (3.12)_{2-4} \), we expect pitchforks in each case. This follows from the equivariance of the bifurcation equation under the representation, which induces oddness in the amplitude variable. As noted in Sect. 2, the software AUTO detects and computes such simple bifurcations—
particular, without symmetry reduction. Again, we take a practical approach here and analyze to the full structure. For each rod in the framework, we assume the material properties summarized in Table 1, and we rescale according to (2.34), where $L$ denotes the length of the particular rod. In this way, we obtain a system of Eqs. (1.12), (1.17) for each rod, all defined over the unit interval, the form of which is necessary for the use of AUTO. The rod equilibrium equations are combined with joint compatibility equations and joint equilibrium equations, samples of which are provided in (3.5) and (3.7), respectively. As in the case of the tripod of Sect. 2, the field equations for each rod need to be expressed with respect to its local basis, the details of which we omit here. In this case, we also employ the modified bifurcation criterion proposed in Glowacki (2016), enabling the code to work accurately for very large boundary value problems.

The results for the full structure (no symmetry reductions) are now presented. The symmetry-preserving primary solution branch is depicted in Fig. 7, and a few sample configurations corresponding to various solutions along it are provided in Fig. 8. In this case, there are no symmetry-preserving bifurcations. In particular, the solution curve does not have self-intersections, which only arise in the projection shown in Fig. 7. Several symmetry-breaking bifurcations are indicated in Fig. 7. We discuss

![Fig. 7 Primary solution branch for the hexagonal dome](image1)

![Fig. 8 Symmetry-preserving configurations along the primary path](image2)
only those occurring on the first “ascending” part of the solution path. The first at \(\lambda = 1.15\) is a subcritical pitchfork. The global solution path is shown in Fig. 9 along with a typical configuration. In particular, we observe that solutions on the bifurcating branch maintain \(C_{3v}\) symmetry associated with the irrep \(\gamma^{(4)}\). The latter follows from the observation that the configurations possess a reflection symmetry corresponding to \(T_E T_R_{\pi/3} = T_E R_{\pi/3}\). Remarkably, the second solution branch, bifurcating at \(\lambda = 1.22\), is of the same type, viz. a \(C_{3v}\)-symmetric subcritical pitchfork also associated with \(\gamma^{(4)}\). The global solution path and a typical configuration are shown in Fig. 10. Finally, the third solution path, bifurcating at \(\lambda = 1.31\), and a typical configuration are given in Fig. 11. These configurations also maintain \(C_{3v}\) symmetry associated with irrep \(\gamma^{(3)}\); the configurations possess a reflection symmetry corresponding to \(T_E\).

---

**Fig. 9** Primary solution path and first \(C_{3v}\)-symmetric pitchfork bifurcation at \(\lambda = 1.15\) and a typical configuration

**Fig. 10** Primary solution path and second \(C_{3v}\)-symmetric pitchfork bifurcation at \(\lambda = 1.22\) and a typical configuration
Double bifurcation points for the complete structure, potentially associated here with the 2-dimensional irreps $\gamma^{(5)}$ and $\gamma^{(6)}$, cannot be detected directly by AUTO; symmetry reduction is required. The irrep $\gamma^{(6)}$ is a faithful representation of $D_6(\cong C_{6v})$ on $\mathbb{R}^2$; $\gamma^{(5)}$ is not. But a comparison of the latter with (2.33) reveals that $\gamma^{(5)}$ is associated (faithfully) with the symmetry $D_3(\cong C_{3v})$ on $\mathbb{R}^2$, but with each element of the group appearing twice. As discussed in Sect. 2, there are three equivalent ways to break $D_3-$ symmetry (to that of an isosceles triangle) leaving reflection symmetry. Accordingly, if there is bifurcation associated with $\gamma^{(5)}$, we expect three equivalent bifurcating branches; it is enough to compute only one of these. As discussed in Sect. 2, we expect such a bifurcation to be transcritical.

Symmetry-breaking bifurcation associated with $\gamma^{(6)}$ is more interesting: There are two nonequivalent ways to break $D_6$ symmetry (that of a hexagon) leaving reflection symmetry. One of the symmetry subgroups comprises the $2 \times 2$ identity matrix and $\gamma_E^{(6)}$, while the other consists of the identity and $\gamma_E^{(6)} \gamma_{R_\pi} = \gamma_{ER_\pi} = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}$. Notice that the former has a reflection symmetry about a line connecting two opposing vertices of the hexagon, while the latter has a reflection symmetry about that connecting two opposing edges of the hexagon. Each of these, in turn, can be accomplished in two other equivalent ways. Thus, if there is bifurcation associated with $\gamma^{(6)}$, then we expect two non-equivalent bifurcating branches, each associated with two other equivalent branches—for a total of six bifurcating branches. Any such bifurcation is expected to be a pitchfork; the equivariance of the bifurcation equations under $\gamma^{(6)}$ implies oddness in the amplitude of the reduced 1D bifurcation equation (Golubitsky et al. 1988).

To capture potential double bifurcations here, we require reduced problems (2.29), (2.32) such that the bifurcations become simple, as in the $Z_2 -$ preserving solutions of Sect. 2. The main task is to obtain substructures (and boundary conditions) that admit only simple bifurcations. As in Sect. 2, we restrict the symmetry reductions

---

**Fig. 11** Primary solution path and third $C_{3v}$-symmetric pitchfork bifurcation at $\lambda = 1.31$ and a typical configuration

![Graph showing primary solution path and third $C_{3v}$-symmetric pitchfork bifurcation at $\lambda = 1.31$.]
only at the joints A-G. Based on the observations discussed in the paragraph above, it is apparent that substructures maintaining only reflection symmetry are required. The first substructure we employ is shown in Fig. 12.

The boundary conditions at the supports and the joint compatibility and equilibrium conditions at joints D, E and F are the same as before (for the complete structure). The boundary conditions at joint A and at the newly exposed points P, Q arise from the reflection symmetry associated with the reduced problem. In view of (3.1), recall that $K := ER_{\pi} \in C_{6v}$ is a reflection across the plane $\text{span}\{i_2, i_3\}$. It is not hard to see that $T_K = T_{ER_{\pi}} = T_E T_{R_\pi}$, and from (3.8), we find

$$T_K u := (Kr^{(10)}, Kq^{(10)}, Kr^{(9)}, Kq^{(9)}, Kr^{(8)}, Kq^{(8)}, Kr^{(7)}, Kq^{(7)}, Kr^{(6)}, Kq^{(6)}, Kr^{(5)}, Kq^{(5)}, Kr^{(4)}, Kq^{(4)}, ..., Kr^{(1)}, Kq^{(1)}, Kr^{(12)}, Kq^{(12)}, Kr^{(11)}, Kq^{(11)}, Kr^{(18)}, Kq^{(18)}, Kr^{(17)}, Kq^{(17)}, Kr^{(16)}, Kq^{(16)}, ..., Kr^{(13)}, Kq^{(13)};$$

$$Kr^{(23)}(\pi - \vartheta), Kq^{(23)}(\pi - \vartheta), Kr^{(22)}(\pi - \vartheta), Kq^{(22)}(\pi - \vartheta), Kr^{(21)}(\pi - \vartheta), Kq^{(21)}(\pi - \vartheta), Kr^{(20)}(\pi - \vartheta), Kq^{(20)}(\pi - \vartheta), Kr^{(19)}(\pi - \vartheta), Kq^{(19)}(\pi - \vartheta), Kr^{(24)}(\pi - \vartheta), Kq^{(24)}(\pi - \vartheta)).$$

(3.13)

where $Kq := (q_o, -Kq)$ Similarly, we have
\[^{\nu}\]K\sigma := (Kn^{(10)}, -Km^{(10)}, Kn^{(9)}, -Km^{(9)}, Kn^{(8)}, -Km^{(8)}, Kn^{(7)}, -Km^{(7)}, \ldots, \\
K_n^{(1)}, -Km^{(1)}, Kn^{(12)}, -Km^{(12)}, Kn^{(11)}, -Km^{(11)}, \\
K_n^{(18)}, -Km^{(18)}, Kn^{(17)}, -Km^{(17)}, \ldots, Kn^{(13)}, -Km^{(13)}, \\
K_n^{(23)}(\pi - \vartheta), -Km^{(23)}(\pi - \vartheta), Kn^{(22)}(\pi - \vartheta), -Km^{(22)}(\pi - \vartheta), \\
K_n^{(21)}(\pi - \vartheta), -Km^{(21)}(\pi - \vartheta), Kn^{(20)}(\pi - \vartheta), -Km^{(20)}(\pi - \vartheta), \\
K_n^{(19)}(\pi - \vartheta), -Km^{(19)}(\pi - \vartheta), Kn^{(24)}(\pi - \vartheta), -Km^{(24)}(\pi - \vartheta)).
\]

(3.14)

Notice that the “slots” for rods 21 and 24 do not change in the actions (3.13), (3.14).

We choose the subgroup \( \Sigma = (I, K) \) for the construction of the reduced problem (2.32). From (3.2) and (3.13), it then follows that \((Kn^{(21)}(\pi - \vartheta), (q_o, -Kq)^{(21)}(\pi - \vartheta)) \equiv (r^{(21)}(\vartheta), (q_o, q)^{(21)}(\vartheta))\). Evaluating this at mid-point \(P (\vartheta = 3\pi/2 = -\pi/2)\) gives \((Kr, (q_oP, -Kq_P)) \equiv (r_P, (q_oP, q_P))\), implying

\[
i_1 \cdot r_P = 0, i_\alpha \cdot q_P = 0, \\
i_1 \cdot r_P = 0, i_\alpha \cdot q_Q = 0, \alpha = 2, 3,
\]

(3.15)

the second set of which follows from the same arguments applied to rod 24 (evaluated at \(\vartheta = \pi/2\)). Similar conditions result at joint A. For instance, (3.2) and (3.13) via the reduced problem imply that \((Kr^{(17)}(s), (q_o, -Kq)^{(17)}(s)) \equiv (r^{(14)}(s), (q_o, q)^{(14)}(s))\). Evaluating this at point A \((s = 0)\) gives \((Kr_A, (q_oA, -Kq_A)) \equiv (r_A, (q_oA, q_A))\), implying

\[
i_1 \cdot r_A = 0, i_\alpha \cdot q_A = 0, \alpha = 2, 3.
\]

(3.16)

The equilibrium conditions at P, Q and A follow from joint equilibrium and reflection symmetry. For example, at mid-point Q we generally have the equilibrium conditions \(n_Q + n_{Q^+} = 0\) and \(m_Q + m_{Q^+} = 0\), where \(n_Q, m_Q\) refer to the force and moment resultant on the substructure, while \(n_{Q^+}, m_{Q^+}\) refer to that on the right substructure. From (3.11)1 and (3.14), the reduced problem implies \((Kn^{(24)}(\pi - \vartheta), -Km^{(24)}(\pi - \vartheta)) \equiv (n^{(24)}(\vartheta), m^{(24)}(\vartheta))\). Evaluating this at the mid-point Q \((\vartheta = \pi/2)\), we find \((Kn_Q, -Km_Q) \equiv (n_{Q^+}, m_{Q^+})\). Thus, the equilibrium conditions now read \(n_Q = -K_n Q\) and \(m_Q = K_m Q\), implying

\[
i_1 \cdot m_Q = 0, i_\alpha \cdot n_Q = 0, \\
i_1 \cdot m_P = 0, i_\alpha \cdot n_P = 0, \alpha = 2, 3,
\]

(3.17)

the second of which follows from the same argument applied to rod 21. Balance of force and moments at joint A \((s = 0)\) are generally given by

\[
n^{(13)}(0) + n^{(14)}(0) + n^{(15)}(0) + n^{(16)}(0) + n^{(17)}(0) + n^{(18)}(0) = -\lambda i_3, \\
m^{(13)}(0) + m^{(14)}(0) + m^{(15)}(0) + m^{(16)}(0) + m^{(17)}(0) + m^{(18)}(0) = 0,
\]

(3.18)
respectively. For the reduced problem via (3.11) and (3.14), we deduce
\[ n^{(16)}(0) = Kn^{(15)}(0), \quad m^{(16)}(0) = -Km^{(15)}(0), \quad n^{(17)}(0) = Kn^{(14)}(0), \quad m^{(17)}(0) = -Km^{(14)}(0), \quad n^{(18)}(0) = Kn^{(13)}(0), \quad \text{and} \quad m^{(18)}(0) = -Km^{(13)}(0). \]
Hence, (3.18) reduces to
\[
[I + K](n^{(13)}(0) + n^{(14)}(0) + n^{(15)}(0)) = -\lambda i_3,
\]
\[
[I - K](m^{(13)}(0) + m^{(14)}(0) + m^{(15)}(0)) = 0.
\] (3.19)

Note that \( \text{rank} [I + K] = 2 \) and \( \text{rank} [I - K] = 1 \), i.e., (3.19) yields 3 scalar equations. Conditions (3.15)-(3.17) and (3.19) provide the extra conditions needed for maintaining reflection symmetry on the substructure of Fig. 12. In order to implement AUTO, all rods in the half-structure are rescaled according to (2.34). This includes the half-lengths of rods DP and FQ, which need to be rescaled according to (2.34) with \( L = 3 \). As before, the field equations for each rod in the half-structure need to be written with respect to their respective local coordinate system, the details of which we omit.

The results for the half-structure are shown in Figs. 13 and 14. As expected, the simple \( C_3 \) symmetric bifurcations at \( \lambda = 1.15 \) and \( \lambda = 1.22 \) (see Figs. 9 and 10, respectively) are captured. The first new bifurcation detected occurs at \( \lambda = 1.26 \), which is transcritical; we deduce that it is associated with irrep \( \gamma^5 \). A typical configuration along with the solution path is shown in Fig. 13. Along this branch, the deformed structure appears to possess \( C_2 \), i.e., rectangular symmetry. This will be confirmed shortly. The second new bifurcation occurring at \( \lambda = 1.42 \) is a subcritical pitchfork. Hence, it is associated with irrep \( \gamma^6 \). The computed branch at hand, depicted in Fig. 14, is one of two non-equivalent solution branches occurring at that bifurcation point. This too will be confirmed shortly. A typical configuration along the computed solution path is also given in Fig. 14.

Next, we consider the reduced problem (2.29), (2.32) corresponding to subgroup \( \Sigma = \{ I, E \} \); the associated substructure chosen here is depicted in Fig. 15. As before,
Fig. 14 Pitchfork double bifurcation point at $\lambda = 1.42$ and typical configuration with $Z_2$ symmetry.

Fig. 15 Top view of the substructure associated with symmetry group $\Sigma = \{I, E\}$.

The boundary conditions at the supports and the interior joint compatibility and equilibrium conditions at joints F and G are the same used in the analysis of the complete structure. The boundary conditions at joints A, B, and E arise from the reflection symmetry associated with the reduced problem. For instance, (3.2) and (3.8)$_2$ imply $\left(\text{Er}^{(22)}(s), (q_o, -Eq)^{(22)}(s)\right) = (r^{(23)}(s), (q_o, q)^{(23)}(s))$. Evaluating this at $s = 0$, we deduce $(\text{Er}_B, (q_oB, -Eq_B)) = (r_B, (q_oB, q_B))$, and thus,

$$i_2 \cdot r_B = 0, \ i_\alpha \cdot q_B = 0, \ \alpha = 1 \& 3.$$  \hspace{1cm} (3.20)

Similar considerations lead to the same type of conditions at joints A and E:

$$i_2 \cdot r_A = 0, \ i_\alpha \cdot q_A = 0,$$

$$i_2 \cdot r_E = 0, \ i_\alpha \cdot q_E = 0, \ \alpha = 1 \& 3.$$  \hspace{1cm} (3.21)
Force and moment balance at joint E generally read

\[
\begin{align*}
\mathbf{n}^{(19)}(6) + \mathbf{n}^{(20)}(0) + \mathbf{n}^{(2)}(0) + \mathbf{n}^{(3)}(0) + \mathbf{n}^{(14)}(\sqrt{37}) &= -\lambda \mathbf{i}_3, \\
\mathbf{m}^{(19)}(6) + \mathbf{m}^{(20)}(0) + \mathbf{m}^{(2)}(0) + \mathbf{m}^{(3)}(0) + \mathbf{m}^{(14)}(\sqrt{37}) &= 0,
\end{align*}
\]

respectively, where we employ the local arc-length coordinates of each rod. For the reduced problem, conditions (3.11) imply \(\mathbf{n}^{(20)}(0) = \mathbf{E} \mathbf{n}^{(19)}(6), \mathbf{m}^{(20)}(0) = -\mathbf{E} \mathbf{m}^{(19)}(6), \mathbf{n}^{(3)}(0) = \mathbf{E} \mathbf{n}^{(2)}(0), \mathbf{m}^{(3)}(0) = -\mathbf{E} \mathbf{m}^{(2)}(0), \) and \(\mathbf{E} \mathbf{n}^{(14)}(6) = \mathbf{n}^{(14)}(6). \) Thus, (3.22) becomes

\[
\begin{align*}
[I + \mathbf{E}](\mathbf{n}^{(19)}(6) + \mathbf{n}^{(2)}(0) + \mathbf{n}^{(14)}(\sqrt{37})/2) &= -\lambda \mathbf{i}_3, \\
[I - \mathbf{E}](\mathbf{m}^{(19)}(6) + \mathbf{m}^{(2)}(0) + \mathbf{m}^{(14)}(\sqrt{37})/2) &= 0.
\end{align*}
\]

Beginning with the general equilibrium conditions (3.7), the reflection symmetry of the reduced problem at joint B implies

\[
\begin{align*}
[I + \mathbf{E}](\mathbf{n}^{(23)}(0) + \mathbf{n}^{(9)}(0) + \mathbf{n}^{(17)}(\sqrt{37})/2) &= -\lambda \mathbf{i}_3, \\
[I - \mathbf{E}](\mathbf{m}^{(23)}(0) + \mathbf{m}^{(9)}(0) + \mathbf{m}^{(17)}(\sqrt{37})/2) &= 0.
\end{align*}
\]

Finally, (3.18) and reflection symmetry lead to

\[
\begin{align*}
[I + \mathbf{E}](\mathbf{n}^{(13)}(0) + \mathbf{n}^{(18)}(0) + [\mathbf{n}^{(14)}(0) + \mathbf{n}^{(17)}(0)]/2) &= -\lambda \mathbf{i}_3, \\
[I - \mathbf{E}](\mathbf{m}^{(13)}(0) + \mathbf{m}^{(18)}(0) + [\mathbf{m}^{(14)}(0) + \mathbf{m}^{(17)}(0)]/2) &= 0.
\end{align*}
\]

Note that rank \([\mathbf{I} + \mathbf{E}] = 2\) and rank \([\mathbf{I} - \mathbf{E}] = 1\). Thus, each of (3.23)-(3.25) represent 3 scalar equations.

The results for the half-structure of Fig. 15 are as follows: As expected, the simple \(C_{3v}\) symmetric solution branch, bifurcating at \(\lambda = 1.31\) and shown in Fig. 11, is again found. Moreover, precisely the same transcritical bifurcation path depicted in Fig. 13 is obtained. This confirms the \(C_{2v}\) symmetry of the configurations along it. The underlying group-theoretic reasoning for this is provided in Appendix 2. Next, a new bifurcating pitchfork branch of solutions is detected at \(\lambda = 1.42\), which is given in Fig. 16 along with a typical configuration. Observe that this solution branch is distinct from that shown in Fig. 14; e.g., each possesses a distinct reflection symmetry. This confirms that the double bifurcation point at \(\lambda = 1.42\) is associated with irrep \(\gamma^{(6)}\).

Finally, we deduce some local stability information via the usual exchange-of-stability arguments (Kielhöfer 2012). Stable here means that the equilibrium is a local minimum of the total potential energy. The first ascending portion of the primary \(C_{6v}\) symmetric path between \(\lambda = 0\) and \(\lambda = 1.15\) is stable, after which stability is lost; the first subcritical \(C_{3v}\) symmetric pitchfork emanating from \(\lambda = 1.15\) is also unstable. However, the next subcritical \(C_{3v}\) symmetric bifurcation at \(\lambda = 1.22\) (precisely of the same type) regains stability as does the primary solution path between \(\lambda = 1.22\) and \(\lambda = 1.26\). Beyond that, the primary solution path and the remaining bifurcating
Fig. 16 Pitchfork double-bifurcation point at $\lambda = 1.42$ and typical configuration with $Z_2$ symmetry

solution paths—3 branches at $\lambda = 1.26$, 1 branch at $\lambda = 1.31$, and 6 branches at $\lambda = 1.42$—are all locally unstable.

5 Concluding Remarks

We present a general approach to the bifurcation analysis of elastic frameworks with symmetry in this work. While group-theoretic methods for bifurcation problems with symmetry are well known, their actual implementation in the context of Cosserat rod frameworks is not straightforward. The main difficulty arises from the nonlinear configuration space, due to the presence of (cross-sectional) rotation fields. We avoid this via the single-rod formulation of Healey and Mehta (2005), whereby the governing equations are embedded in a slightly enlarged linear space. The field equations for a framework comprise the assembly of the rods equations, supplemented by compatibility and equilibrium conditions at the joints. We establish their equivariance via the invariance of the total potential energy under the group action. Moreover, the implementation of group-theoretic methods is natural within the linear space context. All potential generic, symmetry-breaking bifurcations are a-priori predicted. We employ the numerical path-following code AUTO (Doedel et al. 2007), which can detect and compute simple, one-dimensional bifurcations. For double bifurcation points, we construct symmetry-reduced problems implemented by appropriate substructures. The double bifurcations are rendered simple, and AUTO is again applicable. We mention that the subgroup-symmetry restrictions are imposed only at the exposed joints of the substructures used in Sects. 2 and 3. In fact, the reduced problem (2.29), (2.32) impacts all exposed degrees of freedom—not just those at the exposed joints. Nonetheless, our practical approach employed here is demonstratively successful.

It is entirely possible to construct reduced problems via substructures for all simple bifurcations found as well—say for increased efficiency as in Bossavit (1986). For instance, this can be easily done for the tripod using a single rod. In the same way, each
of the simple bifurcations for the hexagonal dome can be obtained via an appropriate substructure. But there is no real need for such, given that AUTO easily handles these for the complete structure.

Our formulation is not restricted to rigid (welded) joints. As indicated in (2.6) and discussion immediately thereafter, other connection types are possible, e.g., ball in socket. Hinged connections (free rotation about one axis) and “mixed” connections at a joint are also possible. Moreover, our construction of reduced problems is not restricted to double bifurcation points; multiple bifurcation points arising from higher symmetry can be reduced in a similar manner. Finally, we point out that while our formulation is conveniently implemented via AUTO, it does not depend on it. Any two-point boundary solver—on a rod-by-rod basis, supplemented by joint equilibria and compatibility—can be employed as the basis for numerical continuation and bifurcation.

Appendix 1

Proof of Proposition 1.1

For simplicity, we suppose that the configuration of the rod is prescribed at the two ends, viz. \( r(0), R(0), r(L) \) and \( R(L) \) are specified. We consider smooth but arbitrary fields \( \eta(x), \Theta(x) \) that vanish at the end points with \( \Theta^T \equiv -\Theta \), i.e., \( \Theta \) is a skew-symmetric field. The former is an additive admissible variation for the field \( r \), in contrast to the variation in the rotation field \( R \). Rather, a finite perturbation of \( R(s) \) reads \( \exp[\varepsilon \Theta(s)]R(s) \), and an admissible first-order variation follows from \( R \to \left. \frac{d}{d\varepsilon} \exp[\varepsilon \Theta]R \right|_{\varepsilon=0} = \Theta R \). The first-variation condition for (1.6) then follows from the calculation

\[
\left. \frac{d}{d\varepsilon} \mathcal{U}[r + \varepsilon \eta, R + \varepsilon \Theta R + o(\varepsilon)] \right|_{\varepsilon=0} = 0 \quad \text{for all } \eta, \Theta \quad (4.1)
\]

From (1.6), this entails unravelling the pertinent first-order perturbations:
\[
[R + \varepsilon \Theta R + o(\varepsilon)]^T (\dot{r} + \varepsilon \dot{\eta}) = R^T \dot{r} + \varepsilon R^T (\dot{\eta} - \Theta \dot{r}) + o(\varepsilon)
\]
\[
= R^T \dot{r} + \varepsilon R^T (\dot{\eta} + \dot{r} \times \theta) + o(\varepsilon),
\]
where \( \theta = \text{axial}(\Theta) \). In addition,

\[
[\dot{R} + \varepsilon (\dot{\Theta} R + \Theta \dot{R}) + o(\varepsilon)] [R + \varepsilon \Theta R + o(\varepsilon)]^T
\]
\[
= K + \varepsilon (\dot{\Theta} + \Theta K - K \Theta) + o(\varepsilon),
\]

\(\text{axial}[K + \varepsilon (\dot{\Theta} + \Theta K - K \Theta) + o(\varepsilon)] = K + \varepsilon (\dot{\theta} + \theta \times \kappa) + o(\varepsilon),\)

and then

\[
[R + \varepsilon \Theta R + o(\varepsilon)]^T [K + \varepsilon (\dot{\Theta} + \Theta K - K \Theta) + o(\varepsilon)]
\]
\[
= R^T K + \varepsilon R^T (\dot{\Theta} + \Theta K - K \Theta) + o(\varepsilon)
\]
\[
(4.2)
\]

Returning to (4.1), we now find

\[
\langle \delta U, (\eta, \theta) \rangle := \frac{d}{d\varepsilon} U[r + \varepsilon \eta, R + \varepsilon \Theta R + o(\varepsilon)]|_{\varepsilon=0}
\]
\[
= \frac{d}{d\varepsilon} \int_0^L W(R^T \dot{r} + \varepsilon R^T (\dot{\eta} + \dot{r} \times \theta) + o(\varepsilon), R^T \kappa + \varepsilon R^T \dot{\theta} + o(\varepsilon)) dx|_{\varepsilon=0}
\]
\[
= \int_0^L \left\{ \frac{\partial W}{\partial \nu_i} (R^T \dot{r}, R^T \kappa) e_i \cdot [R^T (\dot{\eta} + \dot{r} \times \theta)] + \frac{\partial W}{\partial \kappa_i} (R^T \dot{r}, R^T \kappa) e_i \cdot R^T \dot{\theta} \right\} dx
\]
\[
= \int_0^L \left\{ n \cdot (\dot{\eta} + \dot{r} \times \theta) + m \cdot \dot{\theta} \right\} ds = 0 \text{ for all } \eta, \theta,
\]

(4.3)

where the last line follows from the use of (1.1) and (1.5). The first-variation condition (4.3) expresses the weak form of the equilibrium equations; the classical form (1.7) follows from (4.3) via integration by parts and the usual formal arguments of the calculus of variations.

\(\square\)

**Proof of Proposition 2.1**

We assume the end conditions (2.4), (2.5). In consonance with those, we consider smooth fields \( \eta^{(j)}(s), \Theta^{(j)}(s) \) satisfying

\[
\eta^{(j)}(L) = 0, \Theta^{(j)}(L) = 0, j = 1, 2, 3,
\]
\[
\eta_A := \eta^{(1)}(0) = \eta^{(2)}(0) = \eta^{(3)}(0),
\]
\[
\Theta^{(1)}(0) = \Theta^{(2)}(0) = \Theta^{(3)}(0),
\]

\(\blacklozenge\) Springer
which we use to construct admissible variations of \((\mathbf{r}^{(j)}, \mathbf{R}^{(j)}), \ j = 1, 2, 3\), respectively, as in (4.2). We express this abstractly via

\[
\tilde{\mathcal{U}}[\mathbf{u}; \mathbf{h}, \varepsilon] := \mathcal{U}(\mathbf{r}^{(1)} + \varepsilon\mathbf{\eta}^{(1)}, \mathbf{R}^{(1)} + \varepsilon\mathbf{\Theta}^{(1)}(\mathbf{R}^{(1)}, \mathbf{r}^{(2)} + \varepsilon\mathbf{\eta}^{(2)}, \mathbf{R}^{(2)} + \varepsilon\mathbf{\Theta}^{(2)}(\mathbf{R}^{(2)}, \mathbf{r}^{(3)} + \varepsilon\mathbf{\eta}^{(3)}, \mathbf{R}^{(3)} + \varepsilon\mathbf{\Theta}^{(3)}(\mathbf{R}^{(3)})) + o(\varepsilon),
\]

(4.5)

where \(\mathbf{h} := (\mathbf{\eta}^{(1)}, \mathbf{\Theta}^{(1)}, \mathbf{\eta}^{(2)}, \mathbf{\Theta}^{(2)}, \mathbf{\eta}^{(3)}, \mathbf{\Theta}^{(3)})\), with \(\mathbf{\Theta}^{(j)} = \text{axial}(\mathbf{\Theta}^{(j)})\), cf. (2.25).

Then as in (4.3), we compute the first-variation condition:

\[
\langle \delta \mathcal{V}[\mathbf{\lambda}, \mathbf{u}], \mathbf{h} \rangle := \left. \frac{d}{d\varepsilon} \mathcal{U}[\mathbf{u}; \mathbf{h}, \varepsilon] \right|_{\varepsilon=0} = \langle \delta \mathcal{U}[\mathbf{\lambda}, \mathbf{u}], \mathbf{h} \rangle + \lambda i_3 \cdot \mathbf{\eta}_A \\
= \sum_{j=1}^{3} \int_0^L \left\{ \frac{\partial W}{\partial \mathbf{r}_j} \right\} \left[ (\mathbf{R}^{(j)})(\mathbf{F}^{(j)}(\mathbf{r}^{(j)} + \varepsilon \mathbf{\eta}^{(j)} + \varepsilon \mathbf{\Theta}^{(j)} + o(\varepsilon)), (\mathbf{R}^{(j)})(\mathbf{F}^{(j)}(\mathbf{r}^{(j)} + \varepsilon \mathbf{\eta}^{(j)} + \varepsilon \mathbf{\Theta}^{(j)} + o(\varepsilon))) \right] d\varepsilon + \lambda i_3 \cdot !A = 0
\]

(4.6)

for all admissible fields \(\mathbf{\eta}^{(j)}, \mathbf{\Theta}^{(j)} = \text{axial}(\mathbf{\Theta}^{(j)}), \ j = 1, 2, 3\), satisfying (4.4); we used (1.1) and (1.4) in going from (4.6)\_1 to (4.6)\_3. The last line of (4.6) expresses the weak form of the equilibrium equations. Integration by parts yields, use of (4.4), and the usual formal arguments of the calculus of variations then deliver the field Eqs. (2.8).□

**Proof of Proposition 2.3:**

First, we note that (2.24) is trivial for the symmetry-preserving loading term: From (4.6)\_1, the first variation in the loading potential is simply \(\lambda i_3 \cdot \mathbf{\eta}_A \equiv \lambda G i_3 \cdot \mathbf{\eta}_A\) for all \(\mathbf{G} \in \mathbb{C}_{3v}\). So it’s enough to show the validity of (2.24) for the internal potential energy \(\mathcal{U}[\mathbf{\lambda}, \mathbf{u}]\). Employing (4.5) and (2.26), we compute directional derivative of the invariance conditions (2.15) (ignoring the loading term):

\[
\left. \frac{d}{d\varepsilon} \mathcal{U}(\mathbf{T}_G \mathbf{u}; \mathbf{h}, \varepsilon) \right|_{\varepsilon=0} = \left. \frac{d}{d\varepsilon} \mathcal{U}[\mathbf{u}; \mathbf{h}, \varepsilon] \right|_{\varepsilon=0} \Rightarrow
\]

(4.7)

for all \(\mathbf{G} \in \mathbb{C}_{3v}\) and for all admissible \(\mathbf{h}\). The modified action on the space of admissible variations in (4.7)\_2 arises as in (4.5)–from the conversion of skew-symmetric-matrix
actions to cross products. It is straightforward, if tedious, to verify that the transformations (2.26) generate a faithful representation of $C_{3v}$, i.e., the mapping $G \mapsto \tilde{T}_G$ is one-to-one, and

$$\tilde{T}_G \tilde{T}_H = \tilde{T}_{GH}, \tilde{T}_G^{-1} = \tilde{T}_{G^{-1}}, \tilde{T}_I = I \text{ (identity).}$$

(4.8)

Moreover, we claim that $\tilde{T}_G^* \equiv \tilde{T}_G^{-1}$ on $C_{3v}$, (4.9)

where $\tilde{T}_G^*$ denotes the adjoint operator of $\tilde{T}_G$ with respect to the inner-product (2.27). To see this, first note that

$$\langle \tilde{T}_G^* \tilde{T}_G \sigma, h \rangle = \langle \tilde{T}_G \sigma, \tilde{T}_G h \rangle = \langle \sigma, h \rangle \text{ on } C_{3v},$$

(4.10)

for all smooth fields $\sigma, h$, the second equality of which is readily verified via (2.26), (2.27). Thus, $\tilde{T}_G^*$ is a left inverse. Now let $\sigma = \tilde{T}_G \mu$ and $k = \tilde{T}_G h$ in the second part of (4.10), leading to $\langle \tilde{T}_G^* \tilde{T}_G \mu, k \rangle = \langle \tilde{T}_G^* \mu, h \rangle = \langle \mu, k \rangle$ on $C_{3v}$, for all $\mu, k$, i.e., $\tilde{T}_G^*$ is also a right inverse. Finally, we choose $h = \tilde{T}_G^* k$ in (4.7) and employ (4.9) to deduce

$$\langle \delta U(\lambda, T_G u), k \rangle = \langle \delta U(\lambda, u), \tilde{T}_G^* k \rangle = \langle \tilde{T}_G \delta U(\lambda, u), k \rangle,$$

for all $G \in C_{3v}$ and for all admissible $k$. This completes the proof. □

Appendix 2

Here we discuss the $C_{2v}$— symmetry of the transcritical bifurcation, depicted in Fig. 13, associated with irrep $\gamma^{(5)}$. As noted in Sect. 3, (2.33) and (3.12) reveal that $\gamma^{(5)}$ is associated (faithfully) with $D_3$— symmetry on $\mathbb{R}^2$, but with each element appearing twice. Hence, the maximal isotropy subgroup of the fixed-point space $\text{span}\{i_1\}$ is actually $\Sigma = \{\gamma^{(5)}_I, \gamma^{(5)}_E, \gamma^{(5)}_I, \gamma^{(5)}_E\}$, which is a representation of $D_2 := \{\gamma^{(6)}_I, \gamma^{(6)}_E, \gamma^{(6)}_R, \gamma^{(6)}_{ER}\} \subset D_6$. Accordingly, we can build a projection operator on configuration space with the symmetry of $\Sigma$ via

$$P_\Sigma = \frac{1}{4}[T_I + T_E + T_{R_\pi} + T_{ER_\pi}],$$

where we use the $[1]_{11}$ entries of the matrices comprising $\Sigma$ for weights (McWeeny 2002), each of which equals 1 in this case. The operators $T_G$ are defined via the
generators (3.8). Then $P_\Sigma u \in \mathcal{X}_\Sigma$, for any configuration $u \in \mathcal{X}_\Sigma$, cf. (2.31), (3.2). We now observe that

$$T_E P_\Sigma = T_E [T_I + T_E + T_{R_\pi} + T_{ER_\pi}] / 4 = [T_E + T_I + T_{ER_\pi} + T_{R_\pi}] / 4 = P_\Sigma,$$

$$T_{ER_\pi} P_\Sigma = T_{ER_\pi} [T_I + T_E + T_{R_\pi} + T_{ER_\pi}] / 4 = [T_{ER_\pi} + T_{R_\pi} + T_E + T_I] / 4 = P_\Sigma.$$

(5.1)

Above we have used the fact that $T_GT_H = T_{GH}$ for all $G, H \in C_{6v} \cong D_6$. Finally, for any $v = P_\Sigma u \in \mathcal{X}_\Sigma$, (5.1) implies $T_{R_\pi} v = v, T_E v = v$, and $T_{ER_\pi} v = v$, i.e., the configuration possesses $C_{2v}$ symmetry.
