Abstract

A topological version of four-dimensional (Euclidean) Einstein gravity which we propose regards anti-self-dual 2-forms and an anti-self-dual part of the frame connections as fundamental fields. The theory describes the moduli spaces of conformally self-dual Einstein manifolds for a cosmological constant \( \Lambda \neq 0 \) case and Einstein-Kählerian manifold with the vanishing real first Chern class for \( \Lambda = 0 \). In the \( \Lambda \neq 0 \) case, we evaluate the index of the elliptic complex associated with the moduli space and calculate the partition function. We also clarify the moduli space and its dimension for \( \Lambda = 0 \) which are related to the Plebansky’s heavenly equations.

*On leave of absence from Tokyo Institute of Technology after April 1994.
I. INTRODUCTION

Recently a number of noteworthy connections have been revealed between a class of field theories called topological quantum field theories on one hand, and the mathematical advances in the topology and geometry of low dimensional manifolds on the other. The study of these relations has been introduced by Schwarz\cite{1} and Witten\cite{2}. Topological quantum field theories are constructed by fields, symmetries and equations.

One concept that lies in the topological quantum field theory is the realization of the moduli spaces. The moduli space is defined as the equivalent set of the solutions of the fields for the equations associated to the symmetries of topological quantum theories. These theories can be described by the moduli spaces and are characterized by their topological and geometrical invariants which depend only on moduli parameters. There may be various topological quantum field theories which describe the same moduli space. The prime interest of these theories is these invariants, which are computable by standard techniques in quantum field theories.

Some gravitational versions of topological quantum field theories are also given by Witten\cite{3,4}. The two-dimensional gravity models are of importance and promise new insight into the string theory \cite{4}. He conjectured that certain series of critical points in the matrix model approach (i.e. the dynamical simplicial decomposition of Riemannian surfaces) is equivalent to the two-dimensional topological gravity. In fact, Kontsevich used the intersection theory \cite{5} to support the conjecture. This result is important to know the non-perturbative effect of the string theory.

Since the work of Witten, there have been several attempts to construct four-dimensional topological gravity theories over different kinds of the gravitational moduli spaces \cite{3-11}. For example, the moduli space of the conformally self-dual gravitational instantons was investigated in detail by Perry and Teo \cite{6}.

In previous papers \cite{12,13} we proposed a four-dimensional topological gravity model. This model contains two types of topological field theories; Witten-type topological field theory in the cosmological constant $\Lambda \neq 0$ case and Schwarz-type topological field theory in the $\Lambda = 0$ case. They are
obtained by modifying a chiral formulation of Einstein gravity developed by Capovilla et al. [14]. In these theories three quaternionic Kähler forms and the anti-self-dual part of the frame connections of the principal bundle $P_{SO(4)}$ are used as fundamental fields. The advantages of using these fields are that the treatment analogous to that of Yang-Mills field is possible and that the moduli space can be easily defined in terms of them efficiently.

In the $\Lambda \neq 0$ case, the moduli space is the set of the equivalence class of the fields defining the Einstein conformally self-dual Riemannian manifolds. This moduli space is up to orientation, identical with the one considered by Torre [7]. In his paper the dimension of the moduli space is found to be zero when the cosmological constant is positive, and the result is true also in our case. In the $\Lambda = 0$ case, the moduli spaces are those of Einstein-Kählerian manifolds with vanishing real first Chern class.

The purpose of our attempt is to investigate the four-dimensional gravitational instantons and derive the topological invariants such as the partition function and observables. We explore the relation between the simplicial decomposition of four-dimensional manifolds and the four-dimensional topological gravity.

We can regard the $\Lambda \neq 0$ case as a simple example of a gravitational analogue of the Donaldson theory and expect that we can calculate some topological invariants such as the partition function in four dimensions.

On the contrary, the $\Lambda = 0$ case is a BF-type topological gravity model. The partition function of the abelian BF-theory is represented by the Ray-Singer torsion [16]. Thus it is interesting to confirm whether our partition function in the $\Lambda = 0$ can be related to the Ray-Singer torsion or not.

Another aspect of the $\Lambda = 0$ case is that it provides the self-dual equations of Riemannian curvature 2-form. There have been discovered various kinds of non-compact gravitational instantons (i.e. ALE [17] or ALF [18]) which satisfy these equations. In this paper we will treat the compact manifolds only. In the near future we will extend our investigation to the non-compact case.

The plan of the paper is as follows. In section II, we present a classical action, fields content and equations of motion, and define the moduli spaces
in our theory. We explain each case separately to avoid the confusion. In section III, we formulate the BRST transformations of our model. In section IV, we mention the dimension of the moduli space and zero modes which appear in the partition function in the $\Lambda \neq 0$ case. In section V, the gauge fixing conditions are introduced and the partition function is derived in the $\Lambda \neq 0$ case. In section VI, we explain the dimension of the moduli space in the $\Lambda = 0$ case. The section VII is devoted to discussion.
II. TOPOLOGICAL 2-FORM GRAVITY

We adopted the following action suggested by Capovilla et al. [14] and Horowitz [19] for our topological gravity model on a four-dimensional manifold $M_4$.

$$S_{TG} = \frac{1}{\alpha} \int_{M_4} \left[ \Sigma^k \wedge F_k - \frac{\Lambda}{24} \Sigma^k \wedge \Sigma_k \right]$$  \hspace{1em}  (k = 1, 2, 3),  

where $\alpha$ is a dimensionless parameter and $\Lambda$ is a cosmological constant (as we will see later that it will appear in Einstein equation $R_{\mu\nu} = \Lambda g_{\mu\nu}$ with $\mu, \nu = \{0, \cdots, 3\}$).

We start with fundamental fields, a trio of su(2) valued 2-forms $\Sigma^k$ and a su(2) valued 1-form $\omega^k = \omega^k_{\mu} dx^\mu$. $F^k$ denotes the su(2) valued 2-form with $F^k = F^k_{\mu\nu} dx^\mu \wedge dx^\nu \equiv d\omega^k + (\omega \times \omega)^k = d\omega^k + \epsilon^{ijk} \omega^i \wedge \omega^j$ ($\epsilon^{ijk}$ is the structure constant of $SU(2)$). Varying the action with respect to each of fields $\Sigma^k$ and $\omega^k$, we obtain the equations of motion:

$$\begin{align*}
\Lambda &\neq 0 ; \ F^k - \frac{\Lambda}{12} \Sigma^k = 0 , \ D\Sigma^k = 0 , \\
\Lambda & = 0 ; \ F^k = 0 , \ D\Sigma^k = 0 ,
\end{align*}$$  \hspace{1em}  (2a) \hspace{1em}  (2b)

where $D\Sigma^k = d\Sigma^k + 2(\omega \times \Sigma)^k$.

In this paper, we take $\alpha \to 0$ limit in Eq. (1) to make the contribution from Eq. (2a) or Eq. (2b) dominant in our theory. We are interested in the moduli spaces which are defined by Eq. (2a) or Eq. (2b) and the gauge fixing conditions which we will explain later. This treatment is similar to that of the large $k$-limit of the Chern-Simons theory [15].

For $\Lambda \neq 0$, one of equations of motion $D\Sigma^k = 0$ can be derived by $F^k - \frac{\Lambda}{12} \Sigma^k = 0$ and Bianchi Identity $DF^k = 0$. Eliminating $\Sigma^k$ from the action by using Eq. (2a) we obtain the effective action proportional to the second Chern number $\int F^k \wedge F_k$, which is the classical action of the TYMT (the Donaldson theory) for the SU(2) gauge group [20]. Thus the theory reduces to a Witten-type topological gravity model on-shell. On the other hand, for the $\Lambda = 0$ case, the action describes a Schwarz-type (BF-type) topological field theory [16] [19].
We suppose the following conditions for the action.

Postulate 1a for $M_4$ with $\Lambda \neq 0$:

$M_4$ is a four-dimensional oriented Riemannian manifold.

Postulate 1b for $M_4$ with $\Lambda = 0$:

$M_4$ is a four-dimensional oriented Riemannian manifold and has an almost complex structure with its real first Chern class $c_1(M_4)_R = 0$.

Postulate 2 for the field $\omega^k$:

We consider the principal bundle $P_{SO(4)}$ of oriented orthonormal frames over $M_4$ with the structure group $SO(4)$. This bundle is associated by the tangent bundle with a metric $\tilde{g}_{\mu\nu} = \tilde{e}_a^\mu \tilde{e}_b^\nu \delta_{ab}$, where $a, b = \{0, \ldots, 3\}$. $\tilde{e}^a = \tilde{e}_a^\mu dx^\mu$ is a vierbein (a section of $\text{End}(TM_4) = T^*M_4 \otimes TM_4$ with the assumption of $\det(\tilde{e}) \neq 0$). We suppose that the field $\omega^k_\mu$ denotes an anti-self-dual part of the frame connections (a connection of $P_{SU(2)}$ which comes from $P_{SO(4)} \sim P_{SU(2)} + P_{SU(2)}$). $\omega^k$ is related to anti-self-dual part of $so(4)$ valued 1-form connection $(-)\omega^{ab}_\mu$ via $\eta^k_{ab}$:

$$(-)\omega^{ab}_\mu(\tilde{e}) = \eta^k_{ab} \omega^k_\mu(\tilde{e}),$$  \hfill (3)

where $\eta^k_{ab}$ is an anti-self-dual constant called the t’Hooft’s $\eta$ symbols [21]. $\eta^k_{ab} = \epsilon_k^{abc} \epsilon^b_c + \frac{1}{2} \epsilon_{kij} \epsilon^{ijab}$ with $i, j, k = \{1, 2, 3\}$. Some useful properties of $\eta^k_{ab}$ are given in Appendix I. A point to notice is that $M_4$ is an oriented Kählerian manifold with $c_1(M_4)_R = 0$ from the postulate 1b. Thus at least the reduction of the structure group $SO(4) \rightarrow U(2)$ is possible for the $\Lambda = 0$ case (see Ref. 21 and Fig. 1).

Furthermore we assume the parallelizability of $\tilde{e}^a_\nu$ with the Levi-Civita connection $\Gamma^a_{\mu\nu}$ and the frame connection $\omega^{ab}_\mu$ defined by $\tilde{e}^a_\mu$. This is a sufficient condition for the metricity of $\tilde{g}_{\mu\nu}$ ($\nabla_\tau \tilde{g}_{\mu\nu} = \partial_\tau \tilde{g}_{\mu\nu} - \Gamma^a_{\mu\tau} \tilde{g}_{a\nu} - \Gamma^a_{\nu\tau} \tilde{g}_{a\mu} = 0$); $\nabla_\nu(\tilde{e}^a_\mu) = \partial_\nu \tilde{e}^a_\mu + \Gamma^a_{\sigma\nu}(\tilde{e}) \tilde{e}_a^\sigma - \omega^{b}_{a\nu}(\tilde{e}) \tilde{e}_b^\mu = 0$. \hfill (4)

From this equation, the relation between Riemannian tensor and the curvature tensor $F^k$ is given by

$$(-) R^\rho_{\mu\nu\tau} (\tilde{g}(\tilde{e})) = 4 F^{ab}_{\mu\nu} \tilde{e}_a^\rho \tilde{e}_b^\tau = 4 F^{k}_{\mu\nu} \eta^a_b \eta^b_a,$$  \hfill (5)

where $R_{\mu\nu\rho\tau} = (+) R_{\mu\nu\rho\tau} + (-) R_{\mu\nu\rho\tau}$. It is well known that the Riemann curvature tensors over $M_4$ are written in block diagonal form of $6 \times 6$ matrix
\[
R = \begin{pmatrix}
(+) R_{\mu\nu\rho\tau} \\
(-) R_{\mu\nu\rho\tau}
\end{pmatrix} = \begin{pmatrix}
(+) W_{\mu\nu\rho\tau} + (+) S_{\mu\nu\rho\tau}, \\
(+) t K_{\mu\nu\rho\tau}, \\
(-) W_{\mu\nu\rho\tau} + (-) S_{\mu\nu\rho\tau}
\end{pmatrix}.
\]

\((+) W_{\mu\nu\rho\tau}\) is the self-dual part of the Weyl tensor and \((-) W_{\mu\nu\rho\tau}\) is its anti-self-dual part. \((+)^{\rho}_{\mu} \delta^{\tau}_{\nu} \pm \frac{1}{2} \epsilon^{\rho}_{\mu\nu\tau} R\) and \(K_{\mu\nu\rho\tau} \propto \delta^{\rho}_{\mu} \Phi^{\nu\tau}\), where \(\Phi^{\nu\tau}\) is the trace free part of the Ricci tensor and \(R\) is the scalar curvature.

**Postulate 3**  for \(\Sigma^k\) field:

\(\{\Sigma^k\}\) are a trio of \(su(2)\) valued 2-forms. We suppose that the index \(k\) of \(\Sigma^k\) and \(\omega^k\) denotes the anti-self-dual part of \(so(4)\) index. Namely \(su(2)\) is a Lie algebra of \(SU(2)_L\) which comes from \(SPIN(4) = SU(2)_L \times SU(2)_R\) (the double covering group of \(SO(4)\)).

Our stance for this model is that the fundamental variables are not \(\tilde{e}^a\) but \(\omega^k\) and \(\Sigma^k\). We seek the solutions of them which satisfy the above postulates, equations of motion and the gauge fixing conditions. These conditions specify the manifolds concerning to our model and the property of metrics or almost complex structures on them.

We now turn to the gauge fixing conditions which we set to restrict five degrees of the freedom of \(\Sigma^k\). In this topological model, there exists a symmetry generated by a parameter 1-form \(\theta^k\) in addition to the \(SU(2)_L\) (with a \(su(2)\) valued 0-form \(v^k\)) and diffeomorphism (with a vector field \(\xi^\mu\)) symmetries,

\[
\begin{align*}
\delta \omega^k = & D_\tau v^k + (\mathcal{L}_\xi \omega^k)_\tau + \frac{\Lambda}{12} \theta^k \\
\delta \Sigma^k = & 2(\Sigma_{\mu\nu} \times v)^k + (\mathcal{L}_\xi \Sigma^k)_{\mu\nu} + D_\mu \theta^k,
\end{align*}
\]

The \(\theta^k\)-symmetry is regarded as a ‘restricted’ topological symmetry which preserves the equations of motion (2a) or (2b). With the appearance of the \(\theta^k\)-symmetry, the theory turns out to be on-shell reducible in the sense that the transformation laws (3) are invariant under

\[
\begin{align*}
\delta v^k = & -\frac{\Lambda}{12} \epsilon^k + \rho^\sigma \omega^k_\sigma \\
\delta \theta^k = & D_\mu \epsilon^k + 2 \rho^\nu \Sigma^k_{\nu\mu} \\
\delta \xi^\mu = & -\rho^\mu,
\end{align*}
\]

as long as the equations of motion are satisfied. The transformations with parameters \(\epsilon^k\) and \(\rho^\mu\) correspond to redundant \(SU(2)\) and redundant diffeomorphism, respectively.
Our strategy to construct a topological quantum field theory is to consider the following five equations as gauge fixing conditions for the $\theta^k$-symmetry (except for the redundant part of the symmetry).

Postulate 4 for the gauge fixing conditions for the $\theta^k$-symmetry:

\[ t.f. \Sigma^i \wedge \Sigma^j \equiv \Sigma^i \wedge \Sigma^j - \frac{1}{3} \delta_{ij} \Sigma^k \wedge \Sigma_k = 0. \] (8)

These constraints were imposed in the original 2-form Einstein gravity \[14\] and are necessary and sufficient conditions that $\Sigma^k$ comes from a vierbein $e^a = e^a_\mu dx^\mu$.

\[ \Sigma^k(e) = -\eta^{k}_{ab}e^a \wedge e^b. \] (9)

(We should remark that $e^a$ is independent of $\tilde{e}^a$ in this stage). \{$\Sigma^k(e)$\} have 13 degrees of freedom. The Riemannian metric $g_{\mu\nu} = e^a_\mu e^b_\nu \eta_{ab}$ can be expressed in terms of $\Sigma^k(e)$;

\[ g^{\frac{1}{2}}g_{\mu\nu} = -\frac{1}{12} \epsilon^{\alpha\beta\gamma\delta} \Sigma_{\mu\alpha k}(\Sigma_{\beta\gamma \times \Sigma_{\delta\nu k})}^k, \quad g \equiv \det(g_{\mu\nu}). \] (10)

Such a 2-form $\Sigma^k(e)$ is anti-self-dual with respect to world indices $\mu, \nu$ by the Hodge dual operation $*g(\Sigma(e))$ which is defined via Eq. (10). (But it does not necessarily mean that $\Sigma^k(e)$ belongs to $su(2)$ valued anti-self-dual 2-forms part only because these eigenspaces of the dual operation vary as the deformations of $\Sigma^k$ and $g_{\mu\nu}(\Sigma)$.)

The set of equations (2a) or (2b) and (8) arose before as an ansatz within the framework of 2-form Einstein gravity with the cosmological constant \[14\] \[23\]. We consider them to be gravitational instanton equations. The degrees of the freedom of the fundamental fields are completely fixed by the above conditions (see Table 1).

We also assume the parallelizability of $e^a_\nu$ with the Levi-Civita connection and the frame connection defined by $e^a_\nu$ as before. The equation

\[ \nabla(e)_{\mu} \nabla(e)_{\nu} \Sigma^k_{\mu\nu} = 0, \] which comes from Eq. (9) and this parallelizability yield the following relation between the curvature tensor $F^k(e)$ and Riemannian curvature tensor;

\[ (-)^{R_{\mu\nu\rho\tau}(e)} = 4F_{\mu\nu}^k(e)\Sigma_{\rho\tau k}(e). \] (11)

Now we will explain what kinds of Riemannian tensors are derived from the solutions of \{$\Sigma^k$\} which satisfy Eqs. (8), (11) and (2a) for $\Lambda \neq 0$ (or Eqs.
(8), (11) and (2b) for \( \Lambda = 0 \) and show the definitions of each moduli space.

(a) \( \Lambda \neq 0 \) case:

Using the property of Riemannian manifold such as torsion tensor \( T^a \propto D(e) \) and Eq. (9) we obtain \( D(e)\Sigma^k(e) = 0 \). Comparing this with \( D(\tilde{e})\Sigma^k(e) = 0 \), we have:

\[
\omega^k(\tilde{e}) = \omega^k(e), \quad F_{\mu\nu}^k(\tilde{e}) = F_{\mu\nu}^k(e). \tag{12}
\]

Thus we obtain that

\[
t.f. F^i(e) \wedge F^j(e) = t.f. F^i(\tilde{e}) \wedge F^j(\tilde{e}) = 0. \tag{13}
\]

which leads to \( \Sigma^k(e) = \Sigma^k(\tilde{e}) \). (Note that \( \Sigma^k(e) = \Sigma^k(\tilde{e}) \) is not a sufficient condition for

By substituting \( F^k(e) = F^k(\tilde{e}) = \Lambda \Sigma^k(e) \) into Eq. (11)

\[
(-)R_{\mu\nu\rho\tau}(\Sigma(e)) = (-)S_{\mu\nu\rho\tau}(\Sigma(e)). \tag{14}
\]

Namely \( M_4 \) becomes a conformally self-dual Einstein manifold.

\[
(\Lambda \neq 0; \quad R_{\mu\nu}(e) = \Lambda g_{\mu\nu}(e) \quad \text{and} \quad (-)W_{\mu\nu\rho\tau}(e) = 0. \tag{15}
\]

The moduli space in this case is defined by \( \omega^k \) only;

\[
\mathcal{M}(\omega) = \{ \omega^k \mid \omega^k \in su(2) \otimes \Lambda^1, \quad t.f. F^i \wedge F^j = 0 \}/\{SU(2) \times diffeo.\}. \tag{16}
\]

It corresponds to the moduli space of the conformally self-dual Einstein metrics because these metrics are represented by \( \omega^k \) via Eqs. (2a) and (10). If we consider only compact Einstein conformally self-dual Riemannian manifolds with \( R > 0 \) (\( \Lambda > 0 \)), then \( M_4 \) is either isometric to \( S^4 \), or to \( CP^2 \), with their standard metrics from the theorem given by Hitchin [24]. So the solution \( \Sigma^k(e) \) determines the standard metric on \( S^4 \) or the Fubini-Study metric on \( CP^2 \) for \( \Lambda > 0 \).

(b) \( \Lambda = 0 \) case:

From Eqs. (5) and (21), the Riemannian tensor defined by \( \tilde{e}^a \) is self-dual;

\[
(-)R_{\mu\nu\rho\tau}(\tilde{e}) = 0 \tag{17}
\]
so \((M_4, g)\) is a Ricci-flat Kählerian manifolds. The following theorem gives the characterization of Ricci-flat Kählerian manifolds:

Theorem (Hitchin [24])

Let \(M_4\) be a compact connected oriented Riemannian manifold. If \(M_4\) is Ricci-flat and \((+)^W_{\mu\nu\tau\rho} = 0\), then \((M_4, g)\) is one of the following four cases:

1. \((M_4, g)\) is flat, i.e. is covered by a flat 4-torus
2. \((M_4, g)\) is a Kähler-Einstein K3-surface \((\pi_1 = 1)\)
3. \((M_4, g)\) is a Kähler-Einstein Enriques surface \((\pi_1 = \mathbb{Z}_2)\)
4. \((M_4, g)\) is the quotient of a Kähler-Einstein Enriques surface by a free anti-holomorphic isometric involution \((\pi_1 = \mathbb{Z}_2 \times \mathbb{Z}_2)\).

(We should better take the opposite orientation of \(M_4\) and replace \(\eta_{ab}^k\) by self-dual notation \(\bar{\eta}_{ab}^k\) for the \(\Lambda = 0\) case so that \((+)^R_{\mu\nu\tau\rho}(e) = 0\) and Einstein-Kähler forms \(\{\Sigma\}\) belong to self-dual \((1,1)\) form.)

The relation between the vanishing covariant derivative with a Levi-Civita connection and the holonomy group \(\text{Hol}(g)\) asserts that \(\text{Hol}(g) \subseteq U(2)\) for Kählerian manifolds with the complex dimension two. These compact Kählerian manifolds with \(c_1(M_4)_R = 0\) are exactly the compact complex manifolds admitting a Kähler metric with zero Ricci form (or equivalently the compact complex manifolds with restricted holonomy group contained in the special unitary group). We now investigate the properties of the metrics or the complex structures defined by \(\Sigma^k(e)\) on these manifolds. We divide these manifolds into two groups.

case b-1 (when the canonical line bundle \(K\) is trivial):

\(M_4\) is a K3-surface or a four-torus \(T^4\).

On these two manifolds, the following reductions of \(P_{U(2)}\) are possible due to the fact that the canonical line bundles \(K\) over them are trivial. Actually, the restricted holonomy group \(\text{Hol}_0(g)\) reduces to the identity exactly when a metric is flat for \(T^4\). Though \(T^4\) is not a simply-connected, \(\text{Hol}(g) = \text{Hol}_0(g)\) happens. Therefore the reduction \(P_{U(2)} \to P_f\) is possible and all frame connections can be gauged away when metric is flat [24]. A K3-surface is, by definition, a compact simply-connected complex surface with trivial canonical line bundle \(K\) and \(b_1 = 0\). For a Calabi-Yau metric (a
Kähler-Einstein metric) $Hol(g) = Hol_0(g) \subseteq SU(2)_R \cong SP(1)$. Thus $SU(2)_L$ connections $\{\omega^k(\tilde{e})\}$ can be gauged away.

In these cases $D(\tilde{e})\Sigma^k(e) = 0$ reduces to $d\Sigma^k(e) = 0$ for all $k$. From $d\Sigma^k(e) = 0$ and $D(e)\Sigma^k(e) = 0$, we obtain $\omega^k(e) = 0$ and the Ricci-flat Kähler metric.

$$\Lambda = 0 ; \quad R_{\mu\nu}(e) = 0, \quad ^{(+)}W_{\mu\nu\tau\sigma}(e) = 0, \quad \omega^k(e) = 0.$$  

{\Sigma^k(e)} define a Calabi-Yau metric on a K3-surface or a flat metric on $T^4$.

The gravitational instanton equations for a K3-surface with Calabi-Yau metrics and a four-torus with flat metrics reduce to

$$d\Sigma^k = 0 , \quad t.f. \Sigma^i \wedge \Sigma^j = 0.$$  

These equations give the Ricci-flat condition and restrict {\Sigma^k} to be a trio of closed Einstein-Kähler forms [8][14]. In Ref. 24, Plebanski used these equations to derive his ‘heavenly equations’. A manifold which satisfies Eq. (19) is called hyperkählerian. On hyperkählerian manifolds, a trio of Kähler forms $\{\Sigma^k(e)\}$ is represented by

$$\Sigma^k(e) = -\eta_{\alpha\beta}^k e^a \wedge e^b \propto g_{\alpha\beta} J^k_\gamma dz^\alpha \wedge d\bar{z}^\gamma ,$$

where $\{J^k\}$ are a trio of the $g$-orthogonal complex structures which satisfy the quaternionic relations and $g_{\alpha\beta}$ is an Hermite symmetric metric. $z$ and $\bar{z}$ denote complex local coordinates on these manifolds.

The moduli space is the equivalent class of a trio of the Einstein-Kähler forms (the hyperkähler forms) $\{\Sigma^k(e)\}$:

$$\mathcal{M}(\Sigma) = \{\Sigma^k \mid \Sigma^k \in su(2) \otimes \wedge^2 , t.f. \Sigma^i \wedge \Sigma^j = 0, \ d\Sigma^k = 0 \}/\{diff\ \text{eo.}\}.$$  

case b-2 (when the canonical line bundle $K$ is not trivial) :

$M_4$ is $K3/Z_2$, $K3/Z_2 \times Z_2$, or $T^4/\Gamma$ where $\Gamma$ is some discrete group.

In these cases, the reductions of $PU(2) \to PSU(2)_R$ are not possible because the canonical line bundles are not trivial. From Eqs. (25), (8) and (11), the Riemannian self-dual tensors are also derived;

$$\Lambda = 0 ; \quad R_{\nu\mu}(e) = 0 , \quad ^{(+)}W_{\mu\nu\tau\sigma}(e) = 0.$$  

(22)
The Hitchin’s theorem states that \( \{ \Sigma^k(e) \} \) form Einstein-Kähler metrics on these manifolds. In these cases \( Hol_0(g) \subset SU(2)_R \) but \( Hol_0(g) \neq Hol(g) \) is held. They are called as the locally hyperkählerian Kählerian manifolds and some informations from \( \omega^k \) and \( \Sigma^k \) will be needed to describe the moduli spaces.
III. BRST SYMMETRY

In this section we will explain the BRST symmetry of the model in the \( \Lambda \neq 0 \) case. Our action is invariant under the usual gravitational transformations, the restricted topological transformations. These transformations are invariant under the redundant transformations of them. We shall denote the BRST versions of the gravitational transf. \( \delta^{G}_c \), the restricted topological transf. \( \delta^{S} \) and the redundant transf. \( \delta^{G}_r \), respectively.

( For \( \Lambda = 0 \) this model belongs to the BF-type model so more careful investigations into the symmetries is necessary [26]. ) We introduce the following notations for the BRST symmetry:

**diffeo. \times SU(2) \rightarrow BRST**

\[
\begin{align*}
\text{ghost} & \quad \text{anti-ghost} & \quad \text{N-L field} \\
(\xi^\nu, v^k) & \rightarrow \tilde{c}^k \equiv (c^\nu, c^k) & \tilde{b}^k \equiv (b_\nu dx^\nu, b^k) & \tilde{\pi}^k \equiv (\pi_\nu dx^\nu, \pi^k)
\end{align*}
\]

**redundant diffeo. \times redundant SU(2) \rightarrow BRST**

\[
\begin{align*}
\text{ghost} & \quad \text{anti-ghost} & \quad \text{N-L field} \\
(\rho^\nu, \epsilon^k) & \rightarrow \tilde{\gamma}^k \equiv (\gamma^\nu, \gamma^k) & \tilde{\beta}^k \equiv (\beta_\nu dx^\nu, \beta^k) & \tilde{\tau}^k \equiv (\tau_\nu dx^\nu, \tau^k)
\end{align*}
\]

**restricted topological sym. \rightarrow BRST**

\[
\begin{align*}
\theta^i & \rightarrow \phi^i & \chi^{ij} & \pi^{ij}
\end{align*}
\]

The on-shell BRST transformations of this model are given by

\[
\begin{align*}
(1) \; \delta B\omega^j_\mu & = D_\mu c^j + (L_c \omega^j)_\mu + \frac{\Lambda}{12} \phi^j_\mu \\
& \equiv \delta^G_c \omega^j_\mu + \delta^S \omega^j_\mu, \\
(2) \; \delta B\Sigma^i_{\mu\nu} & = 2(\Sigma_{\mu\nu} \times c)^i + (L_c \Sigma^i)_{[\mu\nu]} + D_{[\mu} \phi^i_{\nu]} \\
& \equiv \delta^G_c \Sigma^i_{\mu\nu} + \delta^S \Sigma^i_{\mu\nu}, \\
(3) \; \delta Bc^i & = -(c \times c)^i + L_c c^i - \frac{\Lambda}{12} \gamma^i + \gamma^\sigma \omega^i_\sigma \\
& \equiv -(c \times c)^i + L_c c^i + \gamma^i, \\
(4) \; \delta Bb^i & = -2(b \times c)^i + L_c b^i + \pi^i, \\
(5) \; \delta B\pi^i & = 2(\pi \times c)^i + L_c \pi^i + \frac{\Lambda}{6} (b \times \gamma)^i + \gamma^\sigma D_\sigma b^i, \\
(6) \; \delta B\epsilon^i & = \epsilon^i \partial_\mu \epsilon^\mu - \gamma^i, \\
(7) \; \delta B\rho_\mu & = (L_c b)_\mu + \pi_\mu,
\end{align*}
\]
\begin{align}
\delta_B \pi_\mu &= (\mathcal{L}_c \pi)_\mu + (\mathcal{L}_\gamma b)_\mu, \\
\delta_B \gamma^i &= 2(\gamma \times c)^i + \mathcal{L}_c \gamma^i + \gamma^\sigma \phi^i_\sigma \\
&\implies \delta_B \hat{\gamma}^i = 2(\hat{\gamma} \times c)^i + \mathcal{L}_c \hat{\gamma}^i, \\
\delta_B \beta^i &= 2(\beta \times c)^i + \mathcal{L}_c \beta^i + \tau^i, \\
\delta_B \tau^i &= -2(\tau \times c)^i + \mathcal{L}_c \tau^i + \frac{\Lambda}{6} (\beta^i \times \gamma)^i + \gamma^\sigma D_\sigma \beta^i, \\
\delta_B \gamma^\mu &= \mathcal{L}_c \gamma^\mu, \\
\delta_B \beta^\mu &= (\mathcal{L}_c \beta)^\mu + \tau^\mu, \\
\delta_B \tau^\mu &= (\mathcal{L}_c \tau)^\mu + (\mathcal{L}_\gamma \beta)^\mu, \\
\delta_B \phi^i_\mu &= -2(\phi_\mu \times c)^i + (\mathcal{L}_c \phi^i)_\mu + D_\mu \gamma^i + 2\gamma^\sigma \Sigma^i_\sigma \\
&\equiv \delta^G G^i_\mu + \delta_\gamma^i \omega^i_\mu + \frac{24}{\Lambda} \gamma^\rho (F^i_\mu \rho - \frac{\Lambda}{12} \Sigma^i_\mu \rho), \\
\delta_B \chi^{ij} &= 2(\chi \times c)^{ij} + \mathcal{L}_c \chi^{ij} + \frac{\Lambda}{6} (\chi \times \gamma)^{ij} + \gamma^\sigma D_\sigma \chi^{ij}, \\
\delta_B \pi^{ij} &= \chi^{ij} - 2(\pi \times c)^{ij} + (\mathcal{L}_c \pi^{ij}),
\end{align}

where $\delta^G G^i_\mu$ denote the redundant transformations and are given by the replacement of the parameters $\hat{c} \rightarrow \hat{\gamma}$. The characteristic feature of our BRST symmetries is the presence of the restricted topological symmetry of the fundamental fields; $\delta^S \omega^i_\mu = \frac{\Lambda}{12} \phi^i_\mu$, $\delta^S \Sigma^i_\mu = D_\mu \phi^i_\nu$.

As already pointed out, this action comes to a Witten-type action for $\Lambda \neq 0$ under $\alpha \rightarrow 0$ limit by removing $\Sigma^k$ using the equation of motion. The restricted topological symmetry can be interpreted as the supersymmetry for a Witten-type model. The supersymmetric pair $(\delta \omega^k_\mu, \phi^k_\mu)$ is important because it forms a basis of the tangent space of the moduli space while the other pair $(\delta \Sigma^k_\mu, D_\mu \phi^k_\nu)$ is the auxiliary one and can be removed by using the equation of motion. The symmetries in the $\Lambda \neq 0$ case are interpretable as

$$\{SU(2) \times \text{diffeo.} \times \text{super sym.}\}/\{\text{redundant } SU(2) \times \text{redundant diffeo.}\}. \quad (24)$$

The transformations of these fields also end in those of the ordinary Witten-type theory even for off-shell except $\phi^k_\mu$ and $\Sigma^k_\mu$ by redefining the redundant $SU(2)$ ghost as $\hat{\gamma}^i \equiv -\frac{\Lambda}{12} \gamma^i + \gamma^\mu \omega^i_\mu$. The BRST symmetry of $\phi^j$ agrees with Witten-type theory on-shell. Thus this model coincides with the Witten-type topological gravity model given by Torre \cite{7} up to the secondary Chern number which is our classical action after eliminating $\Sigma^k$ under $\alpha \rightarrow 0$ limit.
From now on, we will replace Lie-derivative $\mathcal{L}_c (\mathcal{L}_\gamma)$ with the modified one $\tilde{\mathcal{L}}_c \omega^k_\mu \equiv (\mathcal{L}_c \omega^k)_\mu - D(c^\mu \omega^k_\mu) \quad (\tilde{\mathcal{L}}_\gamma \omega^k_\mu \equiv (\mathcal{L}_\gamma \omega^k)_\mu - D(\gamma^\mu \omega^k_\mu))$ so that $\delta_B \omega^k_\mu$ ($\delta_B \phi^k_\mu$) still remains in $P_{SU(2)} \times Adsu(2) \otimes \Lambda^1$,

$$(\tilde{\mathcal{L}}_c \omega^i_\mu)_\mu = 2 c^\tau F^i_{[\tau \mu]}, \quad \tilde{\mathcal{L}}_c \Sigma^i_{\mu \nu} = 2 D_{[\mu} c^\sigma \Sigma^i_{\sigma \nu]} + 3 c^\sigma D_{[\mu} \Sigma^i_{\sigma \nu]}. \quad (25)$$

Before we proceed, it will be useful to introduce general spin bundles $\Omega^{m,n}$, the space of fields with spin $(m, n)$ of $SU(2)_L \times SU(2)_R$ [27]. Let us denote by $\Omega^{1,0}$, $\Omega^{0,1}$ the two complex vector bundles on $M_4$ associated with the defining 2-dimensional representations of the two factors. These will only exist globally if $M_4$ is a spin manifold, i.e. the 2nd Stiefel-Whitney class $w_2(M_4) = 0$. Let us denote by $\Omega^{m,n} \equiv S^m \Omega^{1,0} \otimes S^n \Omega^{0,1}$ the tensor product of the $m$-th symmetric power bundle of $\Omega^{1,0}$ and the $n$-th symmetric power bundle of $\Omega^{0,1}$. For example, the space of $P_{SU(2)} \times Adsu(2)$ valued 1-forms $\delta \omega^k$ is $\Omega^{2,0} \otimes \Lambda^1 \simeq \Omega^{2,0} \otimes \Omega^{1,1}$ while the space of $(\xi^\mu, \upsilon^k)$ is equivalent to $\Lambda^1 \oplus \Omega^{2,0} \simeq \Omega^{1,1} \oplus \Omega^{2,0}$ (see Table 2).
IV. ZERO MODES IN THE $\Lambda \neq 0$ CASE

To know the number of zero modes in the quantum action $S_q$, we consider the moduli space $\mathcal{M}$ defined by our instanton equations Eq. (16) for conformally self-dual Einstein manifolds.

$$\mathcal{M}(\omega) = \{\omega^k|\omega^k \in su(2) \otimes \Omega^{1,1}, \ t.f. F^i \wedge F^j = 0\}/\{SU(2) \times diff eo.\} .$$

Given a solution $(\Sigma^k_0, \omega^k_0)$ of the instanton equations, the tangent space $T(\mathcal{M})$ of $\mathcal{M}$ is the space of infinitesimal deformations $\delta\omega^k$ which satisfy linearized instanton equations modulo deformations generated by $SU(2)$ (the subgroup of $SO(4)$) transformation and diffeomorphism:

$$T(\mathcal{M}(\omega)) = \{\delta\omega^k|\delta\omega^k \in \Omega^{2,0} \otimes \Omega^{1,1}, D_1\delta\omega^k = 0\}/\{SU(2) \times diff eo.\} .$$

where

$$D_1\delta\omega^k \equiv t.f. F^i_0 \wedge D\delta\omega^j = 0 .$$

This linearized instanton equation is derived by substituting equation $D\delta\omega^k - \frac{\Lambda}{\Omega}\delta\Sigma^k = 0$ into $t.f. \Sigma^i_0 \wedge \delta\Sigma^j = 0$.

We define the following sequence of mappings on a compact conformally self-dual Einstein manifold in terms of the spin bundles:

$$0 \overset{D_{-1}}{\longrightarrow} C^\infty(\Omega^{1,1} \oplus \Omega^{2,0}) \overset{D_0}{\longrightarrow} C^\infty(\Omega^{2,0} \otimes \Omega^{1,1}) \overset{D_1}{\longrightarrow} C^\infty(\Omega^{4,0}) \overset{D_2}{\longrightarrow} 0 ,$$

where the symbol sequence is

$$V_0 \quad V_1 \quad V_2$$

$$0 \rightarrow \Omega^{1,1} \oplus \Omega^{2,0} \rightarrow \Omega^{2,0} \otimes \Omega^{1,1} \rightarrow \Omega^{4,0} \rightarrow 0 .$$

In the above sequence $D_{-1}$ and $D_2$ are identically zero operators. The operator $D_0$ is defined by

$$D_0(\xi^\mu, v^k) \equiv \tilde{\mathcal{L}}_\xi \omega^k + Dv^k .$$

We can easily check the ellipticity of the deformation complex. Defining the inner product in each space $V_i$, we can introduce the adjoint operators $D_0^*$ and $D_1^*$ for $D_0$ and $D_1$ respectively and the Laplacians $\triangle_i$; $\triangle_0 = D_0^*D_0$, $\triangle_1 = D_0D_0^* + D_1^*D_1$, $\triangle_2 = D_1D_1^*$. We may then define the cohomology group on each $V_i$,

$$H^i \equiv Ker D_i/Im D_{i-1} .$$
It is easy to show that $H^i$ is equivalent to the kernel of $\triangle_i$, the harmonic subspace of $V_i$. These cohomology groups are finite-dimensional. We call the dimension of $H^i$ $h^i$. The $H^1$ is exactly identical with the tangent space of $\mathcal{M}(\omega)$ in Eq. (27), the dimension of which we need to know. On the space $V_0$, $H^0$ is equal to Ker $D_0$ because the image of $D_{-1}$ is trivial. In the $\Lambda \neq 0$ case, Torre found that Ker $D_0$ is equivalent to the space of the Killing vectors [7]. The kernel of $D_2$ is the whole of the space $V_2$. Hence $H^2$ is the subspace of $V_2$ orthogonal to the mapping $D_1$, or equivalently it is the kernel of $D_1^*$. The index of the elliptic complex is defined as the alternating sum,

$$\text{Index} \equiv h^0 - h^1 + h^2 \ . \tag{32}$$

By applying the Atiyah-Singer index theorem [28] to the elliptic complex, we obtain

$$\text{Index} = \int_{M_4} \frac{\text{ch}(\Omega^{2,0} \oplus \Omega^{1,1} \ominus \Omega^{2,0} \otimes \Omega^{1,1} \oplus \Omega^{4,0}) \text{td}(TM_4 \otimes \mathbb{C})}{e(TM_4)} = \int_{M_4} \frac{\text{ch}(\Omega^{2,0} \ominus \Omega^{3,1} \oplus \Omega^{4,0}) \text{td}(TM_4 \otimes \mathbb{C})}{e(TM_4)}$$

$$= 5 \chi - 7 \tau,$$

where $\text{ch}$, $e$ and $\text{td}$ are the Chern character, Euler class and Todd class of the various vector bundles involved. Therefore the alternating sum of $h^i$ in Eq. (32) is determined by the Euler number $\chi$ and Hirzebruch signature $\tau$. By changing $\tau \rightarrow |\tau|$, this index can also be adopted to manifolds with the opposite orientation.

If $\Lambda > 0$, $h^1$ and $h^2$ are found to be zero as shown by Torre [7]. The result such as $h^1 = 0$ for the $\Lambda > 0$ case agrees with the one of Perry and Teo. They showed that the dimension of the moduli space of conformally self-dual metrics is zero on $S^4$ or $CP^2$ by using the deformation complex for the metrics [6]. Therefore from Eqs. (32) and (33), the dimension $h^0$ is equal to the index,

$$h^0 = 5 \chi - 7 \tau , \quad h^1 = h^2 = 0 \ . \tag{34}$$

The value of $h^0$, the dimension of the Killing vector space, agrees with that obtained by a different method in Ref. 23. For $S^4$ with the standard metric, the dimension of the isometry is given by dim. $SO(5) = 10$, which coincides with $h^0 = 5 \chi - 7 \tau |_{\tau = 0, \chi = 2} = 10$. For $CP^2$ with the Fubini-Study metric, the
dimension of the isometry is given by \( \text{dim. } SU(3) = 8 \) which agrees with
\[ h^0 = 5\chi - 7\tau \big|_{\tau=1,\chi=3} = 8. \]
If \( \Lambda < 0 \), \( h^0 \) becomes zero \([7]\), although \( h^1 \) and \( h^2 \) are
not completely determined;
\[ h^0 = 0 , \quad h^2 - h^1 = 5\chi - 7\tau . \] (35)

For conformally self-dual Einstein manifolds with \( \Lambda < 0 \), there are two
known examples, which are hyperbolic surface/\( \Gamma \) and boundary domain/\( \Gamma \) where
\( \Gamma \) is some discrete subgroup. The dimensions of their moduli spaces of
conformally self-dual Einstein metrics are zero due to the Mostov’s rigidity
\([29]\). Thus in these cases the dimensions of the moduli spaces of the anti-
self-dual frame connections are also zero.
V. THE PARTITION FUNCTION IN THE $\Lambda \neq 0$ CASE

For the purpose of the calculation of the partition function, we first decompose $\omega^k$ and $\Sigma^k$ fields as follows;

$$\omega^k = \omega_0^k + \delta\omega^k,$$
$$\Sigma^k = \Sigma_0^k + \delta\Sigma^k,$$

where $\omega_0$ and $\Sigma_0^k$ are the background solutions of conformally self-dual Einstein manifolds. $\delta\omega^k$ and $\delta\Sigma^k$ are quantum fluctuations (infinitesimal deformations).

The BRST quantization of the Witten-type topological gravity model in the $\Lambda \neq 0$ case is straightforward. Twelve gauge fixing conditions for the super symmetry and seven ones for SU(2) × diff. are imposed. The gauge fixing conditions for the super symmetry consist of five gauge fixing conditions for the super symmetry except for the redundancy and seven fixing conditions to remove the freedom of the redundant symmetries. We are fixing the gauge to be $D_0^*\delta\omega^k = 0$ for the diffeomorphism and SU(2) and $D_0^*\phi^k = 0$ for the redundant diffeomorphism and redundant SU(2);

$$D_0^*\delta\omega^k \equiv (\tilde{L}_c^*\delta\omega^k, D^*\delta\omega^k) = 0,$$
$$D_0^*\phi^k \equiv (\tilde{L}_c^*\phi^k, D^*\phi^k) = 0,$$

red. diff. red. SU(2)

$$D_1^{-1} = t.f. F^i \wedge D\delta\omega^i = 0,$$

super/$\{\text{red. diff. × red. SU(2)}\}$

where * denotes the Hodge star dual operation and $O^* \equiv -O$ is the adjoint operator of $O$. The operator $D_0^* : C^\infty(\Omega^{2,0} \otimes \Lambda^1) \to C^\infty(\Omega^{2,0} \otimes \Lambda^0)$ is the adjoint operator of $D_0 : \tilde{\epsilon}^k \to \delta\omega^k$,

$$D_0\tilde{\epsilon}^k(\omega) \equiv \tilde{L}_c\omega^k + D_\tau\epsilon^k dx^\tau = 2\epsilon^\nu D_i[\nu,\omega^k] dx^\tau + D_\tau\epsilon^k dx^\tau,$$

where $D = d + (\omega \times \cdot)$. The elements of the image of $D_1 : C^\infty(\Omega^{2,0} \otimes \Lambda^1) \to C^\infty(\Omega^{4,0} \otimes \Lambda^4)$ are 4-forms with symmetric trace-free SU(2) indices, i.e. sections of $\Omega^{4,0} \otimes \Lambda^4 \simeq \Omega^{2,0} \otimes \Lambda^0$. 

The gauge fixed quantum action is given by

\[ S_q = S_{TG} + \int \delta_B \{ \chi_{ij}(D_1 \delta \omega)^{ij} + \bar{b}_k \ast D_0^* \delta \omega^k + \bar{\beta}_k \ast D_0^* \phi^k \} \]  

When expanded out by using the properties of \( \delta_B \) in Eq. (23), Eq. (41) reads

\[ S_q = S_{TG} + \]

\[ + \int \pi_{ij}(D_1 \delta \omega)^{ij} + \bar{\pi}_k \ast D_0^* \delta \omega^k + \bar{b}_k \ast D_0^* D_0 \bar{c}^k(\omega) + \bar{b}_k \ast D_0^* \phi^k \]

\[ + \int \chi_{ij}(D_1 \phi)^{ij} + \bar{\tau}_k \ast D_0^* \phi^k + \bar{\beta}_k \ast D_0^* D_0 \bar{\gamma}^k(\omega) + \bar{\beta}_k \ast D_0^* D_0 \bar{c}^k(\phi) \]

\[ + \text{ other higher order terms.} \]  

(42)

We are now ready to evaluate the partition function.

\[ Z = \int DX (-S_q) \]

where \( DX \) represents the path integral over the fields such as \( \delta \Sigma^k, \delta \omega^k \), ghosts, anti-ghosts, N-L fields, etc. The Gaussian integrals over the commuting \( \bar{\beta} - \bar{\gamma} \) set of fields in Eq. (42) yields the determinant \( (\det \Delta_0)^{-1} \) which cancels with the \( \det \Delta_0 \) contribution coming from the anti-commuting set of fields \( \bar{b} - \bar{c} \) set. The term \( \bar{b}_k \ast D_0^* D_0 \bar{c}^k(\phi) \) is three-point interaction of ghosts so does not contribute to the partition function.

Consider now two terms \( \bar{\tau}_k \ast D_0^* \phi^k \) and \( \chi_{ij}(D_1 \phi)^{ij} \) (we absorb the \( \bar{b}_k \ast D_0^* \phi^k \) term into the \( \bar{\tau}_k \ast D_0^* \phi^k \) term). In calculating their determinants we use a differential operator \( T = D_0^* \oplus D_1 \) and its adjoint operator \( T^* \);

\[ T \]

\[ T^* T \ ; \ \Omega^{2,1} \oplus \Omega^{1,1} \rightleftharpoons \Omega^{0,0} \oplus \Omega^{2,0} \oplus \Omega^{1,0} \]

\[ T^* \]  

(44)

One could show \( \det T = \det \frac{1}{2} (T^* T) = (\det \Delta_1)^{\frac{1}{2}} \) by using matrix notations for \( T \) and \( T^* \). The \( \bar{\pi}_k - \delta \omega^k - \pi_{ij} \) system of commuting fields gives \( (\det \Delta_1)^{-\frac{1}{2}} \) which cancels with the determinant \( \bar{\tau}_k - \phi^k - \chi_{ij} \) system of anti-commuting fields.

Since the moduli space has a vanishing dimension \( h^1 = 0 \) for the \( \Lambda > 0 \) case, it consists of isolated points such as \( CP^2 \) with the Fubini-Study metric or \( S^4 \) with the standard metric. We can write the partition function as

\[ Z = \Sigma_{\text{instanton}} (\det \Delta_1)^{-\frac{1}{4}} (\det \Delta_0)^{-1} (\det \Delta_1)^{\frac{1}{4}} (\det \Delta_0) = \Sigma_{\text{instanton}} \pm 1 = \pm 1 \]  

(45)
up to the secondary Chern class by projecting out $h^0$ zero modes.

We comment the BRST symmetry of the $\Lambda = 0$ case briefly. Substituting $\Lambda = 0$ in Eq. (23) the restricted topological symmetry of the fundamental fields are $\delta^S \omega^k_\mu = 0$, $\delta^S \Sigma^{k}_{\mu\nu} = D_{[\mu} \phi^k_{\nu]}$. The difference is apparent from the Witten type topological model given by Kunitomo [8], which has the following transformation for the fundamental fields $\delta^S \omega^k_\mu = \delta^k_\mu$, $\delta^S \Sigma^{k}_{\mu\nu} = \Psi^k_{[\mu\nu]}$. The fermionic ghost zero modes for $\phi^k_\mu$ of our model are contained in the basis of the tangent space of the moduli space and further investigation is necessary to know the precise value of the dimension.

However on a $K3$-surface and $T^4$, the special situation occurs ; $\omega^k$ can be gauged away for on-shell and the topological symmetry reduces to $\delta^S \Sigma^k = d\phi^k$. The number of the free parameters of this symmetry is not 12 but 9 due to the redundancy of $\{d^2\phi = 0/d^3\phi = 0\}$. There is no need to fix $SU(2)$ and redundant $SU(2)$ in this case. We only fix five degrees of the restricted topological symmetry and four degrees of diffeomorphism and four degrees of the redundant diffeomorphism [26].
VI. THE DIMENSION OF THE MODULI SPACE IN THE $\Lambda = 0$ CASE

We focus our attention on two cases; a four-torus with flat metrics and a $K3$-surface with Calabi-Yau metrics.

For a $K3$-surface with Calabi-Yau metrics and a four-torus with flat metrics, the moduli space is represented only by the deformations of a trio of Einstein-Kähler forms (hyperkähler forms) due to our prerequisite conditions for $P$-bundle on $M_4$ and the gauge fixing conditions.

Let $K(g)$ be the moduli space of Einstein-Kähler forms on $M_4$, $\epsilon(g)$ be the moduli space of Einstein metrics, and $C(g)$ be the moduli space of complex structures, respectively. They are the equivalent classes under the all diffeomorphism. At first we quote the result about the dimension of $K(g)$ briefly when $M_4$ is a Kählerian manifold with vanishing real first Chern class, which is given by Ref. 23. Then we clarify the difference between $\mathcal{M}(\Sigma)$, i.e. the moduli space of hyperkähler forms defined by Eq. (21) and the moduli space $K(g)$.

When the real first Chern class is zero, the deformation of the Kähler class with a fixed complex structure induces a deformation of a Einstein metric from the Calabi-Yau theorem. The deformation of Einstein-Kähler forms $\{\Sigma\}$ consists of those of Einstein metrics $\{g\}$ and of complex structures $\{J\}$ and needs a careful examination of its degenerated part,

$$\delta \Sigma = \delta g \circ J + g \circ \delta J \sim h \circ J + g \circ I,$$

where $I = \frac{d}{dt} J(t) \mid_{t=0}$ is the variation of complex structure $J(t)$ of $J$ and $h = \frac{d}{dt} g(t) \mid_{t=0}$ is the variation of Kähler-Einstein metric $g(t)$ of $g$. We quote the results of the dimensions about $\epsilon(g)$, $C(g)$ and $K(g)$ in order.

(1) Deformation of Einstein-Kähler Metrics:

If some infinitesimal Einstein deformations of Einstein-Kähler metric $g$ are contravariant two-tensor $h$, then they are decomposed into its hermitian part $h_h$ and anti-hermitian part $h_{ah}$; $\{h\} = \{h_h\} \oplus \{h_{ah}\}$,

$$\{h_h\} = \{h \mid h(Ju, Jv) = h(u, v)\}, \quad \{h_{ah}\} = \{h \mid h(Ju, Jv) = -h(u, v)\},$$

where $u, v \in TM_4$. It is easy to see that both $\{h_h\}$ and $\{h_{ah}\}$ are infinitesimal Einstein deformations. $\{h_h \circ J\}$ are shown to be the real $(1,1)$ harmonic differential 2-forms and orthogonal to the Kähler forms (which means the
fixing of the scale factor). Therefore they form a space whose dimension is \( \dim H^{(1,1)}_R(M,J) - 1 \).

(2) Deformation of Complex Structures:

According to the Kodaira-Spencer deformation theorem [31], the tangent space of the moduli space of complex structures is isomorphic to \( 2H^1_C(M,\Theta) \) in our case, where \( \Theta \) is the sheaf of the germs of holomorphic vector fields. The deformation of complex structures is separated into two parts. The one is anti-symmetric complex deformation and the other is the symmetric one. The dimension of the anti-symmetric one \( \{I_{as}\} \) is given by \( 2\dim H^1_C(M,\Theta) - 2\dim H^{(2,0)}_C(M,J) \).

(3) Deformation of Einstein-Kähler Forms:

The degenerated part of the deformations of the Einstein-Kähler forms consists of the anti-hermitian Einstein deformations \( \{h_{ah} \circ J\} \), and the symmetric complex deformations \( \{g \circ I_s\} \). The former counterbalances the latter; \( g \circ I_s + h_{ah} \circ J = 0 \) and their correspondence is shown to be bijective. The dimension of \( \{I_s\} \) is the same as that of \( \{h_{ah}\} \) and is given by \( 2\dim H^1_C(M,\Theta) - 2\dim H^{(2,0)}_C(M,J) \). Consequently infinitesimal deformations of the Einstein-Kähler form is represented by

\[
\delta \Sigma = \frac{\vphantom{\frac{\dim H^{(1,1)}_R(M,J) - 1}{\dim \epsilon(g)}} h_{kh} \circ J \quad \left\{ \begin{array}{c} \text{dim}_R H^{(1,1)}_R(M,J) - 1 \end{array} \right\}_{\text{dim} \epsilon(g)} + (h_{ah} \circ J) \quad \left\{ \begin{array}{c} \text{dim} \epsilon(g) \end{array} \right\} \quad \left\{ \begin{array}{c} \text{dim} \epsilon(g) = \dim \epsilon(g) \end{array} \right\} \quad \left\{ \begin{array}{c} \text{dim} \epsilon(g) = \dim \epsilon(g) \end{array} \right\} \quad \left\{ \begin{array}{c} \text{dim} \epsilon(g) = \dim \epsilon(g) \end{array} \right\} \\
\quad + g \circ I_s + g \circ I_{as} \quad \left\{ \begin{array}{c} \text{dim} \epsilon(g) = \dim \epsilon(g) \end{array} \right\}.
\]

Finally, the dimensions of moduli spaces can be summarized for Einstein metrics, for complex structures and for Einstein-Kähler forms over the Kählerian manifolds with \( c_1(M)_R = 0 \),

\[
\dim \epsilon(g) = \dim H^{(1,1)}_R(M,J) - 1 + 2\dim H^1_C(M,\Theta) - 2\dim H^{(2,0)}_C(M,J), \quad (49)
\]

\[
\dim C(g) = 2\dim H^1_C(M,\Theta), \quad (50)
\]

\[
\dim K(g) = \dim H^{(1,1)}_R(M,J) - 1 + 2\dim H^1_C(M,\Theta). \quad (51)
\]
One can show that the canonical line bundle $K$ is trivial over a $K3$-surface or over $T^4$, and that there is a nowhere vanishing holomorphic 2-form $\lambda$. The isomorphism of sheaves due to $\lambda$ and the Dolbeaut theorem: $H_C^1(M, \Theta^1) \cong H_C^1(M, \Omega^1) \cong H^{(1,1)}(M, C)$, leads to the following equations,

$$\dim. \epsilon(g) = 3\dim. H^{(1,1)}(M, C) - 1 - 2\dim. H^{(2,0)}(M, C), \quad (52)$$
$$\dim. C(g) = 2\dim. H^{(1,1)}(M, C), \quad (53)$$
$$\dim. K(g) = 3\dim. H^{(1,1)}(M, C) - 1. \quad (54)$$

The results for a $K3$-surface and $T^4$ are given by

$$K3: \begin{cases} 
\dim. K(g) = 59, \\
\dim. C(g) = 40, \\
\dim. \epsilon(g) = 57,
\end{cases}$$

by substituting $b^{1,1} = 20$ and $b^{2,0} = 1$ and

$$T^4: \begin{cases} 
\dim. K(g) = 11, \\
\dim. C(g) = 8, \\
\dim. \epsilon(g) = 9,
\end{cases}$$

by substituting $b^{1,1} = 4$ and $b^{2,0} = 1$ except for a scale factor.

The difference between $\mathcal{M}(\Sigma)$ and $K(g)$ is as follows; the moduli space of the Einstein-Kähler forms $K(g)$ is defined in terms of $(g, J^1)$ or equivalently $\Sigma^1$ only. On the other hand, the definition of $\mathcal{M}(\Sigma)$ specifies a set of $(g, J^1, J^2, J^3)$ or equivalently $(\Sigma^1, \Sigma^2, \Sigma^3)$, which takes into account the degrees of freedom how one can choose $g$ and a trio of the $g$-orthogonal complex structures up to a scale factor.

Before we present the difference between $\dim. \mathcal{M}(\Sigma)$ and $\dim. K(g)$, let us show that the degrees of freedom of a trio of $g$-orthogonal complex structures which satisfy the quaternionic relations for a fixed $g$ is 3 (see Appendix II).

For a fixed $g$,

$$\{ \text{$g$-orthogonal quaternionic almost complex structures } J^1 \} \cong S^2 \cong \text{ImH} \mid_{x_1^2 + x_2^2 + x_3^2 = 1}, \quad (55)$$

where $\text{ImH}$ represents the imaginary part of the field of the quaternion $H$;

$$\text{ImH} \equiv \{ J^1 = x_1 J^1 + x_2 J^2 + x_3 J^3 \mid (J^1)^2 = (J^2)^2 = (J^3)^2 = -1, J^1 J^2 = -J^2 J^1 = J^3, \} \quad (56)$$

$$\quad (x_1, x_2, x_3) \in \mathbb{R}^3 \quad J^2 J^3 = -J^3 J^2 = J^1, J^3 J^1 = -J^1 J^3 = J^2 \}$$

The degrees of freedom how one can choose $J^1$ for a fixed $g$ is given by \( \dim S^2 = 2 \). The region of $J^2$ which is orthogonal to $J^1$ for a fixed pair $(g, J^1)$ is equivalent to $S^1$ over $S^2$. $J^3$ is automatically arranged after $(g, J^1, J^2)$ are fixed.

From these facts, the difference between $\dim K(g)$ and $\dim \epsilon(g)$ is given by 2, which corresponds to $\dim S^2$ (the degrees of freedom of how to choose $J^1$ for a given $g$) and coincides with $2 \dim H^{(2,0)}(M, C) = 2$ (the degrees of freedom of how to choose $J^1 + \delta J^1$ for a fixed $g + \delta g$) up to a scale factor. The difference between $\dim K(g)$ and $\dim \mathcal{M}(\Sigma)$ is given by $\dim S^1 = 1$ up to a scale factor.

After all the dimension of our moduli space becomes as follows;

$$\dim \mathcal{M}(\Sigma) = 60 \text{ for } K3, \quad \dim \mathcal{M}(\Sigma) = 12 \text{ for } T^4,$$

up to a scale factor. In fact, we have confirmed the dimension of the moduli space $\mathcal{M}(\Sigma)$ by applying Atiyah-Singer Index theorem to the deformation complex (we will report this in the next paper [26].)

The moduli space $\mathcal{M}(\Sigma)$ has a bundle structure with the fiber $(J^1, J^2, J^3)$ over the base manifold which is the moduli space of the Einstein metrics up to a scale factor;

$$\mathcal{M}(\Sigma) \quad \uparrow$$

$$\dim \mathcal{M}(\Sigma) = \dim K(g) + 1 = \dim \epsilon(g) + 3$$

$$\uparrow$$

$$K(g) \quad \uparrow$$

$$\dim K(g) = \dim \epsilon(g) + 2.$$
VII. CONCLUSION

In this paper, we have presented a topological version of 2-form Einstein gravity in four dimensions. For a compact manifold in the \( \Lambda \neq 0 \) case, we have defined the elliptic complex associated with the moduli space of our theory. By applying the Atiyah-Singer index theorem in the \( \Lambda \neq 0 \) case, we have evaluated the index of the elliptic complex and the partition function. In the \( \Lambda = 0 \) case, we have clarified the dimension of the moduli space which is related to the Plebansky’s equations for \( T^4 \) and a \( K3 \) surface.

It would be intriguing to study the \( \Lambda = 0 \) case, since the relation of four-dimensional (Riemann) self-dual gravity and two-dimensional conformal field theory has been investigated. In fact, Park showed that the former arises from a large \( N \)-limit of the two-dimensional sigma model with SU(\( N \)) Wess-Zumino terms only [32]. Our topological model will be useful to understand the relation and to develop the self-dual gravity.

As another approach, it would also be interesting to extend BF-type model in the \( \Lambda = 0 \) case to the super BF-type model [8]. Since the dimension of the moduli space is non-zero, there arise as many fermionic zero-modes as the dimension, which make the partition function trivial. To avoid this we need some functional \( \mathcal{O} \) which absorbs the zero-modes. If one calculates the vacuum expectation value of the ‘observable’ \( \mathcal{O} \), then it may provide non-trivial information such as a differential invariant to distinguish differential structures on these manifolds. Such a functional \( \mathcal{O} \) is required to be BRST invariant to preserve the topological nature of the theory and may be obtained from the BRST descendant equations as in two-dimensional topological gravity [4].

The extension of the algebraic curves (one-dimensional compact complex manifolds) with Einstein metrics to four dimensions may be the algebraic surfaces (two-dimensional compact complex manifolds) with Einstein metrics. \( T^4 \) and a \( K3 \)-surface belong to the algebraic surfaces. To construct the topological gravity models by taking another gauge fixing conditions, which describe these algebraic surfaces is worth pursuing.
ACKNOWLEDGMENT

We are grateful to Q-Han Park and S. Morita for useful discussions. We also acknowledge N. Sakai for useful discussions and careful reading of the manuscript. One of us (M. A.) thanks A. Futaki most for pointing out the difference between $K(g)$ and $M(\Sigma)$ and the necessity of an almost complex structure with vanishing real first Chern class for the $\Lambda = 0$ case.
APPENDIX I : PROPERTIES OF THE $\eta$ SYMBOLS

We list some useful identities of the $\eta^k_{ab}$ [21]:

\[ \eta^k_{ab} = \epsilon_{cab} \quad \text{for} \quad a, b = 1, 2, 3. \]
\[ \eta^k_{0a} = \eta^k_{a0} = \delta^k_a \quad \text{for} \quad a = 0, 1, 2, 3. \quad (58) \]

(1) $\eta^k_{ab} = -\eta^k_{ba}$,
(2) $\eta^k_{ab} = -\frac{1}{2} \epsilon_{ab} \eta^c_{cd}$,
(3) $\eta^k_{ab} \eta^k_{cd} = 2(\delta^e_a \delta^d_b - \frac{1}{2} \epsilon_{abcd}) \equiv 2 P^e_{ab} cd$,
(4) $\eta^k_{ab} \eta^l_{c} = 2\delta^k_l \delta^a_c + \epsilon_{klm} \eta^n_{ac}$, \quad (59)

where $\epsilon_{klm}$ and $\epsilon_{abcd}$ denote the anti-symmetric constant tensors.

From Eqs.(3) and (4), the identities of $\Sigma^k(e)$ are derived :

(5) $\Sigma^k_{\mu\nu}(e) \Sigma^{k\tau\rho}(e) = 2 P^e_{\mu\nu\tau\rho}$,
(6) $\Sigma^k_{\mu\nu}(e) \Sigma^{I}_{\mu\nu}(e) = -\delta^I_k \delta^\rho_\mu + \epsilon_{klm} \Sigma^{n\rho}_{\mu}(e)$.
APPENDIX II : SOME DEFINITIONS, THEOREMS AND PROPOSITION

In this appendix, we put some definitions, theorems and proposition which we have used.

Theorem ( S. Kobayashi and K. Nomizu [22] )

Let $P(M,G)$ be a principal fibre bundle with a connection $\Gamma$, where $M$ is connected and paracompact. Let $u_0$ be an arbitrary point $P$. Denote by $P(u_0)$ the set of points in $P$ which can be joined to $u_0$ by a horizontal curve. Then

(1) $P(u_0)$ is a reduced bundle with structure group $Hol(g)$.
(2) The connection $\Gamma$ is reducible to a connection in $P(u_0)$.

Theorem ( E. Calabi and Yau [30] )

Let $M$ be a compact Kählerian manifold, $\Sigma$ is its Kähler form and Any closed (real) 2-form of type $(1,1)$ belonging to $2\pi c_1(M)_R$ is the Ricci form of one and only one Kähler class $\Sigma$.

As an immediate consequence, we get the following fact:

the compact Kählerian manifolds with zero real first Chern class are exactly the compact complex manifolds admitting a Kähler metric with zero Ricci form (equivalently with restricted holonomy group contained in the special unitary group.)

Definition 1 (Besse [24])

A $4n$-dimensional Riemannian manifold is called
(a) hyperkählerian if its holonomy group is contained in $SP(n)$.
(b) locally hyperkählerian if its restricted holonomy is contained in $SP(n)$.

Definition 2 (Besse [24])

A $4n$-dimensional Riemannian manifold is called
(a) quaternion-Kähler if its holonomy group is contained in $SP(N) \times SP(1)$
(a) locally quaternion-Kähler if its restricted holonomy group is contained in $SP(N) \times SP(1)$
Proposition 1 (Besse [24])

A Riemannian manifold \((M, g)\) is hyperkählerian if and only if there exist on \(M\) two complex structures \(J^1\) and \(J^2\) such that

(a) \(J^1\) and \(J^2\) are parallel (i.e. \(g\) is a Kähler metric for each.)

(b) \(J^1 J^2 = -J^2 J^1\)

Notice that \(J^3\) is still a parallel complex structure on \(M\) and more generally, given \((x_1, x_2, x_3)\) in \(R^3\) with \(x_1^2 + x_2^2 + x_3^2 = 1\), then the complex structure \(J = x_1 J^1 + x_2 J^2 + x_3 J^3\) on \(M\) is still parallel. So there is a whole manifold (isomorphic to \(S^2\)) on parallel complex structure on \(M\).
