\(d\)-Psicose is a rare sugar present in small quantities in natural products. In a previous study, we showed that \(d\)-psicose suppressed increase in plasma glucose and reduces body fat accumulation in rats. Based on acute toxicity testing in rats, \(d\)-psicose is classified as an ordinary substance (LD50 = 16 g/kg). Elucidating the effects of sub-chronic feeding of \(d\)-psicose in rats is essential before it can be utilized as a physiologically functional food. In this study, male Wistar rats (3 weeks old) were fed diets containing 3% \(d\)-psicose or sucrose for 90 days. The body weight gain and intra-abdominal adipose tissue weight did not differ between the sucrose and the \(d\)-psicose groups. The weights of the liver and kidneys were significantly higher in the \(d\)-psicose group than in the sucrose group. However, no gross pathological findings were evident at dietary doses of 3% \(d\)-psicose or were correlated with hypertrophy of the liver and kidney. In a clinical chemistry analysis, the erythrocyte and leukocyte counts were significantly higher in the \(d\)-psicose group, but that was not considered to be toxicologically significant. Therefore, the present study found no adverse effects of \(d\)-psicose in rats fed a diet containing 3% \(d\)-psicose for 90 days.

Key Words: \(d\)-psicose, sucrose, 90-day oral toxicity, pathological tests, rat

Materials and Methods

All procedures involving animals were approved by the Animal Care Committee of Kagawa University (No.19, 2010). Animals and experimental diets. Twenty male Wistar rats (3 weeks old) were obtained from Japan SLC (Shizuoka, Japan). They were fed CE-2, a commercial rodent diet (CLEA, Tokyo, Japan) and water ad libitum until they were 4 weeks old. They were caged individually at 22 ± 2°C, with light from 08:00 to 20:00 h. The rats were randomly divided into two groups of 10 (sucrose and \(d\)-psicose groups). We adopted sucrose as a control for \(d\)-psicose because sucrose is a very popular sweet carbohydrate and is used in many studies as a control saccharide. The experimental diets were 3% sucrose or \(d\)-psicose added to CE-2. The amount of test carbohydrates (3%) was determined with reference to previous studies concerning \(d\)-psicose (13) or sucrose, which has an LD50 that is the same as that of \(d\)-psicose (16 g/kg weight) (17,18). Each group of rats was given free access to food and water for 90 days. \(d\)-Psicose, which was made from high fructose corn syrup by the alkaline isomerization method, was donated by Rare Sugar Production Thecnical Research Laboratories, LLC (Kagawa, Japan). The high fructose corn syrup was used as a raw material was supplied by Matsutani Chemical Industry, Co., Ltd. (Hyogo, Japan). Sucrose was purchased from Wako Pure Chem. Ind. (Osaka, Japan).

Experimental design. After 90 days of feeding, rats in each group were fasted for 4.5 h beginning at 06:00 h, and then were anesthetized via the intraperitoneal administration of sodium pentobarbital. Blood was collected from the abdominal aorta for clinical hematological analysis and to obtain serum for the chemical analysis. The rats were allowed to exsanguinate. The brain, heart, lungs, liver, pancreas, kidneys, adrenal glands, spleen, testicles, intra-abdominal adipose tissues (epididymal, perirenal and mesenteric) and muscle tissues (soleus, gastrocnemius and plantarius) were quickly removed and weighed. Parts of the liver, kidneys and small intestine (about 5 mm of the end of the jejunum) were examined.
were preserved in 10% neutral buffered formalin for histopathological examinations. The stomach, small intestine, large intestine, and cecum were also quickly removed and weighed. In addition, the small and large intestine length, surface area and cecal content weight were measured.

**Analysis.** The following hematomatological and clinical chemistry parameters were evaluated WBC, RBC, Hb, Ht, MCV, MCH, MCHC, PLT, TP, A/G, ALUB, GLO, AST, UA, BUN, CREA, Ca, Fe, CHO, TG, GLU, and FFA. The hematomatological and chemical analyses were performed by Shikokuchuken Co., Ltd. (Kagawa, Japan). The histopathological examinations were performed by Shikoku Cytopathology Center Co., Ltd. (Kagawa, Japan). The fixed tissue samples from the liver, kidney and small intestine were embedded in paraffin and cut with a microtome set at a thickness of 5–6 µm. The tissue sections were stained with hematoxylin and eosin (HE) and examined with a light microscope. Next, the histopathological findings in each rat were subjectively quantified as follows: −, 0; ±, 1; +, 2; ++, 3; ++++, 4.

**Statistical analysis.** All values were expressed as the mean ± SD. The statistical analysis of the differences between the sucrose and D-psicose groups was performed using Student’s t test. Statistical significance was set at p value of <0.05. All analyses were performed with a commercially available statistical software package (Excel Statistics 2008, SSRI, Co., Ltd.).

**Results**

**Body and tissue weights, food intake and digestive tract size.** Results for the body and tissue weights, food intake and digestive tract size in rats fed the two substances for 90 days are presented in Table 1. The final body weight, weight gain and food intake did not differ between the sucrose group and the D-psicose group. Rats actually ingested 1.67 g/kg body weight per day D-psicose or 1.65 g/kg body weight per day of sucrose (mean values for 90 days). The mean liver and kidney weights were significantly higher in the D-psicose group than in the sucrose group, but no differences were observed in any other tissues.

**Table 1. Body weight, food intake and tissue size**

| Groups         | Sucrose | D-psicose |
|----------------|---------|-----------|
| Initial weight (g) | 59 ± 4  | 59 ± 4    |
| Final weight (g)     | 343 ± 24| 346 ± 29  |
| Weight gain (g)       | 284 ± 20| 287 ± 27  |
| Food intake (g/day)   | 18.9 ± 0.6| 19.3 ± 1.1|
| Tissue weights       |         |           |
| Brain (g)            | 1.73 ± 0.21| 1.77 ± 0.16|
| Heart (g)            | 0.80 ± 0.05| 0.79 ± 0.04|
| Lungs (g)            | 0.99 ± 0.04| 0.99 ± 0.07|
| Liver (g)            | 8.98 ± 0.92| 10.1 ± 1.26* |
| Pancreas (g)         | 0.43 ± 0.07| 0.43 ± 0.09 |

| Adrenals (g)         | 0.05 ± 0.01| 0.05 ± 0.01 |
| Spleen (g)           | 0.70 ± 0.08| 0.69 ± 0.08 |
| Testicles (g)        | 2.98 ± 0.09| 3.01 ± 0.16 |
| Intra-adipose tissues* (g) | 21.0 ± 3.89| 19.9 ± 2.53 |
| Muscle tissues* (g)  | 3.95 ± 0.25| 3.88 ± 0.25 |
| Intestinal tracts size |       |           |
| Small intestine weight (g) | 5.13 ± 0.60| 5.21 ± 0.49 |
| length (m)           | 1.02 ± 0.06| 1.04 ± 0.04 |
| Large intestine weight (g) | 1.07 ± 0.14| 1.19 ± 0.16 |
| length (×10⁻² m)     | 18.4 ± 1.97| 19.6 ± 1.90 |
| Cecum content (g)    | 3.80 ± 1.07| 4.13 ± 0.57 |
| weight (g)           | 0.75 ± 0.12| 0.78 ± 0.10 |
| surface area (×10¹⁻ mm²) | 3.60 ± 0.31| 3.54 ± 0.15 |

Values are means ± SD for 10 rats. *Significant difference from the Sucrose group (p<0.05, Student’s t test). Total weight of epididymal, perirenal and mesenteric adipose tissues. Total weight of soleus, gastrocnemius and plantaris muscles.

In the present study, rats actually ingested 1.67 g/kg body weight per day of D-psicose or 1.65 g/kg body weight per day of sucrose. The body weight gain and intra-abdominal adipose tissue weight in rats did not differ between the two dietary groups.

We previously reported that D-psicose supplements suppress
accumulation more effectively than sucrose. 

**Table 2. Serum chemical and blood hematological test results**

| Groups     | Sucrose | D-Psicose |
|------------|---------|-----------|

| TG (mg/100 ml) | 42.2 ± 21.9 | 68.1 ± 28.0 ± |
| GLU (mg/100 ml) | 142 ± 17 | 173 ± 18 ± |
| FFA (mEq/100 ml) | 0.67 ± 0.15 | 0.69 ± 0.10 ± |
| Blood      |         |           |
| WBC (10³/μl) | 30.9 ± 5.4 | 44.4 ± 3.7* |
| RBC (10³/μl) | 896 ± 27 | 936 ± 28* |
| Hb (g/100 ml) | 15.3 ± 0.3 | 15.3 ± 0.3 ± |
| Ht (%)      | 45.6 ± 0.8 | 45.0 ± 0.9 ± |
| MCV (fl)    | 51.0 ± 1.4 | 48.2 ± 0.8* |
| MCH (pg)    | 17.1 ± 0.4 | 16.3 ± 0.2* |
| MCHC (%)    | 33.5 ± 0.4 | 33.9 ± 0.4* |
| PLT (10³/μl) | 64.7 ± 6.3 | 71.8 ± 6.3* |

Values are means ± SD for 10 rats. *Significant difference from the Sucroce group (p<0.05, Student's t test).

hepatic lipogenic enzyme activity and reduce intra-abdominal fat accumulation more effectively than α-glucose or α-fructose supplements in rats. In addition, we found that D-psicose is a sweet monosaccharide that provides no energy to growing rats. The present findings did not support our previous results. However, another study demonstrated that rats fed a 3% D-psicose diet for 12 months did not differ in most of the parameters from rats fed 3% sucrose, which indicates that D-psicose did not inhibit rat growth. Therefore, low dietary levels (3% of diet or less) of D-psicose over an extended period primarily affected fat accumulation, with either no effects or only minimal effects on other organs.

In a previous short-term toxicity test in rats, we showed that the feeding of diets with extremely high levels of D-psicose appeared to be harmful to the intestinal tract. Moreover, we previously reported that the cecal weight, cecal surface area and cecal content weight increased with increases of D-psicose in the diet (above 10%). D-Psicose is partly absorbed in the digestive tract and is excreted into the urine and feces. However, it is also fermented in the cecum by intestinal microflora, producing short-chain fatty acids as soluble dietary fiber. In this study, no adverse effects on the intestinal tract were seen when the rats were fed 3% D-psicose in the diet. Therefore, 3% D-psicose in the diet does not appear to be harmful to the intestinal tract.

Dietary D-psicose increased the weights of the animal’s liver (12% larger than the sucrose group) and kidneys (14% larger). This finding agrees with our previous studies. The serum level of AST is used as an index of hepatic damage. These values in this study did not differ between the D-psicose and sucrose groups. In addition, histopathological observations of the liver and kidneys revealed no abnormalities due to the ingestion of D-psicose. Liver enlargement occurs in animals and humans under a variety of conditions, with different consequences for health. For example, it can be the result of a physiological adaptation to an enhanced workload or metabolic demand, metabolic abnormalities, toxicity, an inflammatory process, or due to proliferative disease. Bar et al. found that D-tagatose, another rare sugar, increased liver glycogen deposition and relative liver weights in non-fasting rats at dietary levels of 5–20%. D-Tagatose is an incompletely absorbed ketohexose that has potential as an energy-reduced alternative sweetener. They concluded that the liver enlargement seen in response to the consumption of D-tagatose was a physiological response to the treatment-induced increase in glycogen deposition. We previously found that D-psicose treatment induced an increase in glycogen deposition. In addition, it was reported that D-psicose could increase the glucokinase activity by enhancing the translocation of glucokinase from the nucleus to the cytoplasm in the liver of diabetic rats. However, it is unknown whether these mechanisms of liver enlargement induced by D-psicose and D-tagatose are the same.

Glycogen deposition and liver enlargement (increased relative

**Table 3. Histopathological observations of liver, kidney and small intestine**

| Groups     | Sucrose | D-Psicose |
|------------|---------|-----------|
| Liver      |         |           |

liver weights) were also seen in rats fed diets with high levels of various other saccharides.\(^{28-30}\) It was hypothesized that the formation of phosphorylated metabolites plays a crucial role in this process, either by activating glucokinase or by changing the intracellular concentrations of phosphate compounds.\(^{31}\) It is possible that D-psicose, of which about 50% is absorbed,\(^{31}\) is more active than D-fructose in promoting glycogen deposition. The slower degradation of psicose-1-phosphate may account for this phenomenon.

In the hematological analysis performed as part of this study, dietary D-psicose significantly increased the WBC, RBC and PLT values compared to sucrose, and significantly decreased the MCV and MCH values. However, these values remained within the normal range, indicating that there was no overt D-psicose toxicity.

In conclusion, the present study evaluated the effects of 90-day 3% D-psicose administration to rats, and found that there were to be increases in the liver and kidney weights, with no gross pathological findings associated with this hypertrophy. The hematological and chemical values were not suggestive of any overt D-psicose toxicity. Overall, no adverse effects were seen at this low dose level of D-psicose in the diet.

Acknowledgments

We would like to thank Dr. Koji Kondo, Rare Sugar Production Thechnical Research Laboratories, LLC (Kagawa, Japan) for donating D-psicose. This work was supported by the Regional Innovation Creation R&D Programs, Ministry of Economy, Trade and Industry, Japan.
