BE-PIGS: a base-editing tool with deaminases inlaid into Cas9 PI domain significantly expanded the editing scope

To the Editor,

The discovery of base-editing tools sheds new light on both basic biomedical research and clinical therapeutics. Although showing profound performance in a wide range of applications, current base editors have their limitations. In particular, the narrow editing windows of these base editors have significantly limited their targetable sites. In current base editors, the most frequent limitation is that inlaying deaminases directly into the PI or RuvC3 domains (Fig.1a), that is, site 1054 (between G1054 and E1055) and site 1246 (between G1246 and S1247), which we named BE-PIGS showed a slightly low editing efficiency than BE3 and BE4 in the cytosines (Cs) located within the editing window of BE3 or BE4 (positions 4–8, numbering the PAM as positions 21–23), while performing much higher editing in Cs downstream of this window (Fig. 1e), indicating that the BE-PIGS base editor might have a wider editing window than that of BE3 or BE4. To further confirm this, we characterized the editing window of BE-PIGS with additional targets that possess multiple Cs. As shown in Fig. 1f, BE-PIGS achieved considerable editing in Cs that were only six bases away from the PAM (position 14). Together, these data demonstrated that inlaying APOBEC1 into the PI domain significantly increased the editing width (Fig. 1g), ranging from position 4 to position 14, with the maximum editing occurring around position 7–13 (Fig. 1g). This finding was in consistent with a recent publication in which tethering deaminase to the PI domain of a circular permuted Cas9 also expanded the editing window.

Then, we examined the effects of the length of linker, connecting the deaminase and the Cas9 PI domain on the editing efficiency and window. We first shortened the N-terminal linker, keeping the C-terminal linker unchanged. We showed that shortening the N-terminal linker from 16 aa to 8 aa or 3 aa generally reduced the editing efficiency in all targetable Cs, but did not obviously change the width of the editing window. Similar effects were also observed when the C-terminal linker was shortened from 32 aa to 20 aa or 5 aa (Fig. S3).

Recently, a BE system based on Sun-tag (GCN4/scFv) mediated linkage of deaminase and Cas9 was shown to expand the editing window (BE-PLUS). To test whether the Sun-tag system is also feasible for and further expands the editing window of BE-PIGS, we inserted six copies of GCN4 helices into the PIGS site to form PIGS-GCN4. We showed that transfections of this construct together with scFv tagged APOBEC1 yielded a slight reduction in editing in a set of target sites, and did not further enlarge the editing window (Fig. S4).

Previous studies have revealed that truncating the spacers within SpyCas9 sgRNAs reduced off-target effects and altered the editing window in SpyCas9 derived base editors. We therefore tested the effects of sgRNA truncation on our base-editing system. We truncated the spacers within a set of sgRNAs from 20 to 17 or 15 nt. In one out of the three target sites tested, the truncated guide RNA led to a narrowed editing window (Fig. S5). However, this phenomenon was not observed in the rest target sites.
suggesting that the effects of sgRNA truncation on the editing window are protospacer specific. In summary, we generated a novel base-editing system by inlaying deaminase into the PI domain of the SpyCas9 protein, BE-PIGS. We showed that internally inlayed deaminase or GCN4 tag retained their ability to induce base substitution but did not destroy Cas9 activity for target recognition. BE-PIGS has a much wider editing window than BE3 or BE4, which is particularly useful in cases where wide editing ranges are required or targeted bases are extremely close to the PAM.
