Process tomography, the experimental characterization of physical processes, is a central task in science and engineering. Here we investigate the axiomatic requirements that guarantee the in-principle feasibility of process tomography in general physical theories. Specifically, we explore the requirement that process tomography should be achievable with a finite number of auxiliary systems. We show that this requirement is satisfied in every theory equipped with universal extensions, that is, correlated states from which all other correlations can be generated locally with non-zero probability. We show that universal extensions exist in two cases: (1) theories permitting conclusive state teleportation, and (2) theories satisfying three properties of Causality, Pure Product States, and Purification. In case (2), the existence of universal extensions follows from a symmetry property of Purification, whereby all pure bipartite states with the same marginal on one system are locally interconvertible. Crucially, our results hold even in theories that do not satisfy Local Tomography, the property that the state of any composite system can be identified from the correlations of local measurements. Summarizing, the existence of universal extensions, without any additional requirement of Local Tomography, is a sufficient guarantee for the characterizability of physical processes using a finite number of auxiliary systems.

I. INTRODUCTION

The experimental characterization of physical processes is an important component of the scientific method. Such a characterization, known as process tomography, is widely adopted in classical \[1\] and quantum technologies \[2–14\]. In general, one can regard the in-principle feasibility of process tomography as a requirement for the construction of new physical theories: arguably, a sensible physical theory should describe processes that—at least in principle—can be characterized experimentally.

Operational axioms inspired by process tomography were first proposed by D’Ariano in a sequence of works \[15–18\] where they featured as potential candidates for an axiomatization of quantum theory. In this paper, we will explore the conditions that guarantee the feasibility of process tomography in general physical theories, independently of the quantum axiomatization problem. Specifically, our goal will be to identify physical conditions that guarantee the achievability of process tomography using a finite number of auxiliary systems/a finite number of input states.

To understand the role of auxiliary systems in process tomography, it is useful to consider first a popular approach known as standard process tomography \[2,3\], where no auxiliary system is used. Standard process tomography aims at characterizing processes by letting them act on a set of input states and by analyzing the output with a set of measurements, as in the following schematic

\[
\begin{array}{c}
\rho^{(i)} \quad \text{A} \\
\begin{array}{c}
\text{P} \\
\text{B}
\end{array} \\
m^{(j)} \quad \text{M}
\end{array}
\]

(1)

Here, an unknown process \( \mathcal{P} \) (with input system A and output system B) is tested on a set of fiducial states \( \{\rho^{(i)}\}_{i=1}^N \) with a set of fiducial measurements \( \{m^{(j)}\}_{j=1}^M \). We use the boldface notation \( m^{(j)} \) to indicate that the \( j \)-th measurement has multiple outcomes, labelled by some index that is not written down explicitly. By choosing a complete set of fiducial states and measurements, one can then identify the action of the process \( \mathcal{P} \) on its input system—that is, one can uniquely determine the function \( f_{\mathcal{P}} \) that maps a generic input state of system A into the corresponding output state of system B.

In classical and quantum physics, standard process tomography is sufficient to completely characterize physical processes: by determining the function \( f_{\mathcal{P}} \), one can identify the action of the process \( \mathcal{P} \) in every possible experiment, even including experiments where the process \( \mathcal{P} \) acts locally on a part of a composite system. For example, this includes experiments of the form

\[
\begin{array}{c}
\Psi \\
\begin{array}{c}
\text{C} \\
\text{A} \\
\text{P} \\
\text{B} \\
\text{M}
\end{array}
\end{array}
\]

(2)

where \( \mathcal{P} \) is applied locally on a joint state \( \Psi \) of systems A and system C, and a joint measurement \( \mathcal{M} \) is performed on systems B and C.
In classical and quantum theory, the outcome probabilities of all experiments of type (1) are uniquely determined by the outcome probabilities of experiments of type (2). The origin of this favourable situation is a property, known as Local Tomography, whereby the states of every composite system can be uniquely identified by performing local measurements on the components. In quantum foundations, Local Tomography has often been taken as an axiom for the characterization of standard quantum theory (on complex Hilbert spaces) and as a principle for the construction of new physical theories. In locally tomographic theories, the action of a process on its input system uniquely determines the action of the process on every composite system. As a result, standard process tomography provides a complete characterization of physical processes.

The situation is radically different when Local Tomography does not hold. A simple counterexample arises in real-vector-space quantum theory, a variant of standard quantum theory that violates Local Tomography and deviates from standard quantum theory in a number of operational tasks. In real-vector-space quantum theory, one can find explicit examples of processes that have the same input-output function, and yet act in completely different ways on composite systems.

When Local Tomography fails, the only way to unambiguously identify a process is to test its action on composite systems, using an approach known as ancilla-assisted process tomography. This approach consists in performing experiments of the type of Eq. (2). Now, the crucial question is: which auxiliary systems C have to be taken into account? In the worst case, the answer could be “all possible systems”: the characterization of an unknown physical process may require experiments performed, as it were, on the whole universe. It seems natural to demand, as a basic principle, that physical theories should be free from this pathology. In a sensible physical theory, it should be in principle possible to identify any given process up to any desired level of accuracy using a finite number of experimental settings. This means: testing the process with a finite number of auxiliary systems, preparing a finite number of states, and performing a finite number of measurements, each with a finite number of outcomes.

In this paper, we will focus on the requirements of a finite number of auxiliary systems/finite number of inputs states, and we will consider the case of process tomography with ideally perfect accuracy. We will require that, at least in principle, physical processes can be completely characterized by probing their action with a finite number of auxiliary systems. Note that, in turn, every finite set of auxiliary systems \( \{C_i\}_{i=1}^k \) can be replaced without loss of generality by a single auxiliary system R, for example by merging all the systems of the finite set into a composite system. This observation motivates the following requirement:

**Principle 1 (Dynamically Faithful Systems)** For every pair of systems A and B, there exists an auxiliary system R such that all processes with input A and output B can be completely characterized by their action on the states of the composite system A \( \otimes \) R.

We will also consider a slightly stronger requirement, inspired by D’Ariano’s early axiomatization works. The requirement stipulates the achievability of process tomography with a single state of a suitable composite system.

**Principle 2 (Dynamically Faithful States)** For every pair of systems A and B, there exists an auxiliary system R such that all processes with input A and output B can be completely characterized by their action on a single state of the composite system A \( \otimes \) R.

Dynamically Faithful Systems/Dynamically Faithful States are strictly weaker requirements than Local Tomography. For example, real-vector-space quantum theory violates Local Tomography but satisfies Dynamically Faithful States (and therefore Dynamically Faithful Systems): every real-vector-space process with input A can be uniquely characterized by its action on an entangled state of the composite system A \( \otimes A \). It is also worth noting that Dynamically Faithful Systems/Dynamically Faithful States do not imply finite dimensionality: for example, all the processes on a quantum system with separable Hilbert space can be characterized by preparing a single bipartite state. Nevertheless, in this paper we will be mostly concerned with finite dimensional systems for simplicity of presentation.

The core result of the paper is a mathematical characterization of the theories satisfying Dynamically Faithful States. The characterization is valid for a broad class of physical theories—so broad that, in fact, it even includes non-causal theories where the choices of experiments performed in the future can affect the outcome probabilities of experiments performed in the past. After providing the mathematical characterization, we identify physical conditions that guarantee Dynamically Faithful States. Specifically, we show that Dynamically Faithful States holds in all theories where all correlations of a given physical system with its environment can be probabilistically generated by local operations on a single “universally correlated state.” We call this property Universal Extension. Two important classes of theories satisfying Universal Extension are (1) the theories allowing for conclusive teleportation, and (2) the theories satisfying three requirements of Causality, Pure Product States, and Purification. Informally, Causality is the requirement that the outcome probabilities of present experiments are independent on the choice of future experiments. Pure Product States is the requirement that if the parts of a composite system are in pure states, then the whole composite system is in a pure state. Purification is the requirement that every
mixed state can be extended to a pure state, and that such extension is unique up to local symmetry transformations \[24, 26, 28, 43, 49, 51, 52\]. Remarkably, the symmetry property of purifications guarantees that every purification is a universal extension, and therefore every theory with purification has Dynamically Faithful States. Our main results can be summarized by the following logical implications:

1. Conclusive Teleportation \(\Rightarrow\) Universal Extension
2. Causality, Pure Product States, and Purification \(\Rightarrow\) Universal Extension
3. Universal Extension \(\Rightarrow\) Dynamically Faithful States \(\Rightarrow\) Dynamically Faithful Systems.

The overall conclusion of our results is that Universal Extension guarantees the in-principle characterizability of physical processes, without invoking any assumption of Local Tomography.

II. MATERIALS AND METHODS

In this section we briefly introduce the framework and the notation used in the paper.

A. Operational-probabilistic theories

A major trend in quantum foundations is the study of information-processing tasks in a broad class of general probabilistic theories, which include quantum theory as a special case \[21–24, 27, 28, 43, 49, 53–56\]. A convenient approach to general probabilistic theories is provided by the framework of operational-probabilistic theories (OPTs) \[24, 27, 28, 43, 49, 54–58\]. The framework consists of two distinct conceptual ingredients: an operational structure, describing circuits that produce outcomes, and a probabilistic structure, which assigns probabilities to the outcomes. The operational structure is inspired by the approach of categorical quantum mechanics \[45, 59–62\] (see also \[50\] for a recent presentation), and follows it rather closely, although there are a few relevant differences in the way classical outcomes are treated \[57, 58\].

The OPT framework describes a set of experiments that can be performed on a given set of systems with a given set of physical processes. The framework is based on a primitive notion of composition, whereby every pair of physical systems \(A\) and \(B\) can be combined into a composite system \(A \otimes B\). The set of all physical systems is closed under composition, and will be denoted by \(\text{Sys}\). Physical processes can be combined in sequence or in parallel to build circuits, such as

\[
\begin{align*}
\rho & \quad \downarrow\ A \quad \downarrow\ A' \quad \downarrow\ A'' \quad \downarrow\ B' \quad \downarrow\ B. \\
\text{B} & \quad \uparrow\ A \quad \uparrow\ A' \quad \uparrow\ A'' \quad \uparrow\ B' \quad \uparrow\ B. \\
\end{align*}
\]

In this example, \(A, A', A'', B, B'\) are systems, \(\rho\) is a state of the composite system \(A \otimes B\), \(A, A'\) and \(B\) are transformations (a.k.a. processes), \(a\) and \(b\) are measurements. We use boldface fonts \(a\) and \(b\) for measurements in order to indicate that they generally have multiple outcomes. When necessary, we will explicitly write \(a = (a_x)_{x \in X}\) and \(b = (b_y)_{y \in Y}\), where \(x\) and \(y\) are measurement outcomes, and \(X\) and \(Y\) are the sets of possible outcomes of the two experiments. Here \(a_x\) and \(b_y\) play the same role as the linear operators associated to the outcomes of quantum measurements. Following a traditional terminology dating back to Ludwig \[63\], we will call them effects.

Among the list of valid physical systems, every OPT includes a trivial system, denoted by \(I\) and corresponding to the degrees of freedom ignored by theory. States (resp. effects) are transformations with the trivial system as input (resp. output).

Transformations from the trivial system to itself are called scalars. Physically, they are associated to circuits with no external wires, like the circuit in Eq. (3). In the OPT framework, scalars are typically identified with numerical probabilities, valued in the interval \([0, 1] \subset \mathbb{R}\). More generally, other identifications are also possible, including signed probabilities or possibilities, as shown in the work of Gogioso and Scandolo \[58\]. In the following, we will not make any assumption on the nature of the scalars, although we will often call them “probabilities” to facilitate the connection to the existing literature in quantum foundations.

For generic systems \(A\) and \(B\), we denote by

- \(\text{Transf}(A \rightarrow B)\) the set of transformations from \(A\) to \(B\), also called transformations of type \(A \rightarrow B\)
- \(\text{St}(A) := \text{Transf}(I \rightarrow A)\) the set of states of system \(A\),
• \( \mathbf{B} \circ \mathbf{A} \) (or \( \mathbf{B} \mathbf{A} \), for short) the sequential composition of two transformations \( \mathbf{A} \) and \( \mathbf{B} \), with the input of \( \mathbf{B} \) matching the output of \( \mathbf{A} \),
• \( \mathbf{A} \otimes \mathbf{B} \) the parallel composition of the transformations \( \mathbf{A} \) and \( \mathbf{B} \).
• \( \mathcal{I}_A \) the identity transformation on system \( A \)
• \( 1 := \mathcal{I}_I \) the identity transformation on the trivial system.

**Definition 1** We say that two transformations \( \mathcal{P} \) and \( \mathcal{P}' \) are operationally indistinguishable \([24]\) if they give rise to the same probabilities in all possible experiments, namely

\[
\vcenter{\hbox{{$\begin{array}{c}{\mathcal{P}} \\
A \quad {\mathcal{P}}' \\
B \\

\end{array}$}} = \vcenter{\hbox{{$\begin{array}{c}{\mathcal{P}} \\
A \quad {\mathcal{P}}' \\
B \\

\end{array}$}}} \quad \forall \mathcal{C} \in \text{Sys}
\forall \mathcal{T} \in \text{St}(A \otimes C)
\forall \mathcal{E} \in \text{Eff}(B \otimes C)}
\]

(4)

In this paper we will focus our attention on quotient theories \([33, 49]\) where physical transformations that are operationally indistinguishable are identified: in other words, we will assume that condition (4) implies the equality

\[
\vcenter{\hbox{{$\begin{array}{c}{\mathcal{P}} \\
A \quad {\mathcal{P}}' \\
B \\

\end{array}$}} = \vcenter{\hbox{{$\begin{array}{c}{\mathcal{P}} \\
A \quad {\mathcal{P}}' \\
B \\

\end{array}$}}} .}
\]

(5)

When the scalars are positive real numbers, the set of transformations \( \text{Transf}(A \to B) \) in the quotient theory can be regarded as elements of an ordered vector space \([24, 43, 49, 64]\).

Every transformation takes place in a test, that is, a non-deterministic process that generates an outcome out of a set of possible outcomes. Mathematically, a test of type \( A \to B \), with outcomes in \( X \), is a list of transformations of type \( A \to B \) indexed by elements of the outcome set \( X \). We denote such a list by \( \mathcal{T} = (T_x)_{x \in X} \), with \( T_x \in \text{Transf}(A \to B) \) for every \( x \in X \).

Tests of type \( I \to A \) are called preparation tests, or sources. A preparation test \( \rho = (\rho_x)_{x \in X} \) describes the non-deterministic preparation \([67]\) of the state \( \rho_x \), heralded by an outcome \( x \in X \). Tests of type \( A \to I \) are called measurements. A measurement \( \mathcal{A} = (a_y)_{y \in Y} \) is a collection of effects labelled by measurement outcomes.

A transformation is deterministic if it is part of a test with a single outcome. By definition, deterministic transformations can be performed deterministically by setting up the corresponding test. We use the notations

• \( \text{DetTransf}(A \to B) \) for the set of deterministic transformations of type \( A \to B \),
• \( \text{DetSt}(A) \) for the set of deterministic states of system \( A \),
• \( \text{DetEff}(A) \) for the deterministic effects of system \( A \).

For the trivial system \( I \), we assume that there exists only one deterministic transformation of type \( I \to I \), namely the identity transformation \( 1 \). This assumption was introduced by Coecke in Ref. \([60]\), motivated by the interpretation of the scalars as “probabilities,” which suggests that there should be only one deterministic scalar, corresponding to the notion of certainty.

We assume that the set of tests is closed under coarse-graining, the operation of joining together two or more outcomes. Given a test \( \mathcal{T} = (T_x)_{x \in X} \) and a partition of the outcome set \( X \) into disjoint subsets \( (X_y)_{y \in Y} \), we define the coarse-grained test \( \mathcal{S} = (S_y)_{y \in Y} \) as the test with transformations

\[
S_y := \sum_{x \in X_y} T_x .
\]

(6)

At this level, the symbol of sum is just a notation for the operation of coarse-graining: the only mathematical requirements on the coarse-graining operation is that it distributes over parallel and sequential composition, namely

\[
\mathcal{A} \otimes \left( \sum_{x \in X_y} T_x \right) = \sum_{x \in X_y} \left( \mathcal{A} \otimes T_x \right) \quad \text{and} \quad \left( \sum_{x \in X_y} T_x \right) \otimes \mathcal{A} = \sum_{x \in X_y} \left( T_x \otimes \mathcal{A} \right) ,
\]

(7)

for every transformation \( \mathcal{A} \),

\[
\mathcal{B} \circ \left( \sum_{x \in X_y} T_x \right) = \sum_{x \in X_y} \left( \mathcal{B} \circ T_x \right) ,
\]

(8)
for every transformation $B$ with input matching the output of $T$, and
\[
\left( \sum_{x \in \mathcal{X}} T_x \right) \circ C = \sum_{x \in \mathcal{X}} (T_x \circ C),
\]
(9)

for every transformation $C$ with output matching the input of $T$. Closely related notions of coarse-graining were proposed in the works of Tull \[57\], Gogioso and Scandolo \[58\], where Eqs. (7-9) were assumed together with a few additional requirements.

Since there is only one deterministic transformation of type $I \to I$ (the scalar 1), every test $p = (p_x)_{x \in \mathcal{X}}$ of type $I \to I$ satisfies the normalization condition
\[
\sum_{x \in \mathcal{X}} p_x = 1.
\]
(10)

This condition is the analogue of the normalization of a probability distribution. For this reason, in the following we will call the tests of type $I \to I$ “probability distributions,” even though in general the scalars may not be real numbers in the interval $[0, 1]$.

When the scalars are real numbers, the sum notation used above is consistent with the notion of sum in the ordered vector space containing the physical transformations in the quotient theory \[24, 43, 49, 64\] (cf. Definition 3 and comments below it).

B. Framework assumptions

In this paper we will make four basic assumptions that are shared by most probabilistic theories in the literature. We spell out the assumptions explicitly because they will play a significant role in our results, and it is convenient to keep track of which assumption is used in which result. For example, we will write “Lemma 1 (A1,A2, A3)” to state that that Lemma 1 follows from assumptions 1, 2, and 3.

Our first assumption is that all non-deterministic tests arise from deterministic processes followed by measurements. This assumption is compatible with the idea that the outcomes can be read-out from some physical system, like the display of a device, and that such system is also described by the theory. The readout process is then realized as a deterministic transformation, followed by a measurement on the display:

Assumption 1 (Displays \[49\]) Every test arises from a deterministic transformation followed by a measurement on one of the output systems.

Formally, Assumption 1 is that every test $T = (T_x)_{x \in \mathcal{X}}$ of type $A \to B$ can be realized as
\[
A \xrightarrow{T_x} B \quad = \quad A \xrightarrow{D} B \xrightarrow{C} F_x \quad \forall x \in \mathcal{X}.
\]
(11)

for some system $C$, some deterministic transformation $D$, and some measurement $c = (c_x)_{x \in \mathcal{X}}$.

Our second assumption is that the set of systems described by the theory includes some “coin”, that is, some physical system that generates a pair of random outcomes. In the familiar setting where probabilities are numbers in the interval $[0, 1]$, the assumption is that there exists some two-outcome experiment whose outcome probabilities are both non-zero. In the general case, an analogue of non-zero probability is a cancellative scalar: a scalar $s$ is cancellative if the condition $s p = s p'$ implies $p = p'$ for every pair of scalars $p$ and $p'$.

Assumption 2 (Coins) There exist two-outcome experiments whose outcome probabilities are both cancellative.

We stress that we do not assume the existence of coins with arbitrary biases: even if the scalars are real numbers, we do not assume that they are the whole interval $[0, 1]$.

An important property of cancellative scalars is that they cancel out in equations involving arbitrary transformations:

Lemma 1 For a cancellative scalar $s$, the condition $s \mathcal{P} = s \mathcal{P}'$ implies $\mathcal{P} = \mathcal{P}'$, for every pair of processes $\mathcal{P}$ and $\mathcal{P}'$ of the same type.
the notion of complete state will be discussed in Subsection III C. Generally not satisfied by classical and quantum theory infinite dimensions. An infinite-dimensional generalization of deterministic states is not convex. For example, it is satisfied in Spekkens’ toy theory \[68, 69\], where some convex combinations are forbidden but nevertheless the set of deterministic states contains a complete state. However, Assumption 4 is generally not satisfied by classical and quantum theory infinite dimensions. An infinite-dimensional generalization of the notion of complete state will be discussed in Subsection III C.

**Proof.** Given two processes \( P \) and \( P' \) of type \( A \to B \), the condition \( s P = s P' \) implies

\[
\Gamma_{\mathcal{A}} P \otimes x = s \quad \Rightarrow \quad \Gamma_{\mathcal{A}} P' \otimes x
\]

which in turn implies

\[
\Gamma_{\mathcal{A}} P \otimes x = \Gamma_{\mathcal{A}} P' \otimes x
\]

because \( s \) is cancellative. Hence, the processes \( P \) and \( P' \) are operationally indistinguishable, in the sense of Definition 4. Since we are dealing with a quotient theory, this condition implies \( P = P' \).

Our third assumption is that it is possible to perform randomized tests. Informally, a randomized test is a test where one tosses a coin and performs a test depending on the outcome of the coin toss. Here we give the formal definition for the randomization of two tests (the extension to more than two tests is straightforward):

**Definition 2** Let \( T \) and \( S \) be two tests of type \( A \to B \), with outcomes in \( X \) and \( Y \), respectively, and let \( (p_0, p_1) \) be a probability distribution allowed by the theory (i.e., a test of type \( I \to I \)). The randomization of \( T \) and \( S \) with probabilities \( (p_0, p_1) \) is a test \( R \) of type \( A \to B \), with outcomes in the disjoint union \( Z = X \sqcup Y \), in which all elements of \( X \) are regarded as distinct from all elements of \( Y \). The test \( R \) is defined as

\[
R_z = \begin{cases} 
  p_0 T_z & \text{if } z \in X \\
  p_1 S_z & \text{if } z \in Y
\end{cases}
\]

(14)

Our third assumption is that all randomizations are valid tests:

**Assumption 3 (Randomizations)** The set of tests is closed under randomizations.

The Randomizations Assumption, together with the possibility of coarse graining, guarantees the existence of random mixtures, defined as follows:

**Definition 3** Let \( \sigma \) and \( \tau \) be two deterministic states of system \( A \) and let \( (p_0, p_1) \) be a probability distribution allowed by the theory. The mixture of \( \sigma \) and \( \tau \) with probabilities \( (p_0, p_1) \) is the deterministic state \( \rho \) defined by

\[
\rho := p_0 \sigma + p_1 \tau
\]

(15)

The notion of mixture introduces a pre-order relation on the set of deterministic states:

**Definition 4** Let \( \rho \) and \( \sigma \) be two deterministic states of system \( A \). We say that \( \rho \) contains \( \sigma \), denoted as \( \rho \supseteq \sigma \), if \( \rho = p_0 \sigma + p_1 \tau \), where \( (p_0, p_1) \) is a probability distribution allowed by the theory, \( p_0 \) is a cancellative scalar, and \( \tau \) is a deterministic state.

Note that the relation \( \supseteq \) is transitive: if \( \rho \supseteq \sigma \) and \( \sigma \supseteq \tau \), then \( \rho \supseteq \tau \).

Our final assumption is about the existence of complete states, defined as follows:

**Definition 5** A deterministic state \( \rho \in \text{DetSt}(A) \) is complete if \( \rho \supseteq \sigma \) for every deterministic state \( \sigma \in \text{DetSt}(A) \).

The assumption is:

**Assumption 4 (Complete States)** For every system, there exists at least one complete state.
C. Local Tomography

In this section we review the property of Local Tomography. The scope of this review is to clarify, by contrast, what it means to characterize physical processes in theories where Local Tomography does not hold.

The Local Tomography has been formulated in several forms and under different names \[16, 19–25\]. A simple formulation is the following \[26\].

**Definition 6 (Local Tomography)** A physical theory satisfies Local Tomography if the state of every composite system is uniquely determined by the joint statistics of local measurements on the components.

Mathematically, Local Tomography states that, for every pair of systems \(A\) and \(B\), and for every pair of states of the composite system \(A \otimes B\), say \(\rho\) and \(\rho'\), the condition

\[
\rho_{AB} = \rho'_{AB}
\]

implies the equality

\[
\rho_{A} = \rho'_{A}.
\]

D. Standard process tomography

Local Tomography has an important implication for the task of characterizing physical processes: in every locally tomographic theory, the action of a process on its input system determines the action of the process on all possible composite systems. Explicitly, one has the following

**Proposition 1 (Lemma 14 of \[24\])** Suppose that the theory satisfies Local Tomography. Then, for every pair of systems \(A\) and \(B\) and for every pair of processes \(P\) and \(P'\) of type \(A \rightarrow B\), the condition

\[
(\rho P B) = (\rho' P' B) \quad \forall \rho \in \text{St}(A)
\]

implies the equality

\[
(\Gamma C) = (\Gamma C) \quad \forall \Gamma \in \text{St}(A \otimes C),
\]

or equivalently, the equality

\[
A P B = A P' B.
\]

When system \(A\) is finite dimensional, Proposition 1 guarantees that one can characterize an arbitrary process of type \(A \rightarrow B\) by applying it to a fiducial set of input states of system \(A\), and by characterizing the output states of system \(B\) with a fiducial set of measurements. This result is the conceptual foundation underpinning standard process tomography \[2, 3\].

Interestingly, a converse of Proposition 1 also holds, under the assumption that the all states of all composite systems can be probabilistically generated by acting locally on one part of a fixed bipartite state. This point is discussed in Appendix A.

E. The counterexample of real-vector-space quantum theory

When Local Tomography does not hold, standard process tomography may not work. A simple example can be found in real-vector-space quantum theory \[36\], a variant of standard quantum theory that violates Local Tomography \[19, 20\] and deviates from standard quantum theory in a number of operational tasks \[20, 24, 37–42\]. The example,
introduced in [43], involves two processes, $\mathcal{P}$ and $\mathcal{P}'$, acting on a “rebit”, that is, a two-dimensional quantum system associated to the vector space $\mathbb{R}^2$. Mathematically, the two processes are defined by the linear maps

$$\mathcal{P}(M) = \frac{1}{2} (M + YMY)$$

$$\mathcal{P}'(M) = \frac{1}{2} (XMX + ZMZ),$$

(21)

where $M$ is a generic $2 \times 2$ matrix and $X := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, $Y := \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$, $Z := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ are the three Pauli matrices. Now, consider the action of the two processes on a single-rebit, whose possible states are described by density matrices with real entries. Writing a generic real-valued density matrix $\rho$ in the Bloch form

$$\rho = \frac{I + \cos \theta X + \sin \theta X^2}{2}, \quad \theta \in [0, 2\pi)$$

(22)

we can easily obtain the relation

$$\mathcal{P}(\rho) = \frac{I}{2} = \mathcal{P}'(\rho),$$

(23)

meaning that the two processes $\mathcal{P}$ and $\mathcal{P}'$ act in the same way on every single-rebit input state.

On the other hand, the processes $\mathcal{P}$ and $\mathcal{P}'$ are clearly different. The difference can be detected by applying the processes on a maximally entangled state of two rebits: for example, using the notation

$$|\Phi^+\rangle := |0\rangle \otimes |0\rangle + |1\rangle \otimes |1\rangle$$

$$|\Phi^-\rangle := |0\rangle \otimes |0\rangle - |1\rangle \otimes |1\rangle$$

$$|\Psi^+\rangle := |0\rangle \otimes |1\rangle + |1\rangle \otimes |0\rangle$$

$$|\Psi^+\rangle := |0\rangle \otimes |1\rangle - |1\rangle \otimes |0\rangle$$

one has

$$\langle P \otimes I |(\Phi^+)\langle\Phi^+| = \frac{1}{2} |\Phi^+\rangle \langle\Phi^+| + |\Psi^-\rangle \langle\Psi^-|$$

$$\langle P \otimes I |(\Phi^+)\langle\Phi^+| = \frac{1}{2} |\Psi^+\rangle \langle\Psi^+| + |\Phi^-\rangle \langle\Phi^-|. $$

(25)

Note that the output states are not only different, but also orthogonal, meaning that a joint measurement on the two rebits can tell the two states apart without any error. The two states in the r.h.s. of Eq. (25) were first studied by Wootters [20] as an example of bipartite states that perfectly distinguishable by global measurements, and yet completely indistinguishable by local measurements in real-vector-space quantum theory.

Summarizing, standard process tomography does not work in real-vector-space quantum theory: in order to unambiguously characterize an unknown process on real-vector space quantum states, it is mandatory to test it on composite systems.

### III. RESULTS

#### A. Mathematical Characterization of Dynamically Faithful Systems

In the lack of Local Tomography, process tomography requires experiments on composite systems. Now, the key question is: which composites have to be tested? In principle, the answer could be “all”: a process with input system $A$ may have to be tested on every composite system $A \otimes C$ for every possible auxiliary system $C$. Loosely speaking, the only way to completely characterize a process would be to make experiments on “the whole universe”.

This situation does not arise in real-vector-space quantum theory: there, a complete process tomography can be achieved by preparing a single input state of a single composite system. Specifically, process tomography can be
achieved by preparing two identical copies of the input system in a maximally entangled state and by letting the process act on one copy \[71\]. In other words, real-vector-space quantum theory satisfies the principle of Dynamically Faithful States (Principle 2 in the introduction).

In the rest of the paper we will investigate the conditions that guarantee the validity of Dynamically Faithful States in general physical theories.

B. Four levels of process tomography

The goal of tomography is to characterize the action of an unknown process on all possible inputs. Nevertheless, it is also useful to first consider intermediate tasks where the goal is to characterize the process on a subset of inputs. In this Section we define three such tasks, listed in order of increasing strength. All together, these three tasks and the task of full process tomography define four levels of characterization of physical processes.

1. Equality on a source

Consider the situation where a source prepares system A in a non-deterministic fashion. Such a source can be described by a preparation test \( \rho = (\rho_x)_{x \in X} \), where the preparation of the state \( \rho_x \) is heralded by the outcome \( x \). The states in the source are then used as inputs:

\[
\text{Definition 7} \quad \text{We say that two processes } P \text{ and } P', \text{ of type } A \rightarrow B, \text{ are equal on the source } (\rho_x)_{x \in X} \text{ if one has }
\]

\[
\rho_x \xrightarrow{P} A \quad \rho_x \xrightarrow{P'} B \quad \forall x \in X .
\] (26)

When this is the case, we write \( P \sim_\rho P' \).

It is easy to see that \( \sim_\rho \) is an equivalence relation. The equivalence relation \( \sim_\rho \) defines a weak notion of process tomography, where the goal is just to identify the action of processes on the fixed set of states \( \{\rho_x, x \in X\} \).

2. Equality upon input of a state

We now consider a stronger notion of process tomography. Instead of characterizing a process on a single source, one can try to characterize the process on all sources with the same average state. The average state of a source \( \rho = (\rho_x)_{x \in X} \) is the deterministic state

\[
\rho := \sum_{x \in X} \rho_x ,
\] (27)

obtained by coarse-graining over all possible outcomes.

\[
\text{Definition 8} \quad \text{We say that two processes } P \text{ and } P', \text{ of type } A \rightarrow B, \text{ are equal upon input of } \rho \text{ if they are equal on every source } \rho = (\rho_x)_{x \in X} \text{ with average state equal to } \rho. \text{ When this is the case, we write } P =_\rho P'.
\]

The condition \( P =_\rho P' \) is equivalent to the condition

\[
\sigma \xrightarrow{P} A \quad \sigma \xrightarrow{P'} B \quad \forall \sigma : \sigma \subseteq \rho ,
\] (28)

where the notation \( \sigma \subseteq \rho \) means that \( \sigma \) is contained in \( \rho \), that is, that there exists a source \( \rho = (\rho_0, \rho_1) \) such that \( \rho_0 + \rho_1 = \rho \) and \( \rho_0 = p_0 \sigma \) for some cancellative scalar \( p_0 \) [73].

In quantum information, the notion of equality upon input of \( \rho \) was introduced in [72]. Its extension to general probabilistic theories was discussed in [24, 27, 28].

It is easy to check that equality upon input of \( \rho \) is an equivalence relation. Note that, by definition, identifying a process upon input of \( \rho \) is more demanding than just identifying it on a specific source \( (\rho_x)_{x \in X} \) with average state \( \rho \).
3. Equality on the extensions of a state

All notions of process tomography considered so far focussed on the action of a process on its input system alone. To identify the process, however, one also needs to characterize its local action on composite systems.

Definition 9 Let \( \rho \in \text{DetSt}(A) \) be a deterministic state of system \( A \). An extension of \( \rho \) on system \( E \) is a deterministic state \( \Gamma \in \text{DetSt}(A \otimes E) \) satisfying the relation

\[
\Gamma_{A} = \rho_{A} \quad \text{for some deterministic effect } e \in \text{DetEff}(E).
\]

We denote by \( \text{Ext}(\rho, E) \) the set of all extensions of \( \rho \) on system \( E \).

Our third level of process tomography is to identify the action of a process on all the extensions of a given state.

Definition 10 We say that two processes \( \mathcal{P} \) and \( \mathcal{P}' \) are equal on the extensions of \( \rho \) if one has

\[
\Gamma_{A} \mathcal{P}_{B} \Gamma_{E} = \Gamma_{A} \mathcal{P}'_{B} \Gamma_{E}
\]

for every possible system \( E \) and for every possible extension \( \Gamma \in \text{Ext}(\rho, E) \). In this case, we write \( \mathcal{P} \equiv_{\rho} \mathcal{P}' \).

In general, equality on all the extensions of \( \rho \) implies equality upon input of \( \rho \). This is because all sources with average state \( \rho \) can be viewed as extensions of \( \rho \) involving an environment serving as a “display”. Explicitly, we have the following:

Lemma 2 (A1) Let \( \rho \in \text{DetSt}(A) \) be a deterministic state of system \( A \), and let \( \rho = (\rho_x)_{x \in X} \) be an arbitrary source with average state \( \rho \). Then, there exists an extension \( \Gamma \in \text{Ext}(\rho, E) \), for suitable system \( E \), such that, for every pair of processes \( \mathcal{P} \) and \( \mathcal{P}' \) of type \( A \rightarrow B \), with arbitrary system \( B \), the condition

\[
\Gamma_{A} \mathcal{P}_{B} \Gamma_{E} = \Gamma_{A} \mathcal{P}'_{B} \Gamma_{E}
\]

implies the condition

\[
\rho_x A \mathcal{P} B = \rho_x A \mathcal{P}' B \quad \forall x \in X.
\]

The proof is provided in Appendix B. An immediate consequence is that equality on all the extensions of \( \rho \) implies equality upon input of \( \rho \):

Corollary 1 (A1) Let \( \rho \in \text{DetSt}(A) \) be a deterministic state of system \( A \). Then, for every pair of processes \( \mathcal{P} \) and \( \mathcal{P}' \) of type \( A \rightarrow B \), with arbitrary system \( B \), one has the implication

\[
\mathcal{P} \equiv_{\rho} \mathcal{P}' \quad \Rightarrow \quad \mathcal{P} =_{\rho} \mathcal{P}'.
\]

\( \mathcal{P} =_{\rho} \mathcal{P}' \)

In Appendix B we also show that the relations \( =_{\rho} \) and \( =_{\rho} \) coincide in the special case of theories satisfying Local Tomography and Causality, the principle that the outcome probabilities of present experiments are independent on the choice of future experiments.

4. Equality on all states

The ultimate goal of process tomography is to identify the action of an unknown process on all possible states. Using the results collected so far, the condition for perfect identification can be expressed as follows:

Lemma 3 (A1) Let \( \mathcal{P} \) and \( \mathcal{P}' \) be two processes of type \( A \rightarrow B \). Then, one has the condition

\[
\mathcal{P} = \mathcal{P}' \quad \Leftrightarrow \quad \mathcal{P} =_{\rho} \mathcal{P}', \quad \forall \rho \in \text{DetSt}(A).
\]

The proof is provided in Appendix C. Summarizing, two processes of type \( A \rightarrow B \) are equal if and only if they coincide on all the extensions of all deterministic states of system \( A \). In Subsection III E we will show that, in fact, the extensions of a single state are enough.
C. Tomographic ordering and dynamically faithful states

A natural notion in the context of process tomography is the notion of tomographic ordering:

**Definition 11** Let \( \Phi \in \text{St}(A \otimes R) \) and \( \Psi \in \text{St}(A \otimes E) \) be two (possibly non-deterministic) states. We say that \( \Phi \) is tomographically more powerful than \( \Psi \) for processes of type \( A \to B \), if, for every pair of processes \( P \) and \( P' \) of type \( A \to B \), the condition

\[
\Phi \frac{A}{R} P B = \Phi \frac{A}{R} P' B
\]

implies the condition

\[
\Psi \frac{A}{E} P B = \Psi \frac{A}{E} P' B
\]

When this is the case, we write \( \Phi \succeq_{A \to B} \Psi \).

In general, the relation of tomographic ordering (for a fixed systems \( A \) and \( B \)) may or may not have a maximum. When it does, this maximum is called a dynamically faithful state:

**Definition 12** (Dynamically faithful state) \( \Phi \) (possibly non-deterministic) state \( \Phi \in \text{St}(A \otimes R) \) is dynamically faithful for processes of type \( A \to B \) if, for every pair of processes \( P \) and \( P' \) of type \( A \to B \), the condition

\[
\Phi \frac{A}{R} P B = \Phi \frac{A}{R} P' B
\]

implies

\[
A \frac{P}{R} B = A \frac{P'}{R} B.
\]

In every theory satisfying the Displays Assumption \( \mathbb{1} \) dynamically faithful states can be taken to be deterministic without loss of generality:

**Lemma 4** (\( A_1 \)) For a generic pair of systems \( A \) and \( B \), if there exists a dynamically faithful state for processes of type \( A \to B \), then there exists a deterministic dynamically faithful state for processes of type \( A \to B \).

**Proof.** Let \( \Phi \in \text{St}(A \otimes R) \) be a (possibly non-deterministic) dynamically faithful state for processes of type \( A \to B \), and let \( \rho = (\rho_x)_{x \in X} \) be a source that produces the state \( \Phi \), say \( \rho_{x_0} = \Phi \) for some outcome \( x_0 \in X \). Since \( \Phi \) is dynamically faithful, equality of two processes on the source \( \rho \) implies equality of the processes themselves: for every pair of processes \( P \) and \( P' \) of type \( A \to B \), the condition \( (P \otimes I_R) \sim_\rho (P' \otimes I_R) \) implies the condition \( P = P' \). Then, Lemma \( \mathbb{2} \) shows that there exists a deterministic state \( \Gamma \in \text{DetSt}(A \otimes R \otimes E) \), for suitable system \( E \), such that the condition \( (P \otimes I_R \otimes I_E) \Gamma = (P' \otimes I_R \otimes I_E) \Gamma \) implies \( (P \otimes I_E) \sim_\Sigma (P' \otimes I_E) \) (and therefore \( P = P' \), in the present case). Hence, the deterministic state \( \Gamma \) is dynamically faithful for processes of type \( A \to B \). \( \blacksquare \)

D. Relation between tomographic ordering and containment

There is an important connection between the tomographic ordering and the containment relation defined earlier in the paper. Recall the definition: a deterministic state \( \rho \) contains another deterministic state \( \sigma \), denoted as \( \rho \supseteq \sigma \), if \( \rho \) is a non-trivial mixture of \( \sigma \) and some other state \( \tau \), namely \( \rho = p_0 \sigma + p_1 \tau \) where \( (p_0, p_1) \) are probabilities and \( p_0 \) is cancellative. Here we show that the containment relation orders the deterministic states according to the tomographic power of their extensions:

**Lemma 5** (\( A_1, A_3 \)) Let \( \rho \) and \( \sigma \) be two deterministic states of system \( A \). If \( \rho \) contains \( \sigma \), then for every extension of \( \sigma \), say \( \Sigma \in \text{Ext}(\sigma, E) \) there exists an extension of \( \rho \), say \( \Gamma \in \text{Ext}(\rho, F) \), such that

\[
\Gamma \succeq_{A \to B} \Sigma
\]

for every system \( B \).
The proof is provided in Appendix D.

A simple consequence of Lemma 5 is the following

**Corollary 2 (A1,A3)** Let \( \rho \) and \( \sigma \) be two deterministic states of system \( A \). If \( \rho \) contains \( \sigma \), then, for every system \( B \) and for every pair of processes \( \mathcal{P} \) and \( \mathcal{P}' \) of type \( A \to B \), the condition \( \mathcal{P} \equiv _\rho \mathcal{P}' \) implies the condition \( \mathcal{P} \equiv _\sigma \mathcal{P}' \).

The case of complete states is especially important here. In this case, we have the following

**Corollary 3 (A1,A3)** If \( \omega \in \text{DetSt}(A) \) is a complete state, then, for every system \( B \) and every pair of processes \( \mathcal{P} \) and \( \mathcal{P}' \) of type \( A \to B \), the condition \( \mathcal{P} \equiv _\omega \mathcal{P}' \) implies the equality \( \mathcal{P} = \mathcal{P}' \).

**Proof.** Immediate from Corollary 2, Lemma 3, and the definition of complete state. ■

This result plays a crucial role in the rest of the paper. In passing, we note that it also suggests an infinite-dimensional generalization of the notion of complete state [77].

### E. Necessary and sufficient condition for Dynamically Faithful States

We are now ready to provide the core technical result of the paper:

**Theorem 1 (A1,A2,A3,A4)** For a generic pair of systems \( A \) and \( B \), the following are equivalent:

1. there exists a dynamically faithful state for processes of type \( A \to B \)
2. there exists a complete state \( \omega \in \text{DetSt}(A) \) such that the set of all the extensions of \( \omega \) has a maximum with respect to the tomographic ordering \( \succeq _{A \to B} \).

The proof is provided in Appendix E. The important point of the above theorem is that one can focus the attention on the complete states. In summary, the existence of dynamically faithful states boils down to the existence of a maximally powerful extension of a complete state.

### F. Physical conditions for Dynamically Faithful States

We have seen that Dynamically Faithful States holds if and only if every complete state has a maximally powerful extension. Still, this is just a mathematical requirement. Can we find physical reasons for this requirement to be satisfied? Here we give three physically motivated sufficient conditions.

#### 1. Universal Extension

Heuristically, it is natural to imagine that the “maximally powerful extension” in Theorem 1 determines all the other ways in which the system can be correlated to an environment. Going further, we can imagine that all the other correlation can be physically generated from the “maximally powerful extension” using some (possibly non-deterministic) process. The idea motivates the notion of universal extension, from which all the extensions of a given state can be generated:

**Definition 13 (Universal extension)** A state \( \rho \in \text{St}(A) \) has a universal extension if there exists a reference system \( R \) and a state \( \Psi \in \text{St}(A \otimes R) \) with the property that every other extension of \( \rho \) can be probabilistically generated from \( \Psi \) by applying a transformation on \( R \). Explicitly: for every system \( E \), every extension \( \Gamma \in \text{Ext}(\rho, E) \) can be obtained as

\[
p \begin{array}{c|c|c|c}
  \text{A} & \Gamma & \text{E} & \Psi \\
  \text{R} & \text{T} & \text{E}
\end{array}
\]

where \( p \in \text{Transf}(I \to I) \) is a cancellative scalar and \( \mathcal{T} \) is a transformation of type \( R \to E \).

Using this definition, we can formulate a requirement for general physical theories:

**Principle 3 (Universal Extension)** Every physical system has a complete state with a universal extension.
Note that one could also consider the stronger requirement that every state have a universal extension. The reasons why we did not phrase Principle 3 are (1) universal extensions of complete states are already sufficient for process tomography, and (2) as we will see later in the paper, the possibility of conclusive teleportation guarantees the existence of a universal extension of a complete state, while in general it may not guarantee the existence of universal extensions of arbitrary states.

We now show that Universal Extension guarantees Dynamically Faithful States. The first step is the following lemma:

**Lemma 6** Suppose that a deterministic state $\rho \in \text{DetSt}(A)$ has a universal extension $\Psi \in \text{DetSt}(A \otimes R)$. Then, for every system $B$ and for every pair of processes of type $A \to B$, say $P$ and $P'$, the condition

$$\Psi \rho \begin{array}{c} A \\ \overline{R} \end{array} \begin{array}{c} P \\ B \end{array} = \Psi \rho \begin{array}{c} A \\ \overline{R} \end{array} \begin{array}{c} P' \\ B \end{array}$$

implies the condition

$$P \equiv_\rho P'.$$

**Proof.** Let $\Gamma \in \text{Ext}(\rho, E)$ be an arbitrary extension of $\rho$, and let $T \in \text{Transf}(R \to E)$ be the transformation in Eq. (40). By applying the transformation $T$ on both sides of Eq. (41), we obtain the relation

$$\Psi \rho \begin{array}{c} A \\ \overline{R} \end{array} \begin{array}{c} P \\ B \end{array} T \overline{E} = \Psi \rho \begin{array}{c} A \\ \overline{R} \end{array} \begin{array}{c} P' \\ B \end{array} T \overline{E}.$$

Inserting Eq. (40) into both sides of the equality, we then obtain

$$p \Gamma \begin{array}{c} A \\ \overline{E} \end{array} \begin{array}{c} P \\ B \end{array} = p \Gamma \begin{array}{c} A \\ \overline{E} \end{array} \begin{array}{c} P' \\ B \end{array},$$

and, since $p$ is cancellative,

$$\Gamma \begin{array}{c} A \\ \overline{E} \end{array} \begin{array}{c} P \\ B \end{array} = \Gamma \begin{array}{c} A \\ \overline{E} \end{array} \begin{array}{c} P' \\ B \end{array}$$

(cf. Lemma 1). Since $\Gamma$ is an arbitrary extension of $\rho$, we conclude that the equivalence $P \equiv_\rho P'$ holds. ■

Applying the above lemma to a complete state, we obtain the following

**Theorem 2 (A1,A3)** Universal Extension implies Dynamically Faithful States.

**Proof.** Universal Extension guarantees that there exists a complete state $\omega \in \text{DetSt}(A)$ with a universal extension $\Phi \in \text{DetSt}(A \otimes R)$, for some auxiliary system $R$. Since $\Phi$ is a universal extension, for every system $B$ and every pair of processes $P$ and $P'$ of type $A \to B$, the equality

$$(P \otimes I_R)\Phi = (P' \otimes I_R)\Phi$$

implies the condition

$$P \equiv_\omega P'.$$

(cf. Lemma 1). Now, since $\omega$ is complete, the equality on the extensions of $\omega$ implies $P = P'$ (Corollary 3). Summarizing, we obtained that the condition $(P \otimes I_R)\Phi = (P' \otimes I_R)\Phi$ implies $P = P'$. Hence, the state $\Phi$ is dynamically faithful for processes of type $A \to B$. Since this construction works for arbitrary $A$ and $B$, we conclude that the theory satisfies Dynamically Faithful States. ■

Notably, Universal Extension implies the existence of a state $\Phi \in \text{DetSt}(A \otimes B)$ which is dynamically faithful for processes of type $A \to B$, with arbitrary output system $B$. In other words, the choice dynamically faithful state depends only on the input of the tested process and not on its output.
2. Conclusive Teleportation

Quantum teleportation is a protocol for transferring the state of a quantum system from a sender to a receiver using only classical communication and previously established quantum correlations. The most basic version of quantum teleportation is probabilistic: the sender performs a measurement on the system to be teleported on part of a bipartite state, shared with the receiver. If the measurement yields the appropriate outcome, then the state of the system is transferred to the receiver without any alteration. Probabilistic teleportation is often called concludes. The analogue of conclusive teleportation in general theories was studied by Abramsky and Coecke in, in the context of categorical quantum mechanics, by Barnum, Barrett, Leifer, and Wilce in the context of general probabilistic theories, and by Chiribella, D’Ariano, and Perinotti in the context of theories satisfying Purification.

In a general physical theory, conclusive teleportation means that, for every system \( A \) there exists a system \( R \), a deterministic state \( \Phi \in \text{DetSt}(A \otimes R) \), an effect \( E \in \text{Eff}(R \otimes A) \), and a cancellative scalar \( p_A \) such that

\[
\Phi_{A \otimes R} \xrightarrow{A \rightarrow E} p_A \Phi_{A \otimes A} = p_A A_{A \otimes A}.
\]  

(48)

The existence of conclusive teleportation is a valuable operational feature, and may be put forward as a desideratum for general physical theories:

**Principle 4 (Conclusive Teleportation)** For every physical system \( A \), there exists a conclusive teleportation protocol as in Eq. (48).

Modulo a few technical differences, Conclusive Teleportation coincides with the main axiom for compact closer categories in categorical quantum mechanics. In this context, it is known that the teleportation state \( \Phi \) induces a one-to-one correspondence between processes and bipartite states. In other words, \( \Phi \) is dynamically faithful for processes of type \( A \rightarrow B \), with arbitrary \( B \). Here we show a stronger result, namely that the state \( \Phi \) is the universal extension of a complete state:

**Proposition 2 (A4)** Let \( \Phi \in \text{DetSt}(A \otimes R) \) be a teleportation state for system \( A \). Then, \( \Phi \) is the universal extension of a complete state.

The proof is provided in Appendix where we also observe that, in general, a theory with conclusive teleportation may not have universal extensions for arbitrary states.

A simple consequence of Proposition 2 is the following:

**Corollary 4 (A4)** Conclusive Teleportation implies Universal Extension.

Summarizing, we proved the chain of implications:

- Conclusive Teleportation \( \implies \) Universal Extension
- \( \implies \) Dynamically Faithful States
- \( \implies \) Dynamically Faithful Systems.

In short, the possibility of conclusive teleportation guarantees the feasibility of process tomography, even in theories that violate Local Tomography.

3. Purification

A purification of a given state is an extension of that state to a pure state of a composite system. In the standard scenario where the state space of physical systems is a convex set, pure states are defined as the extreme points of the convex set. A diagrammatic definition of pure state, valid also for theories where the scalars are not real numbers, was provided in Ref. \( [76] \). The second definition is equivalent to the first in every theory satisfying Causality, the requirement that it should be impossible to “send signals from the future to the past” (see below for a more precise mathematical statement) and Local Tomography, or Local Tomography on Pure States (a weakening of Local Tomography satisfied by quantum theory on real vector spaces).

In the following, we will not commit to a specific definition of pure state. Instead, we will simply assume that for every system \( A \) there exists a set of states \( \text{PurSt}(A) \), called pure, and satisfying the condition

\[
\alpha \in \text{PurSt}(A), \beta \in \text{PurSt}(B) \implies \alpha \otimes \beta \in \text{PurSt}(A \otimes B).
\]  

(49)
We call the above condition Pure Product States. Pure Product States is automatically satisfied by the diagrammatic
definition of pure state in [76]. It is also satisfied by the usual definition of pure states as extreme points, when it
coincides with the definition in [76].

Let us now review the notion of purification. In its basic form, purification is formulated in theories satisfying
Causality. An equivalent condition for Causality is the existence of a unique deterministic effect:

**Proposition 3 ([24])** A theory satisfies Causality if and only if for every system \( A \) there exists a unique deterministic
effect \( u_A \in \text{DetEff}(A) \).

Theories satisfying Causality are often called causal theories. In a causal theory, a state \( \Gamma \in \text{St}(A \otimes E) \) is an
extension of another state \( \rho \in \text{St}(A) \) if the condition

\[
\begin{array}{c}
\begin{array}{c}
\Gamma_A \\
E
\end{array}
\end{array}
= \begin{array}{c}
\begin{array}{c}
\rho_A \\
E
\end{array}
\end{array}
\tag{50}
\]

is satisfied.

We are now ready to state the Purification principle in its basic form:

**Principle 5 (Purification)** For a theory satisfying Causality and Pure Product States,

1. every state should have a purification: for every system \( A \in \text{Sys} \) and every deterministic state \( \rho \in \text{DetSt}(A) \)
there exists a system \( R \) and a deterministic pure state \( \Psi \in \text{PurSt}(A \otimes R) \) such that

\[
\begin{array}{c}
\begin{array}{c}
\Psi_A \\
R
\end{array}
\end{array}
= \begin{array}{c}
\begin{array}{c}
\rho_A \\
R
\end{array}
\end{array}
\tag{51}
\]

2. every two purifications with the same purifying system should be interconvertible via a local symmetry trans-
formation: for every system \( R \), and every pair of deterministic pure states \( \Psi \) and \( \Psi' \) in \( \text{PurSt}(A \otimes R) \), the condition

\[
\begin{array}{c}
\begin{array}{c}
\Psi'_{A} \\
R
\end{array}
\end{array}
= \begin{array}{c}
\begin{array}{c}
\Psi_{A} \\
R
\end{array}
\end{array}
\tag{52}
\]

implies that there exists a reversible transformation \( U : R \rightarrow R \) such that

\[
\begin{array}{c}
\begin{array}{c}
\Psi'_{A} \\
R
\end{array}
\end{array}
= \begin{array}{c}
\begin{array}{c}
\Psi_{A} \\
R
\end{array}
\end{array}
U
\tag{53}
\]

Remarkably, the symmetry property of purifications implies that every purification is a universal extension:

**Proposition 4** Let \( \rho \in \text{DetSt}(A) \) be an arbitrary state of an arbitrary system \( A \), and let \( \Gamma \in \text{DetSt}(A \otimes E) \) be an
arbitrary extension of \( \rho \). If the theory satisfies Causality, Pure Product States, and Purification, then the state \( \Gamma \) can be generated as

\[
\begin{array}{c}
\begin{array}{c}
\Gamma_A \\
E
\end{array}
\end{array}
= \begin{array}{c}
\begin{array}{c}
\Psi_A \\
R
\end{array}
\end{array}T
\tag{54}
\]

where \( \Psi \in \text{PurSt}(A \otimes R) \) is an arbitrary purification of \( \rho \) and \( T \in \text{DetTransf}(R \rightarrow E) \) is a deterministic transformation.

The proof is provided in Appendix G. The obvious consequence of Proposition 4 is the following

**Corollary 5 (A1,A3,A4)** If a theory satisfies Causality, Pure Product States, and Purification, then it satisfies
Universal Extension, and, in particular, Dynamically Faithful States.

**Proof.** Proposition 4 shows that every purification of a given state \( \rho \) is a universal extension, in the sense of Definition E. In particular, every complete state has a universal extension (complete states exist by Assumption H). Hence, the principle of Universal Extension is satisfied. Then, Theorem E guarantees that Dynamically Faithful States holds. □
Summarizing, we proved the chain of implications:

\[
\text{Causality, Pure Product States, Purification } \implies \text{Universal Extension} \\
\implies \text{Dynamically Faithful States} \\
\implies \text{Dynamically Faithful Systems.}
\]

Note that this is the same chain of implications as in the previous subsection, except that “Conclusive Teleportation” is now replaced by “Causality + Pure Product States + Purification.” A natural question is whether there are relations between Purification and Conclusive Teleportation. When the scalars are real numbers in the interval \([0, 1]\), it is known that Purification implies Conclusive Teleportation \([24, 27, 28, 13]\). More generally, it is also possible to show that Purification implies Conclusive Teleportation in every theory that satisfies two additional axioms of Pure Sharpness and Purity Preservation \([52, 78, 79]\).

IV. CONCLUSIONS

In this paper we analyzed the task of process tomography in general physical theories, exploring the requirement that physical processes should be identifiable by their action on a finite set of auxiliary systems/a finite set of input states. Most of the paper focused on the requirement that physical processes can be identified by their action on a single state, called dynamically faithful. The existence of dynamically faithful states is a broader condition than the usual principle of Local Tomography, and is satisfied in a number of variants of quantum theory, including quantum theory on real Hilbert spaces and a Fermionic version of quantum theory \([50, 51]\). It is natural to conjecture that dynamically faithful states exist also in a recent extension of standard quantum theory that includes complex, real, and quaternionic Hilbert spaces in a single theory \([52]\). A formal proof of this statement, however, is currently missing and remains as an interesting direction for future research.

One of our main results is that the existence of dynamically faithful states can be guaranteed by a simple physical condition, namely that complete states have a universal extension from which all the other extensions can be generated with non-zero probability. Example of physical theories with this property are the set of theories where conclusive teleportation is possible, and the set of theories satisfying the Causality, Pure Product States, and Purification. For every theory satisfying Causality, Pure Product States, and Purification, process tomography can be achieved using a single bipartite state: specifically, the purification of any complete state of a given system \(A\) can be used to characterize all the processes with input system \(A\) and arbitrary output system \(B\).

An important observation is that the existence of dynamically faithful states is independent of the Causality axiom, that is, the requirement that the outcome probabilities of present experiments are independent of the choice of future experiments. This observation suggests that the possibility of characterizing physical processes may have a more primitive role than considerations of causality, and that one could adopt Dynamically Faithful States as a foundational principle for general physical theories where causality is emergent.

Acknowledgements. I wish to thank Mauro D’Ariano for introducing me to quantum tomography and to the problem of deriving quantum theory from physical principles. The discussions we had during my PhD and early postdoc years have been the seeds for much of the ideas developed in this paper. I also wish to acknowledge discussions with Paolo Perinotti and Carlo Maria Scandolo on the relations between purification and the existence of dynamically faithful states. Appendix A: A converse of Proposition 1

Bipartite states from which other states can be probabilistically generated were introduced in the early work by D’Ariano [13,18], where they were called *preparationally faithful*. Originally [13,16], the term referred to states of a bipartite system A⊗B with the property that every state of A can be probabilistically generated by a physical transformation on B. In later works [17,18], the term was used for states with the property that every joint state of A⊗B can be probabilistically generated by a physical transformation on B. Here we adopt the second definition and extend it to (1) transformations with different inputs and outputs, and (2) theories where the scalars are not necessarily real numbers:

**Definition 14** A state \( \Phi \in \text{St}(A \otimes S) \) is preparationally faithful from S to B if every state \( \rho \in \text{St}(A \otimes B) \) can be probabilistically obtained as

\[
p \left( \begin{array}{c}
\rho \\
A \\
B
\end{array} \right) = \left( \begin{array}{c}
\Phi \\
S \\
A \otimes S \\
B
\end{array} \right),
\]

(A1)
where \( p \in \text{Transf}(I \to I) \) is a cancellative scalar and \( S \) is a transformation of type \( S \to B \).

Using the above definition, we introduce a notion of doubly preparationally faithful theories:

**Definition 15** A theory is doubly preparationally faithful if for every pair of systems \( A \) and \( B \) there exists a system \( S \) and a state \( \Phi \in \text{St}(A \otimes S) \) that is preparationally faithful from \( A \) to \( A \) and from \( S \) to \( B \).

Concrete examples of doubly preparationally faithful theories are finite-dimensional classical probability theory and quantum theory, both on complex and on real vector spaces. In quantum theory, the maximally entangled state \(|\Phi\rangle = \sum k l c_{kl} |k\rangle \otimes |l\rangle /\sqrt{d} \) of system \( A \otimes S \), with \( S \simeq A \), is preparationally faithful from \( S \) to \( B \) with arbitrary \( B \).

Indeed, every pure state \(|\Psi\rangle = \sum_{k,l} c_{kl} |k\rangle \otimes |l\rangle \) of the composite system \( A \otimes B \) can be probabilistically obtained from the maximally entangled state as \(|\Psi\rangle \propto (I_A \otimes K) |\Phi\rangle\), where \( K = \sum_{k,l} c_{kl} |k\rangle \langle l| / \|c^i c\| \) is a suitable Kraus operator, \( c \) is the matrix with matrix elements \( c_{kl} \), and \( \parallel c^i c\parallel \) is the maximum eigenvalue of \( c^i c \). Since every pure state can be generated probabilistically from \(|\Phi\rangle\), the same holds for mixed states (in finite dimensions). This shows that \(|\Phi\rangle\) is preparationally faithful from \( S \) to \( B \), with arbitrary \( B \). A similar argument shows that \(|\Phi\rangle\) is preparationally faithful from \( A \) to \( A \).

More generally, every process theory where the processes form a compact closed category \([45, 50, 62]\) is doubly preparationally faithful. Physically, these are the theories where every system \( A \) comes with a dual system \( S \), such that there exists a state of \( A \otimes S \) that allows for conclusive teleportation of states of \( A \), as well as conclusive teleportation of states of \( S \).

With the above definitions, we have the following proposition:

**Proposition 5** (A3) For a doubly preparationally faithful theory, the following are equivalent:

1. Local Tomography holds
2. standard process tomography completely identifies physical processes, that is, Eq. (18) implies Eq. (20).

**Proof.** Since the implication 1 \(\Rightarrow\) 2 was already proved by Proposition 1, we only need to prove the implication 2 \(\Rightarrow\) 1.

Let \( A \) and \( B \) be two generic systems, and let \( \rho \) and \( \rho' \) be two generic states of the composite system \( A \otimes B \). Our goal is to show that then the condition

\[
\rho \begin{array}{c} A \\ B \end{array} = \rho' \begin{array}{c} A \\ B \end{array} \quad \forall a \in \text{Eff}(A) \\
\forall b \in \text{Eff}(B) \tag{A2}
\]

implies \( \rho = \rho' \).

Let us assume that Eq. (A2) holds. Since the theory is doubly preparationally faithful, there exists a system \( S \) and a state \( \Phi \in \text{St}(A \otimes S) \) that is preparationally faithful from \( A \) to \( A \) and from \( S \) to \( B \). Since \( \Phi \) is preparationally faithful from \( S \) to \( B \), there exist two cancellative scalars \( p \) and \( p' \), and two transformations \( S \) and \( S' \), of type \( S \to B \), such that

\[
p \begin{array}{c} \rho \\ B \end{array} = \begin{array}{c} \Phi \\ S \end{array} \begin{array}{c} A \\ B \end{array}, \tag{A3}
\]

and

\[
p' \begin{array}{c} \rho' \\ B \end{array} = \begin{array}{c} \Phi \\ S \end{array} \begin{array}{c} A \\ S' \end{array} \begin{array}{c} S \rangle \rangle B \end{array}. \tag{A4}
\]

Since the state \( \Phi \) is preparationally faithful from \( A \) to \( A \), for every state \( \Sigma \in \text{St}(A \otimes S) \) there exists a cancellative scalar \( q \) and transformation \( \mathcal{T} \) of type \( A \to A \) such that

\[
q \begin{array}{c} \Sigma \\ S \end{array} = \begin{array}{c} \Phi \\ T \end{array} \begin{array}{c} A \\ A \end{array} \begin{array}{c} T \rangle \rangle A \end{array}. \tag{A5}
\]

Inserting this relation into Eqs. (A3) and (A4), we obtain

\[
p \begin{array}{c} \rho \\ B \end{array} \begin{array}{c} \mathcal{T} \\ A \end{array} = q \begin{array}{c} \Sigma \\ S \end{array} \begin{array}{c} A \\ B \end{array} \begin{array}{c} S \rangle \rangle B \end{array}, \tag{A6}
\]

as desired.
Now, note that $p' S$ and $p S'$ are physical transformations, due to the Randomizations Assumption. For these two transformations, we have the relation

$$q \left( \begin{array}{c} \Sigma^A \\ S \\ p' S \\ B \\ B \end{array} \right) = pp' \left( \begin{array}{c} \rho^A \\ T \\ A \\ A \\ B \end{array} \right) \left( \begin{array}{c} a' \\ B \\ B \end{array} \right),$$

where the second equality follows from Eq. (A2), applied to

$$A\ a := A T A\ a'. \quad (A9)$$

Recall that $\Sigma$ is a generic state of system $A \otimes S$. In particular, we can choose $\Sigma$ to be of the product form $\Sigma = \alpha \otimes \sigma$. With this choice, Eq. (A8) becomes

$$q \left( \begin{array}{c} \alpha^A \\ S \\ p' S \\ B \\ B \end{array} \right) = q \left( \begin{array}{c} \alpha^A \\ S \\ p S' \\ B \\ B \end{array} \right) \ \forall a' \in \text{Eff}(A)$$

Choosing $\alpha$ to be a deterministic state and $a'$ to be a deterministic effect, we then obtain

$$q \left( \begin{array}{c} \sigma^A \\ S \\ p' S \\ B \\ B \end{array} \right) = q \left( \begin{array}{c} \sigma^A \\ S \\ p S' \\ B \\ B \end{array} \right) \ \forall b \in \text{Eff}(B). \quad (A11)$$

Since $q$ is cancellative for every $\alpha$ and $\sigma$, we then obtain

$$q \left( \begin{array}{c} \sigma^A \\ S \\ p' S \\ B \\ B \end{array} \right) = q \left( \begin{array}{c} \sigma^A \\ S \\ p S' \\ B \\ B \end{array} \right) \ \forall b \in \text{Eff}(B). \quad (A12)$$

To conclude, recall that $\sigma$ is an arbitrary state, and therefore the above equation implies that the processes $p S'$ and $p' S$ give rise to the same outcome probability in every setup of standard process tomography. Since by hypothesis standard process tomography successfully identifies physical processes, we conclude that the equality $p S' = p' S$ must hold. Using this fact and Eqs. (A3) and (A4), we obtain

$$pp' \left( \begin{array}{c} \rho^A \\ S \\ p' S \\ B \end{array} \right) = pp' \left( \begin{array}{c} \rho^A \\ S \\ p S' \\ B \end{array} \right) = pp' \left( \begin{array}{c} \rho^A \\ B \end{array} \right).$$

Since $p$ and $p'$ are both cancellative, we conclude that the equality $\rho = \rho'$ must hold. ■
Appendix B: Properties of the relations $≡_ρ$ and $=_ρ$

We start by showing that the relation $≡_ρ$ is stronger than the relation $=_ρ$.

**Proof of Lemma** [2] Let $ρ = (ρ_x)_{x ∈ X}$ be a source with average state $ρ$. The Display Assumption guarantees that the states in $ρ$ can be prepared as

$$\rho_x^A = \Gamma^A_{E e_x} \hspace{1cm} \forall x ∈ X \tag{B1}$$

for some system $E$, some deterministic state $Γ$, and some measurement $e = (e_x)_{x ∈ X}$. Now, the state $Γ$ is an extension of $ρ$: indeed, one has

$$\rho^A = \sum_{x ∈ X} \rho_x^A = \sum_{x ∈ X} \Gamma^A_{E e_x} = \Gamma^A_{E u_E} \tag{B2}$$

where $e$ is the deterministic effect $e := \sum_{x ∈ X} e_x$ (the last equality follows from Eq. (9)).

Now, suppose that the condition

$$\Gamma^A_{E P B} = \Gamma^A_{E P' B} \tag{B3}$$

holds. Applying the effect $e_x$ on both sides, one then obtains

$$\Gamma^A_{E P e_x B} = \Gamma^A_{E P' e_x B} \tag{B4}$$

and, using Eq. (B1),

$$\rho_x^A P B = \rho_x^A P' B \hspace{1cm} \forall x ∈ X. \tag{B5}$$

We now show that the two relations $≡_ρ$ and $=_ρ$ are equivalent in theories satisfying Causality and Local Tomography. We recall that Causality is equivalent to the existence of a unique deterministic effect $u_A$ for every system $A$ [24, 43, 47–49].

We can then prove the following proposition:

**Proposition 6 (A1)** Suppose that a theory satisfies Causality and Local Tomography. Then, for every system $A$, every deterministic state $ρ ∈ \text{DetSt}(A)$, and every pair of processes $P$ and $P'$, of type $A → B$, one has the condition

$$P ≡_ρ P' \iff P =_ρ P'. \tag{B6}$$

**Proof.** We know from Corollary [1] that the condition $P ≡_ρ P'$ implies the condition $P =_ρ P'$. To prove the equivalence, we only need to show the converse implication. Suppose that the condition $P =_ρ P'$ holds. Then, let $Γ$ be a generic extension of $ρ$ on system $E$, namely

$$\rho^A = \Gamma^A_{E u_E}. \tag{B7}$$
Here we used the Causality Axiom, which guarantees that there exists only one deterministic effect for system E. At this point, we need to prove the relation

\[
\Gamma_A \otimes E \overset{\Delta \subset E}{\rightarrow} A \otimes P \otimes \Gamma_B \otimes E \quad (B8)
\]

To this purpose, pick an arbitrary measurement \(e = (e_x)_{x \in X}\) and define the preparation test \(\rho = (\rho_x)_{x \in X}\) as

\[
(\rho_x)_A := \Gamma_A \otimes E \overset{e_x}{\rightarrow} A \otimes P \otimes \Gamma_B \otimes E \quad (B9)
\]

Note that the preparation test \(\rho\) has average state \(\rho\): indeed, one has

\[
\sum_{x \in X} (\rho_x)_A = \Gamma_A \otimes E \overset{u_E}{\rightarrow} A \otimes P \otimes \Gamma_B \otimes E \quad (B10)
\]

having used Eq. (B7) and the fact that \(u_A\) is the only deterministic effect on system A. Since the preparation test \(\rho\) averages to \(\rho\), the condition \(P = \rho \iff P'\) implies

\[
(\rho_x)_A \otimes P \otimes \Gamma_B \otimes E = (\rho_x)_A \otimes P' \otimes \Gamma_B \otimes E \quad \forall x \in X \quad (B11)
\]

and, using the definition of \(\rho_x\) in Eq. (B9),

\[
\Gamma_A \otimes E \overset{e_x}{\rightarrow} A \otimes P \otimes \Gamma_B \otimes E = (\rho_x)_A \otimes P \otimes \Gamma_B \otimes E \quad \forall x \in X \quad (B12)
\]

To conclude, note that for a generic measurement \(b = (b_y)_{y \in Y}\) one has

\[
\Gamma_A \otimes E \overset{b_y}{\rightarrow} A \otimes P \otimes \Gamma_B \otimes E = (\rho_y)_A \otimes P \otimes \Gamma_B \otimes E \quad \forall x \in X \quad (B13)
\]

for every \(x \in X\) and for every \(y \in Y\). Since the two measurements \(b\) and \(e\) are generic, Local Tomography implies Eq. (B8). Since \(\Gamma\) is a generic extension of \(\rho\), we conclude that \(P \equiv \rho \iff P'\). \(\blacksquare\)

**Appendix C: Proof of Lemma 3**

The direction \(\Rightarrow\) is immediate. To prove the direction \(\Leftarrow\), let us assume the condition \(P \equiv\rho \iff P'\) for every deterministic state \(\rho\). Recall that two processes \(P\) and \(P'\) are equal if and only if

\[
\Gamma_A \otimes E \overset{P}{\rightarrow} A \otimes P \otimes \Gamma_B \otimes E = \Gamma_A \otimes E \overset{P'}{\rightarrow} A \otimes P' \otimes \Gamma_B \otimes E \quad (C1)
\]

for every system \(E\) and for every (possibly non-deterministic) state \(\Gamma \in \mathcal{St}(A \otimes E)\).

Let us pick a generic \(E\) and a generic \(\Gamma\). Since every state can be prepared in some test (by the Displays Assumption \(\mathfrak{D}\)), there must exist a test \(\Delta = (\Delta_x)_{x \in X}\) and an outcome \(x_0 \in X\) such that

\[
\Delta_{x_0} = \Gamma \quad (C2)
\]

Now, let us define the deterministic states

\[
\Delta := \sum_{x \in X} \Delta_x \quad (C3)
\]
and

\[
\begin{array}{c}
\begin{array}{c}
\Delta \\
E \\
\end{array}
\end{array}
\]  

\( \equiv \rho \)  \quad \equiv \quad \begin{array}{c}
\begin{array}{c}
\rho \\
E \\
\end{array}
\end{array}
\]  

where \( e \) is a fixed, but otherwise arbitrary, deterministic effect on system \( E \). By construction, \( \Delta \) is an extension of \( \rho \). Hence, every extension of \( \Delta \) is also an extension of \( \rho \). As a consequence, one has the implication

\[
P \equiv \rho \quad P' \implies P \otimes I_E \equiv \Delta \otimes I_E.
\]

Moreover, one has the implications

\[
P \otimes I_E \equiv \Delta \quad P' \otimes I_E \implies P \otimes I_E = \Delta \otimes I_E
\]

(by Corollary [1]) and

\[
P \otimes I_E = \Delta \quad P' \otimes I_E \implies (P \otimes I_E) \Delta_x = (P' \otimes I_E) \Delta_x,
\]

for every outcome \( x \) (by definition of equality upon input of \( \Delta \)). Choosing \( x = x_0 \) and using Eq. (C2), we finally obtain Eq. (C1). Since the system \( E \) and the state \( \Gamma \) are generic, the equality \( P = P' \) follows. ■

Appendix D: Proof of Lemma [5]

Suppose that \( \rho \) is a mixture of \( \sigma \) and \( \tau \) with probabilities \( (p_0, p_1) \), namely

\[
\begin{array}{c}
\begin{array}{c}
\rho \\
E \\
\end{array}
\end{array}
\]  

\( = \quad \begin{array}{c}
\begin{array}{c}
\sigma \\
E \\
\end{array}
\end{array} + \begin{array}{c}
\begin{array}{c}
\tau \\
E \\
\end{array}
\end{array}
\]

(D1)

Let \( \Sigma \) be an extension of \( \sigma \) on system \( E \), so that

\[
\begin{array}{c}
\begin{array}{c}
\Sigma \\
E \\
\end{array}
\end{array}
\]  

\( = \begin{array}{c}
\begin{array}{c}
\sigma \\
E \\
\end{array}
\end{array}
\]

(D2)

for some deterministic effect \( e \). Let \( \eta \) be a deterministic state of system \( E \) and let \( \Theta \) be the extension of \( \tau \) defined by \( \Theta := \tau \otimes \eta \), so that

\[
\begin{array}{c}
\begin{array}{c}
\Theta \\
E \\
\end{array}
\end{array}
\]  

\( = \begin{array}{c}
\begin{array}{c}
\tau \\
E \\
\end{array}
\end{array}
\]

(D3)

Then, define the randomized preparation test \( \Delta := (\Delta_1, \Delta_2) \), with \( \Delta_1 = p_0 \Sigma \) and \( \Delta_2 = p_1 \Theta \) (the randomized preparation \( \Delta \) is a valid test due to the Randomization Assumption [5]). The Displays Assumption[II]guarantees that the states \( \Delta_1 \) and \( \Delta_2 \) can be generated as

\[
\begin{array}{c}
\begin{array}{c}
\Delta_i \\
E \\
\end{array}
\end{array}
\]  

\( \equiv \quad \begin{array}{c}
\begin{array}{c}
\Gamma \\
E \\
\end{array}
\end{array}
\]

(D4)
for some system $F$, some deterministic state $\Gamma$, and some measurement $f = (f_1, f_2)$. By construction, $\Gamma$ is an extension of $\rho$: indeed, defining the deterministic effect $f := f_1 + f_2$, one has

$$
\Gamma = \sum_{i=1,2} \Delta_i A E c_1 + \sum_{i=1,2} \Delta_i A E c_2 = p_0 \sum_{i=1,2} \Theta A E c_1 + p_1 \sum_{i=1,2} \Theta A E c_2.
$$

(D5)

Now, suppose that $P$ and $P'$ are two processes of type $A \to B$ and suppose that the relation

$$
\Gamma P A E F = \Gamma P' A E F (D6)
$$

holds. Applying the effect $f_1$ on both sides, we then obtain

$$
\Gamma A P A E F = \Gamma A P' A E F
$$

(D7)

and therefore

$$
p_0 \sum_{i=1,2} \Theta A E c_1 = p_0 \sum_{i=1,2} \Theta A E c_2.
$$

(D8)

Since $p_0$ is cancellative, the two processes $P$ and $P'$ must coincide on $\Sigma$ (cf. Lemma 1). Hence, one has $\Gamma \succeq_{A\to B} \Sigma$.

Appendix E: Proof of Theorem 1

Proof of 2 $\implies$ 1. Suppose that there exists a complete state, call it $\omega \in \text{DetSt}(A)$, such that the set of all extensions of $\omega$ has a maximum with respect to the tomographic ordering $\succeq_{A\to B}$. Let $\Phi \in \text{Ext}(\omega, R)$ be such maximum, for some auxiliary system $R$, and let $P$ and $P'$ be two arbitrary processes of type $A \to B$. By definition, the condition $(P \otimes I_R) \Phi = (P' \otimes I_R) \Phi$ implies the equivalence $P \equiv_{\omega} P'$. In turn, the condition $P \equiv_{\omega} P'$ implies $P = P'$ (Corollary 3). Hence, we obtained that the condition $(P \otimes I_R) \Phi = (P' \otimes I_R) \Phi$ implies $P = P'$, meaning that $\Phi$ is dynamically faithful for processes of type $A \to B$.

Proof of 1 $\implies$ 2. Let $\Phi \in \text{St}(A \otimes R)$ be a dynamically faithful state for processes of type $A \to B$. Without loss of generality, the state $\Phi$ can be taken to be deterministic (Lemma 4). Then, let us pick a deterministic effect on system $R$, say $r \in \text{DetEff}(R)$, and define the state

$$
\phi := \Phi R^t A.
$$

(E1)
By construction, $\Phi$ is an extension of $\phi$. If $\phi$ is a complete state, this concludes the proof: the complete state $\phi$ has an extension $\Phi$ that is a (global) maximum with respect to the tomographic ordering $\succeq_{A\rightarrow B}$.

If $\phi$ is not complete, we can pick a complete state $\sigma \in \text{DetSt}(A)$, an arbitrary deterministic state $\psi \in \text{DetSt}(R)$, and, using the Randomizations Assumption 3, we can define the source $\rho = (\rho_0, \rho_1)$ with $\rho_0 := p_0 \Phi$ and $\rho_1 := p_1 \sigma \otimes \psi$, where $(p_0, p_1)$ is a probability distribution such that $p_0$ and $p_1$ are both cancellative (the existence of such probability distribution is guaranteed by the Coins Assumption 2). Note that the condition $(P \otimes I_R \otimes I_E) \Gamma = (P' \otimes I_R \otimes I_E) \Gamma$ implies $p_0 (P \otimes I_R) \Phi = p_0 (P' \otimes I_R) \Phi$, which in turn implies $(P \otimes I_R) \Phi = (P' \otimes I_R) \Phi$ (because $p_0$ is cancellative) and $P = P'$ (because $\Phi$ is dynamically faithful). Now, let us denote by $\rho := \rho_0 + \rho_1 = p_0 \Phi + p_1 \sigma \otimes \psi$ the average state of the source $\rho$. Note that one has

\[
\begin{align*}
(\rho) &= p_0 (\Phi) + p_1 (\psi) \\
&= p_0 (\phi) + p_1 (\sigma) \\
&= (\omega),
\end{align*}
\]

where the state $\omega := p_0 \phi + p_1 \sigma$ is complete (because $\omega$ contains $\sigma$, and $\sigma$ is complete). Then, Lemma 2 guarantees that there exists a deterministic state $\Gamma \in \text{Ext}(\rho, E)$ such that the condition $(P \otimes I_R \otimes I_E) \Gamma = (P' \otimes I_R \otimes I_E) \Gamma$ implies $(P \otimes I_R) \sim P' (P' \otimes I_R)$, and therefore $P = P'$. Hence, the deterministic state $\Gamma$ is dynamically faithful. Note that $\Gamma$ is an extension of $\rho$, which in turn is an extension of the complete state $\omega$ (by Eq. (E2)). Summarizing, $\Gamma$ is an extension of a complete state and is a (global) maximum with respect to the tomographic ordering $\succeq_{A\rightarrow B}$. ■

Appendix F: Relations between Conclusive Teleportation and Universal Extension

Let us start by proving Proposition 2 which states that every teleportation state is the universal extension of a complete state.

**Proof of Proposition 2** Let $(E, F)$ be a binary measurement satisfying the teleportation equation (48). Let $\omega$ be a complete state of system $A$ (the existence of such state is guaranteed by Assumption 4). Let us define the state

\[
\begin{align*}
(\omega) := (\Phi) &
\end{align*}
\]

where $T := E + F$ is the deterministic effect obtained by coarse-graining over the binary measurement $(E, F)$. By construction, $\Phi$ is an extension of $\chi$. Moreover, $\chi$ is complete. To prove it, we pick an arbitrary deterministic state $\rho$ and write $\omega$ as $\omega = p_0 \rho + p_1 T$ for some state $\tau$ and for some binary probability distribution $(p_0, p_1)$ such that $p_0$ is
cancellative. Inserting this expression in Eq. (F1), we obtain

\[
\chi_A = p_0 \Phi_{RA} + p_1 \Phi_{RT}
\]

\[
= p_0 \Phi_{RE} + p_0 \Phi_{RF}
\]

\[
+ p_1 \Phi_{TA}
\]

Since \(p_0\) and \(p_A\) are both cancellative, \(p_0p_A\) is cancellative, and therefore \(\chi\) contains \(\rho\). Since \(\rho\) is arbitrary, we conclude that \(\chi\) is complete.

It remains to prove that \(\Phi\) is a universal extension of \(\chi\). This is easily done using the teleportation equation (48). Suppose that \(\Gamma \in \text{Ext}(\chi, E)\) is another extension of \(\chi\). Then, one has

\[
p_A \Gamma_{AE} = \Phi_{RAE} + \Gamma_{AE} = \Phi_{RTE},
\]

with

\[
\Gamma_{RE} := R_{TE}
\]

In summary, the extension \(\Gamma\) is probabilistically obtained from the teleportation state \(\Phi\). Since \(\Gamma\) is arbitrary, \(\Phi\) is a universal extension.

It is worth observing that the proof of Proposition 2 also implies a stronger result: in fact, every bipartite state of the composite \(A \otimes E\), with arbitrary \(E\), can be probabilistically generated from the teleportation state \(\Phi\) by means of a physical transformation. In other words, the state \(\Phi\) is preparationally faithful from system \(R\) to system \(E\), in the sense of Definition 14.
It is also worth noting that Conclusive Teleportation does not imply, in general, that every state has a universal extension. A condition that would imply universal extensions for a generic state $\rho$ is the existence of conclusive teleportation protocols of the form

$$
\Psi_A =_\rho \rho \hspace{1cm} p_e \hspace{1cm} I_A \rightarrow \Lambda_A,
$$

where $\Psi$ is an extension of $\rho$, $F$ is a suitable effect, and $p_e$ is a cancellative scalar.

**Proposition 7** If Eq. (F5) is satisfied, then the state $\Psi$ is a universal extension of $\rho$.

**Proof.** Suppose that $\Gamma \in \text{Ext}(\rho, E)$ is another extension of $\rho$. Then, Eq. (F5) implies the relation

$$
p_e \Gamma_A =_\Psi \left( \begin{array}{c}
\Psi \\
A \\
R \\
E
\end{array} \right) =_\Gamma \\
\left( \begin{array}{c}
\Gamma \\
A \\
R \\
E
\end{array} \right),
$$

with

$$
R \rightarrow E := \left( \begin{array}{c}
R \\
A \\
F \\
E
\end{array} \right),
$$

In summary, the extension $\Gamma$ is probabilistically obtained from the teleportation state $\Psi$. Since $\Gamma$ is arbitrary, $\Psi$ is a universal extension. ■

However, Eq. (F5) does not appear as a particularly compelling requirement for general physical theories, and therefore we did not include it in our formulation of Conclusive Teleportation.

**Appendix G: Proof of Proposition 4**

Let $\Phi \in \text{PurSt}(A \otimes E \otimes F)$ be a purification of the state $\Gamma$, with purifying system $E$. Since $\Gamma$ is an extension of $\rho$, $\Phi$ is also a purification of $\rho$, with purifying system $E \otimes F$. Now, pick an arbitrary deterministic pure state of $R$, say $\varphi \in \text{PurSt}(R)$, and an arbitrary deterministic pure state of $E \otimes F$, say $\psi \in \text{PurSt}(E \otimes F)$. Then, Pure Product States guarantees that the two states $\Phi \otimes \varphi$ and $\Psi \otimes \psi$ are both pure. By construction, both states are purifications of $\rho$. Hence, the symmetry property of purifications implies that there exists a reversible process $U : R \otimes E \otimes F \rightarrow E \otimes F \otimes R$ such that

$$
\left( \begin{array}{c}
\Phi \\
E \\
F \\
R
\end{array} \right) =_U \\
\left( \begin{array}{c}
\Psi \\
R \\
E \\
F \\
U \\
R
\end{array} \right).
$$
Applying the deterministic effect to system $F \otimes R$ we then obtain the condition
\[ \Gamma A E = \Phi E F U R U F E \]
\[ = \Psi R E U F E \]
\[ = \Phi A E F U R U F E \]
\[ = \Psi R E U F E \]
\[ \text{(G2)} \]

having defined
\[ R E : = R E U F E \]
\[ \text{(G3)} \]
