Key words: artichoke leaves extract; Solcoseryl; alcoholic placental dysfunction, postnatal development of infant rats

The experimental research of the artichoke (Cynara scolymus) leaves extract (ALE) influence on the postnatal development of the 1st generation rats born by female rats with the ethanol-induced placental dysfunction (PD) has been conducted. It has been found that the therapeutic and preventive regimen of ALE and the reference medicine Solcoseryl from the 14th to the 19th day of gestation (on the background of introduction of 40% ethanol solution in the dose of 4 g/kg) reduced the level of death in infant rats: ALE in 2.4 times and Solcoseryl in 1.6 times compared to the untreated control. The medicines studied caused a significant weight gain in rats compared to the control pathology group. From the 1st to 14th days of the experiment the weight gain caused by ALE was more significant. The difference in the efficacy of the medicines was not further observed. Introduction of ALE and Solcoseryl also promoted the correction of pathological deviations in the postnatal development of infant rats. Moreover, ALE showed a higher activity compared to Solcoseryl. Therefore, the data obtained allow to recommend ALE for the preventive correction of alcoholic embryopathy developed on the background of PD.

Alcoholism is referred to the medical and social risk factors of the placental dysfunction (PD) development. Recently increase of alcohol consumption by pregnant women has been observed; as a result, the number of alcoholic PD development cases increases. For example, official statistical data show that the share of such women in the USA is 3-10%, in Ukraine is about 10% [4, 7, 10]. It is known that alcohol can cross the placental barrier; accumulate in the amniotic fluid and have not only the embryolethal, teratogenic, but also the general toxic effect on a fetus [6, 8, 11]. It results in formation of the fetal alcoholic syndrome, which is characterized with growth retardation, mainly expressed within the first months and years of the postnatal period, delay in physical and mental development of children, etc. [3, 4, 6].

A product of the plant origin "Chophytol" (Lab.Rosa-Phytopharma ma, France) containing the artichoke (Cynara scolymus) leaves extract (ALE) is used in obstetrics for prevention and treatment of PD of various genesis [3, 5, 9]. The results of the previous research show that ALE has expressed the gravidoprotective action under acute ethanol intoxication of rats [1].

The aim of the work was to study the effect of ALE on the postnatal development of infant rats of the 1st generation born by female rats with alcoholic PD.

Materials and Methods

Alcohol-induced PD was initiated with intragastric introduction of 40% ethanol solution in the dose of 4 g/kg to white nonlinear female rats weighting 180-220 g in the fetal phase from the 15th to the 19th days of pregnancy [2]. The artichoke leaves extract was introduced in the medical and preventive regimen from the 14th to the 19th days of the intragastrical gestation in the conditionally therapeutic dose of 50 mg/kg, and the reference medicine Solcoseryl (Valleant pharmaceutical Switzerland GmbH, batch 827509), a natural medicine as well, was introduced in the dose of 0.56 ml/kg, intravenously following the same scheme. Females rats were kept antepartum to study the postnatal development of the 1-st generation. The new-born rats kept under usual conditions characteristic for this type of animals were observed within 30 days.

Viability and the somatosexual development of the 1st generation offspring were estimated by the following parameters: the level of the postnatal lethality, the body weight dynamics on the 1st, 4th, 7th, 14th, 21st and 28th days of observation, pinna detachment and hear-coat covering on the 4th day; eruption of incisors on the 7th day; eyes opening on the 14th day; opening of the vagina and testicles lowering on the 30th day.

Statistical analysis of the data obtained was conducted using the parametric methods (Student’s t-test with Bonferroni adjustment, the significance value p ≤ 0.05) with
The effect of the artichoke leaves extract on lethality of infant rats of the first generation born by female rats with the placental dysfunction caused by ethanol introduction

| Group of animals         | Number of infant rats in total / on the 21\textsuperscript{st} day of observation | Lethality on the day of observation, abs., % | Total lethality, abs., % |

| ALE, 50 mg/kg            | 65/58                                                                              | 1 (1.5 %)                                   | 4 (6.2 %)                | 2 (3.1 %)**              | 7 (10.8 %)**             |
| Solcoseryl, 0.56 ml/kg   | 61/51                                                                              | 2 (3.3 %)                                   | 5 (8.2 %)                | 3 (4.9 %)                | 10 (16.4 %)              |

Notes:
1) \* – statistically significant difference in relation to the animals of the intact control group, \( p \leq 0.05 \);
2) ** – statistically significant difference in relation to the animals of the control pathology group, \( p \leq 0.05 \).

In the group of animals receiving ALE the offspring lethality reduced by an average 2.4 times compared to the control pathology group and was almost the same as in new-borns of healthy females. At the same time the quantity of dead infant rats born by female rats treated with the reference medicine Solcoseryl was only 1.6 times less than in untreated animals. The lethality index of Solcoseryl was 1.5 times greater than the one of the medicine under research.

Starting from the first day of birth the body weight dynamics was registered (Table 2). The initial body weight of infant rats in the group of the intact control on the first day after their birth was 5.96 g. Fast and considerable increase of weight was observed until the 30\textsuperscript{th} day of the experiment. On the background of the prenatal alcoholization of pregnant females the weight of infant rats probably reduced starting from the 1\textsuperscript{st} to the 30\textsuperscript{th} day of the postnatal development compared to the group of healthy animals. Thus, on the 1\textsuperscript{st} and the 4\textsuperscript{th} day of observation it was 1.34 g less; on 7 the 1\textsuperscript{st} day – 1.87 g less, on the 14\textsuperscript{th} day – 4.94 g less, on the 21\textsuperscript{st} day – 9.52 g less, on 30\textsuperscript{th} day – 14.7 g less. Besides, increase of the body weight of infant rats in the control pathology group was slower than in animals of the intact control group.

The body weight of infant rats born by female rats receiving ALE was almost the same as of infant rats of intact animals. Introduction of Solcoseryl also resulted in probable increase of the body weight.

3) *** – statistically significant difference in relation to the animals injected with Solcoseryl, p ≤ 0.05.

in relation to prenatally alcoholized offspring. Compared to Solcoseryl ALE resulted in more significant increase of the body weight from the 1st to 14th day of the experiment. During the further observation till the 30th day of life the difference between the medicines by this index was leveled.

Preventive introduction of ALE resulted positively on the rates of somatosexual development of infant rats. The corresponding indices are given in Table 3.

Unlike healthy animals the physiological signs of development significantly slowed down in infant rats of the control pathology group. Under the action of ALE and Solcoseryl development indices of infant rats achieved physiological norms, and were the same as the indices of the intact animals under research. At the same time Solcoseryl was probably inferior compared to ALE, resulting in reduction of the number of infant rats with delay of indices of somatic (eruption of incisors) and sexual (opening of the vagina) development.

Thus, introduction of alcohol to female rats during pregnancy results in a high index of lethality in new-born rats and delay of their postnatal development. The medicine studied (ALE and Solcoseryl) show the fetoprotective effect under conditions of the perinatal impact on the offspring of females with alcoholic PD.

CONCLUSIONS
1. A positive effect of the artichoke leaves extract and Solcoseryl on the indices of the postnatal development of infant rats of the first generation (lethality, body weight, physical development) has been determined on the model of the placental dysfunction caused by the prenatal ethanol intoxication.
2. The artichoke leaves extract accelerates the somatosexual state of the first generation offspring by such parameters as eruption of incisors, opening of the vagina and has an advantage over the reference medicine Solcoseryl.
3. The results obtained allow to recommend the artichoke leaves extract to be used in complex therapy for preventing the fetal alcoholic syndrome as a complication of the alcoholic placental dysfunction.

Ключові слова: екстракт з листя артишоку польового; солкосерил; алкогольна плацентарна дисфункція; постнатальний розвиток щурів

Проведено експериментальне дослідження впливу екстракту з листя артишоку польового (ЕЛАП) на постнатальний розвиток щурів 1-го покоління, народжених від самок з алкоголю плацентарною дисфункцією (АПД). Встановлено, що ЕЛАП та препарат порівняння солкосерил на тлі введення самкам щурів 40% розчину етанолу в дозі 4 г/кг в лікувально-профілактичному режимі з 14-го по 19-й день гестації сприяли значному зниженню летальності щурів: ЕЛАП в 2,4 рази, а солкосерил в 1,6 рази в порівнянні з нелікованими тваринами. Досліджувані препарати викликали вірогідне зростання маси тіла щурів в порівнянні з контрольними тваринами. З 1-го по 14-й день експерименту прослідковували більш значний приріст маси тіла щурів під впливом ЕЛАП. В подальшому різні в дії препаратів не спостерігавсяся. Введення ЕЛАП та солкосерилу також сприяло корекції патологічних відхилень в постнатальному розвитку щурів. При цих умовах ЕЛАП проявляв більшу активність, ніж солкосерил. Отримані дані дозволяють рекомендувати ЕЛАП з метою використання в акушерстві для превентивної корекції фетального алкоголю синдрому, який розвивається на тлі АПД.

ВЛИЯНИЕ ЭКСТРАКТА А ИЗ ЛИСТЬЕВ АРТИШОКА ПОЛЕВОГО НА ПОСТНАТ АЛЬНОЕ РАЗВИТИЕ ПОТОМСТВА САМОК КРЫС С АЛКОГОЛЬНОЙ ПЛАЦЕНТАРНОЙ ДИСФУНКЦИЕЙ

Ключевые слова: экстракт из листьев артишока полевого; солкосерил; алкогольная плацентарная дисфункция; постнатальное развитие крысят

Проведено экспериментальное исследование влияния экстракта из листьев артишока полевого (ЭЛАП) на постнатальное развитие крысят I-го поколения, родившихся от самок с алкогольной плацентарной дисфункцией (АПД). Установлено, что ЭЛАП и препарат сравнения солкосерил на фоне введения самкам крыс 40% раствора этанола в дозе 4 г/кг в лечебно-профилактическом режиме с 14-го по 19-й день гестации способствовали снижению летальности крысят: ЭЛАП в 2,4 раза, а солкосерил в 1,6 раза по сравнению с нелеченными животными. Изучаемые препараты вызывали достоверное повышение массы тела крысят в сравнении с контрольной патологией. С 1-го по 14-й дни эксперимента прослеживалось более значительное приращение массы тела крысят под влиянием ЭЛАП. В дальнейшем различий в действии препаратов не наблюдалось. Введение ЭЛАП и солкосерил также способствовало коррекции патологических отклонений в постнатальном развитии крысят. При этом ЭЛАП проявлял большую активность, чем солкосерил. Полученные данные позволяют рекомендовать ЭЛАП для применения в акушерстве с целью превентивной коррекции фетального алкогольного синдрома, который развивается на фоне АПД.
