In this pedagogical review, we summarize the mathematical basis and practical hints for the explicit analytical computation of spectral sums that involve the eigenvalues of the Laplace operator in simple domains such as $d$-dimensional balls (with $d = 1, 2, 3$), an annulus, a spherical shell, right circular cylinders, rectangles and rectangular cuboids. Such sums appear as spectral expansions of heat kernels, survival probabilities, first-passage time densities, and reaction rates in many diffusion-oriented applications. As the eigenvalues are determined by zeros of an appropriate linear combination of a Bessel function and its derivative, there are powerful analytical tools for computing such spectral sums. We discuss three main strategies: representations of meromorphic functions as sums of partial fractions, Fourier–Bessel and Dini series, and direct evaluation of the Laplace-transformed heat kernels. The major emphasis is put on a pedagogic introduction, the practical aspects of these strategies, their advantages and limitations. The review gathers many summation formulas for spectral sums that are dispersed in the literature.

Keywords: Laplacian eigenvalues; Bessel functions; spectral sums; summation formulas; heat kernel; diffusion.

1. Introduction

The Laplace operator, $\Delta = \nabla^2$, plays the central role in mathematical physics and found countless applications in quantum mechanics, acoustics, chemical physics, biology, heat transfer, hydrodynamics, nuclear magnetic resonance, and stochastic processes [1-9]. In a bounded Euclidean domain $\Omega \subset \mathbb{R}^d$, the Laplace operator has a discrete spectrum, i.e. a countable number of eigenvalues $\lambda_m$ and eigenfunctions
D. S. Grebenkov

\( U_m \) satisfying

\[-\Delta U_m = \lambda_m U_m \text{ in } \Omega,\]

\( \ell \frac{\partial}{\partial n} U_m + U_m = 0 \text{ on } \partial \Omega,\]

subject to Dirichlet (\( \ell = 0 \)), Neumann (\( \ell = \infty \)) or Robin (\( 0 < \ell < \infty \)) boundary condition on a smooth boundary \( \partial \Omega \), with \( \partial / \partial n \) being the normal derivative oriented outward the domain \( \Omega \) (the Neumann case can formally be understood as the limit \( \ell \to \infty \); in particular, the boundary condition (1.2) reads \( \partial U_m / \partial n = 0 \)). The eigenvalues are non-negative and grow to infinity, \( 0 \leq \lambda_1 \leq \lambda_2 \leq \ldots \to +\infty \), whereas the eigenfunctions form an orthonormal complete basis in the space \( L_2(\Omega) \) of square integrable functions on \( \Omega \). In particular, the eigenvalues and eigenfunctions determine the Green’s functions of homogeneous diffusion and wave equations and thus allow for solving most common boundary value problems [10–12]. For instance, the spectral decomposition

\[ P(x, t \mid x_0) = \sum_{m=1}^{\infty} U_m(x) U^*_m(x_0) e^{-Dt\lambda_m} \]

determines the Green’s function of the diffusion (or heat) equation,

\[ \frac{\partial}{\partial t} P(x, t \mid x_0) = D\Delta P(x, t \mid x_0) \text{ in } \Omega,\]

subject to the same boundary condition as Eq. (1.2) and the initial condition \( P(x, t = 0 \mid x_0) = \delta(x - x_0) \), where \( \delta \) is the Dirac distribution, \( D \) is the diffusion coefficient, \( x_0 \) is a fixed point in \( \Omega \), and the asterisk denotes the complex conjugate. This Green’s function, also known as the heat kernel or propagator, describes various properties of diffusion-controlled processes in reactive media [13–18]. In turn, the Laplace transform of the heat kernel,

\[ \tilde{P}(x, p \mid x_0) = \int_0^\infty dt e^{-pt} P(x, t \mid x_0) = \sum_{m=1}^{\infty} \frac{U_m(x) U^*_m(x_0)}{p + D\lambda_m} \]

is the Green’s function of the modified Helmholtz equation,

\[ (p - D\Delta) \tilde{P}(x, p \mid x_0) = \delta(x - x_0) \text{ in } \Omega, \]

subject to the same boundary condition as Eq. (1.2), and the tilde denotes the Laplace transform.

The spectral decomposition (1.3) and formulas derived from it determine most diffusion-based characteristics. An emblematic example is the heat trace,

\[ Z(t) = \int_\Omega dx_0 P(x_0, t \mid x_0) = \sum_{m=1}^{\infty} e^{-D\lambda_m t} \]

subject to the same boundary condition as Eq. (1.2) and the initial condition \( P(x, t = 0 \mid x_0) = \delta(x - x_0) \).
A physicist’s guide to explicit summation formulas

which can be interpreted as the probability density of the return to the starting point $x_0$, averaged over the starting point. This quantity is also known as the return-to-the-origin probability \[19–21\]. Its Laplace transform,

$$
\tilde{Z}(p) = \int_0^\infty dt \ e^{-pt} \ Z(t) = \sum_{m=1}^\infty \frac{1}{p + D\lambda_m},
$$

(1.8)

is one of the simplest spectral sums.

Another important example is the survival probability of a particle diffusing in a domain with perfectly or partially absorbing boundaries:

$$
S(t \mid x_0) = \mathbb{P}_{x_0}(\tau > t) = \int_\Omega dx \ P(x, t \mid x_0) = \sum_{m=1}^\infty e^{-Dt\lambda_m} \ U_m^*(x_0) \int_\Omega dx \ U_m(x),
$$

(1.9)

from which the probability density of the (random) reaction time $\tau$ (i.e. the first-passage time to a reaction event) follows as

$$
\mathbb{E}_{x_0}\{\tau\} = \tilde{S}(0 \mid x_0) = \frac{1}{D} \sum_{m=1}^\infty \lambda_m^{-1} U_m^*(x_0) \int_\Omega dx \ U_m(x),
$$

(1.13)

while its volume average is

$$
\mathbb{E}\{\tau\} = \frac{1}{D |\Omega|} \sum_{m=1}^\infty \lambda_m^{-1} \left| \int_\Omega dx \ U_m(x) \right|^2.
$$

(1.14)
D. S. Grebenkov

Yet another common quantity of interest is the effective diffusion coefficient in a confining domain:

\[ D(t) = \frac{1}{2d} \int_{\Omega} dx_0 \int_{\Omega} dx |x - x_0|^2 P(x, t | x_0) \]

\[ = \frac{1}{2d} \sum_{m=1}^{\infty} e^{-D t \lambda} \int_{\Omega} dx_0 \int_{\Omega} dx |x - x_0|^2 U_m^*(x_0) U_m(x). \] (1.15)

More generally, the \( j \)-point correlation function of the particle position \( X_t \) is

\[ C(t_1, \ldots, t_j | x_0) = \mathbb{E}_{x_0} \{ X_{t_1}, X_{t_2}, \ldots, X_{t_j} \} \]

\[ = \int_{\Omega} dx_1 \ldots \int_{\Omega} dx_j P(x_j, t_j - t_{j-1} | x_{j-1}) x_{j-1} \]

\[ \times \cdots \times P(x_{j-1}, t_{j-1} - t_{j-2} | x_{j-2}) x_{j-2} \cdots \times P(x_1, t_1 | x_0) \]

(with \( 0 < t_1 < \cdots < t_j \)), which can be expressed as the \( j \)-fold spectral sum:

\[ C(t_1, \ldots, t_j | x_0) = \sum_{m_1=1}^{\infty} \cdots \sum_{m_j=1}^{\infty} e^{-D \lambda_{m_1} t_1 - D \lambda_{m_2} t_2 - \cdots - D \lambda_{m_j} (t_j - t_{j-1})} \]

\[ \times U_{m_1}^* (x_0) B_{m_1, m_2} B_{m_2, m_3} \cdots B_{m_{j-1}, m_j} \int_{\Omega} dx_j U_{m_j} (x_j), \] (1.16)

where

\[ B_{m, m'} = \int_{\Omega} dx U_m (x) x U_{m'} (x) \]

(strictly speaking, the above expressions should be written with explicit coordinate components of each point \( x_1, \ldots, x_j \)). To evaluate this multiple sum, one needs to perform \( j \) Laplace transforms, for each time variable \( t_i \):

\[ \mathcal{C}(p_1, \ldots, p_j | x_0) = \sum_{m_1=1}^{\infty} \cdots \sum_{m_j=1}^{\infty} \frac{1}{p_1 + D (\lambda_{m_1} - \lambda_{m_2})} \cdots \frac{1}{p_j + D \lambda_{m_j}} \]

\[ \times U_{m_1}^* (x_0) B_{m_1, m_2} B_{m_2, m_3} \cdots B_{m_{j-1}, m_j} \int_{\Omega} dx_j U_{m_j} (x_j). \] (1.17)

Similar expressions appear in the perturbative expansion of the diffusion NMR signal attenuation in a linear magnetic field gradient \[7, 25, 26\]. As the eigenvalues and eigenfunctions are in general not known, only the asymptotic behavior of spectral sums is usually accessible, e.g., from the Weyl’s asymptotic law for eigenvalues or from the analysis of the heat kernel \[27, 29\].

However, for a limited number of simple domains (see examples in Fig.\[1\]), whose symmetries allow for the separation of variables, the eigenvalues and eigenfunctions are known explicitly \[1, 2\]. An interval, a disk, a circular annulus, a ball and a
A physicist’s guide to explicit summation formulas

Fig. 1. (Color online) Simple domains for which the Laplacian eigenvalues and eigenfunctions involve the zeros of sine, Bessel and spherical Bessel functions and/or their derivatives. For an interval, a disk (a), a circular annulus (b), a ball (d) and a spherical shell (e), many spectral sums can be computed exactly by summation techniques discussed in the review. For a rectangle (c), a right circular cylinder (f), a cylindrical shell (g), and a rectangular cuboid (h), each eigenvalue is the sum of eigenvalues in former basic domains, e.g.,

$$\lambda_{nk} = \frac{\pi^2 n^2}{(b_1 - a_1)^2} + \frac{\pi^2 k^2}{(b_2 - a_2)^2}$$

($k, n = 1, 2, \ldots$) for the rectangle with Dirichlet boundary conditions; as a consequence, spectral sums over double (or triple) indices can be simplified by summation techniques.

Spherical shell are the most studied examples [30] that play the role of important toy models for understanding diffusion-controlled processes, e.g., in chemical physics and biology. The Laplacian eigenfunctions in these basic domains, defined generally as

$$\Omega = \{x \in \mathbb{R}^d : a < |x| < b\}$$

with given radii $0 \leq a < b$, are

$$U_k(r) = A_k \cos(\sqrt{\lambda_k}r) + B_k \sin(\sqrt{\lambda_k}r) \quad (d = 1),$$

$$U_{nk}(r, \phi) = (A_{nk} J_n(\sqrt{\lambda_{nk}}r) + B_{nk} Y_n(\sqrt{\lambda_{nk}}r)) e^{i n \phi} \quad (d = 2),$$

$$U_{nkl}(r, \theta, \phi) = (A_{nk} J_n(\sqrt{\lambda_{nk}}r) + B_{nk} Y_n(\sqrt{\lambda_{nk}}r)) P_l^n(\cos \theta) e^{i l \phi} \quad (d = 3),$$

(1.18)

where $P_l^n(z)$ are the associated Legendre polynomials, $J_n(z)$ and $Y_n(z)$ are the Bessel functions of the first and second kinds, and $j_n(z)$ and $y_n(z)$ are the spherical Bessel functions of the first and second kinds. In two and three dimensions, polar and spherical coordinates are respectively used, while double ($n$ and $k$) and triple ($n, k, l$) indices are employed to enumerate the eigenfunctions and eigenvalues.

As this enumeration is formally equivalent to that by the single index $m$, we will use both schemes and choose one depending on the context. For each eigenfunction $U_k$ (or $U_{nk}$, or $U_{nkl}$), the three unknown parameters, the eigenvalue $\lambda_k$ (or $\lambda_{nk}$) and the coefficients $A_k$ and $B_k$ (or $A_{nk}$ and $B_{nk}$), are determined via one $L_2$ normalization condition,

$$\int_{\Omega} dx |U_m(x)|^2 = 1,$$

(1.19)
and two boundary conditions in Eq. (1.2), written explicitly as

\[(\ell_a \partial_r U_m - U_m)_{r=a} = (\ell_b \partial_r U_m + U_m)_{r=b} = 0, \quad (1.20)\]

with two given constants \(\ell_a\) and \(\ell_b\) (note the sign change in the first relation due to opposite orientation of the radial and normal derivatives). The explicit form of the coefficients \(A_{nk}\) and \(B_{nk}\), as well as an explicit equation determining the eigenvalues \(\lambda_k\) (or \(\lambda_{nk}\)) are well known and will be summarized below. Note that the radial functions in Eq. (1.18) satisfy the radial eigenvalue problem

\[L_d u + \lambda u = 0\]

for the differential operators

\[L_1 = \partial_r^2, \quad L_2 = \partial_r^2 + \frac{1}{r} \partial_r - \frac{n^2}{r^2}, \quad L_3 = \partial_r^2 + \frac{2}{r} \partial_r - \frac{n(n+1)}{r^2}. \quad (1.21)\]

In this review, we discuss three strategies to compute explicitly spectral sums involving the eigenvalues \(\lambda_k\) (or \(\lambda_{nk}\)): (i) representation of meromorphic functions as sums of partial fractions (Sec. 2), (ii) Fourier–Bessel and Dini series (Sec. 3), and (iii) direct evaluation of Laplace-transformed heat kernels (Sec. 4). The first strategy relies on the corollary of the classical Mittag–Leffler theorem from complex analysis that affirms the existence of a meromorphic function with prescribed poles and allows one to express any meromorphic function as a sum of partial fractions. In this way, one aims at identifying an appropriate meromorphic function to represent a given spectral sum. The second strategy is based on the theory of Fourier–Bessel and Dini series that generalize the Fourier series to Bessel functions. Here, one searches for an appropriate function to be decomposed as the Dini series whose form would coincide with the studied spectral sum. The third strategy employs the spectral decomposition (1.5) of the Laplace-transformed heat kernel (or propagator). As the left-hand side can be evaluated independently by solving the modified Helmholtz equation (1.6) in simple domains, one obtains a powerful identity for evaluating spectral sums. Remarkably, even though the eigenvalues usually not known explicitly and require a numerical solution of a transcendental equation, spectral sums like Eq. (1.5) involving such unknown eigenvalues can be often computed exactly and explicitly. Moreover, the particular form (1.15) of the eigenfunctions often enables analytical computation of the integrals in (1.9)–(1.17) (or similar) and thus allows one to derive explicit formulas for such spectral sums.

The ability of computing spectral sums is particularly relevant for understanding the short-time limit of diffusion-controlled quantities. In fact, as each eigenmode in the spectral expansion (1.3) (or similar) is weighted by the exponential factor \(e^{-D\ell\lambda_m}\), more and more terms are needed to determine the behavior of the heat kernel and other quantities in this limit. As a consequence, the analysis is usually performed in the Laplace domain by evaluating the spectral sum (1.5), determining its asymptotic behavior as \(p \to \infty\), and applying Tauberian theorems to get back to the time domain.
At the same time, spectral sums should not be exclusively associated with the short-time limit. For instance, the integral of the heat trace in Eq. (1.7) yields the sum of inverse eigenvalues, which also corresponds to the limit \( p \to 0 \) of Eq. (1.8). In other words, such spectral sums correspond to the long-time limit. For instance, Neuman used the summation formula (2.39) involving the zeros of the derivative of Bessel and spherical Bessel functions to derive the long-time asymptotic behavior of the diffusion NMR signal [31]. This analysis was further extended in [7] (see also more detailed discussions in [8, 32]).

The explicit summation formulas also help simplifying some analytical solutions. For instance, the separation of variables for the diffusion equation in a right circular cylinder, \( \Omega = \{ x \in \mathbb{R}^2 : |x| < R \} \times (a,b) \subset \mathbb{R}^3 \), would naturally lead to double sums over the eigenvalues for an interval \((a,b)\) and the eigenvalues for a disk of radius \( R \) (this is also true for a hollow cylinder when the disk is replaced by an annulus). In some cases, one of these sums can be calculated explicitly, thus simplifying expressions and speeding up numerical computations (see an example in [33]). The same argument is applicable to rectangles and rectangular cuboids: \((a_1,b_1) \times (a_2,b_2) \times \cdots \times (a_d,b_d) \subset \mathbb{R}^d\). For instance, summation formulas were intensively employed to study first-passage times for two particles with reversible target-binding kinetics in a one-dimensional setting, which can be mapped onto diffusion in a rectangle [34]. Similarly, the statistics of encounters of two independent particles diffusing on an interval can be investigated in this way [35].

Rather than dwelling on mathematical proofs and technicalities, our goal is to provide an intuitive practical guide over powerful analytical tools for evaluating spectral sums that could be accessible to non-experts. While many common summation formulas often appearing in applications are summarized, the review does not pretend to be exhaustive.

2. Expansion of Meromorphic Functions

The first strategy for evaluating spectral sums is based on the corollary of the Mittag-Leffler theorem from complex analysis [36]. This classical theorem describes the properties of meromorphic functions, i.e. functions which are holomorphic (or analytic) at all points except for a discrete set of isolated points (their poles). Any meromorphic function \( F(z) \) can be represented as a ratio of two holomorphic functions, \( F(z) = f(z)/g(z) \), so that the poles of \( F(z) \) are just the zeros of \( g(z) \). While the general theory refers to an open subset of the complex plane \( \mathbb{C} \), we restrict discussion to meromorphic functions in \( \mathbb{C} \), in which case the holomorphic functions are called entire functions (i.e. they can be represented by power series uniformly converging on compact sets). Polynomials, exponential function, sine and cosine, Bessel functions \( J_n(z) \) of the first kind of an integer order \( n \), spherical Bessel functions \( j_n(z) \) of the first kind of an integer order \( n \), their finite sums, products and compositions, derivatives and integrals are examples of entire functions. In contrast, square root, logarithm and functions with essential singularities (e.g., \( e^{1/z} \)) are not
entire functions. The Mittag-Leffler theorem claims the existence of a meromorphic function with prescribed poles. As a consequence, any meromorphic function can be decomposed as a sum of partial fractions.

In this light, a meromorphic function is a natural extension of rational functions (i.e. ratio of two polynomials). Any rational function can be decomposed into a sum of partial fractions, e.g.,

$$\frac{(z - 1)^4}{z^4(z + 1)} = z - 5 - \frac{5}{z} + \frac{16}{z^2} + \frac{2}{z + 1} = z - 5 + \sum_{k=1}^{2} \sum_{j=1}^{n_k} \frac{c_{k,j}}{(z - z_k)^j}, \quad (2.1)$$

with the regular part $z - 5$, the poles $z_1 = 0$ and $z_2 = -1$ of order $n_1 = 2$ and $n_2 = 1$, and the weights $c_{1,1} = -5$, $c_{1,2} = 1$ and $c_{2,1} = 16$. The Mittag-Leffler theorem extends such decompositions to meromorphic functions [36, p. 297]: any meromorphic function $F(z)$ with a prescribed sequence of poles \{\(z_k\}\} (with orders $n_k$) can be represented as

$$F(z) = \frac{F_0(z)}{\text{regular part}} + \sum_k \left[ \sum_{j=1}^{n_k} \frac{c_{k,j}}{(z - z_k)^j} + \frac{P_k(z)}{(z - z_k)^{j+1}} \right], \quad (2.2)$$

where the regular part $F_0(z)$ is an entire function, each principal part is the sum of the principal parts near the pole $z_k$ with weights $c_{k,j}$, and $P_k(z)$ are polynomials. The theorem states that a meromorphic function is essentially determined by its principal parts, up to an entire function. Since a meromorphic function may have infinite number of poles (i.e. the sum over $k$ can be infinite), adding polynomials $P_k(z)$ to the principal parts in the right-hand side of Eq. (2.2) may be needed to ensure the convergence of the series. For instance, the decomposition of the meromorphic function in Eq. (2.1) includes the entire function $F_0(z) = z - 5$ and two principal parts.

The strategy for computing spectral sums consists in finding (or guessing) an appropriate meromorphic function. Let us first consider spectral sums that can be reduced to

$$F(z) = \sum_k \frac{e_k}{z - z_k}, \quad (2.3)$$

with a prescribed set of simple poles $\{z_k\}$ (i.e. $n_k = 1$) and coefficients $\{e_k\}$. In the first step, one searches for an entire function $g(z)$ whose complete set of zeros is the set $\{z_k\}$. In practice, this is a simple step because the eigenvalues are often expressed in terms of zeros of some explicit entire functions. Next, one searches for another entire function $f(z)$ such that $f(z_k) \neq 0$ for all $k$, and $F(z) = f(z)/g(z)$. The zeros $\{z_k\}$ are therefore the poles of the meromorphic function $F(z) = f(z)/g(z)$. Around $z \approx z_k$, one has $g(z) = g'(z_k)(z - z_k) + O((z - z_k)^2)$, from which

$$F(z) = \frac{f(z)}{g(z)} = \frac{f(z_k)}{g'(z_k)(z - z_k)} + \text{regular part} \quad (z \to z_k), \quad (2.4)$$
A physicist’s guide to explicit summation formulas

where the prime denotes the derivative with respect to the argument of the function. The first term in (2.3) is the principal part of the function \( F(z) \). The function \( f(z) \) should satisfy \( f(z_k)/g'(z_k) = e_k \) for each \( k \). Applying the corollary of the Mittag-Leffler theorem, one has

\[
\frac{f(z)}{g(z)} = F(z) = F_0(z) + \sum_k \left[ \frac{f(z_k)}{g'(z_k)} \frac{1}{z - z_k} + P_k(z) \right],
\]

(2.5)

where an entire function \( F_0(z) \) (accounting for remaining regular parts) and polynomials \( P_k(z) \) (ensuring the convergence) have to be found. In many cases, the “indefinite” ingredients \( F_0(z) \) and \( P_k(z) \) can be guessed or computed. A practical strategy may consist in computing numerically the truncated series in the right-hand side and checking this relation (paying attention to the convergence which may be critical for numerical analysis).

In the general case when a pole \( z_k \) has the order \( n_k \), the series expansion around \( z \approx z_k \) reads

\[
F(z) = \frac{f(z)}{g(z)} = \frac{b_0 + b_1(z - z_k) + b_2(z - z_k)^2 + \cdots}{(z - z_k)^{n_k}(a_0 + a_1(z - z_k) + a_2(z - z_k)^2 + \cdots)}
\]

\[
= \frac{1}{(z - z_k)^{n_k}} \sum_{m=0}^{\infty} c_m (z - z_k)^m
\]

\[
= \sum_{m=0}^{n_k-1} \frac{c_m}{(z - z_k)^{n_k-m}} + \text{regular part},
\]

(2.6)

where

\[
c_m = \frac{1}{a_0^{n_k+1}} \sum_{i_0 + \cdots + i_m + j = m} (-1)^{i_0} b_j a_0^{i_0} a_1^{i_1} \cdots a_m^{i_m},
\]

(2.7)

and the indices \( i_0, \ldots, i_m, j \) are non-negative. For instance, one has

\[
c_0 = \frac{b_0}{a_0}, \quad c_1 = \frac{b_0 a_1 - b_1 a_0}{a_0^2}, \quad c_2 = \frac{b_0 a_1^2 + b_2 a_0^2 - b_1 a_1 a_0 - b_0 a_2 a_0}{a_0^3}, \ldots.
\]

The coefficients \( a_m \) and \( b_m \) are related to the derivatives of the functions \( f(z) \) and \( g(z) \) at points \( z_k \):

\[
a_m = \frac{1}{(m + n_k)!} \left( \frac{d^{m+n_k} g(z)}{dz^{m+n_k}} \right)_{z=z_k}, \quad b_m = \frac{1}{m!} \left( \frac{d^m f(z)}{dz^m} \right)_{z=z_k}.
\]

(2.8)

In the particular case \( e_k = n_k \), one formally gets an expansion of the logarithmic derivative of \( g(z) \):

\[
\frac{g'(z)}{g(z)} = \sum_k \frac{n_k}{z - z_k}.
\]

(2.9)
In a typical case of an infinite sequence of simple zeros (i.e. \(n_k = 1\)),\(^a\) this relation can be made rigorous by requiring

\[
\lim_{k \to \infty} |z_k| = \infty \quad \text{and} \quad \sum_{k} \frac{1}{|z_k|} = \infty.
\]

The relation (2.10) can be formally obtained by representing \(g(z)\) as a product over its zeros,

\[
g(z) = g_0 \prod_{k} (z - z_k)^{n_k}
\]

(with a constant \(g_0\)), taking derivative and dividing it by \(g(z)\).

### 2.1. Basic example: Interval with absorbing endpoints

To illustrate this strategy, let us compute the Laplace-transformed heat trace \(\tilde{Z}(p)\) in the simple case of the Laplace operator on the interval of length \(R\) with Dirichlet boundary conditions at both endpoints (\(\ell = 0\)), for which \(\lambda_m = \pi^2 m^2 / R^2\) (with \(m = 1, 2, 3, \ldots\)):

\[
\tilde{Z}(p) = \frac{R^2}{2zD} \left( \frac{1}{z} - \sum_{k=-\infty}^{\infty} \frac{1}{z - \pi k} \right),
\]

where we set \(-z^2 = pR^2/D\). One needs therefore to compute the last sum with simple poles at \(z_k = \pi k\) that are all the zeros of the entire function \(g(z) = \sin z\). Applying Eq. (2.9), one gets

\[
\cos z \sin z = \sum_{k=-\infty}^{\infty} \frac{1}{z - \pi k},
\]

which is still formal because the series in the right-hand side is divergent. To regularize this series, one can subtract \(1/\pi k\) (for \(k \neq 0\)) whose contribution would be canceled anyway due to the similar term for \(-k\):

\[
\frac{\cos z}{\sin z} - \frac{1}{z} = \sum_{k=-\infty \text{ or } k \neq 0}^{\infty} \left( \frac{1}{z - \pi k} - \frac{1}{\pi k} \right),
\]

\(^a\)This mathematical result can be significantly extended as described by [36]. Here we do not discuss convergence of the series in the right-hand side of Eq. (2.9), especially since the most attention will be focused on the function \(\eta_n(z)\) defined by the convergent series in Eq. (2.22).
where the term with $k = 0$ was moved to the left-hand side. The subtracted term $1/\pi k$ is precisely the polynomial $P_k(z)$ (here, just a constant) in the general representation (2.2). As the series in Eq. (2.11) is convergent, this regularization is actually not needed, and the substitution of Eq. (2.12) into Eq. (2.11) yields two equivalent classical summation formulas

$$\sum_{k=1}^{\infty} \frac{1}{z^2 - \pi^2 k^2} = \frac{\cos z}{2z \sin z} - \frac{1}{2z^2},$$  
(2.13a)
$$\sum_{k=1}^{\infty} \frac{1}{z^2 + \pi^2 k^2} = \frac{\cosh z}{2z \sinh z} - \frac{1}{2z^2},$$  
(2.13b)

from which

$$\tilde{Z}(p) = \frac{R \cosh(R\sqrt{p/D})}{2\sqrt{pD} \sinh(R\sqrt{p/D})} - \frac{1}{2p}. \tag{2.14}$$

A similar derivation with the function $f(z) = 1$ in (2.5) yields

$$\sum_{k=1}^{\infty} (-1)^k \frac{1}{z^2 - \pi^2 k^2} = \frac{1}{2z \sin z} - \frac{1}{2z^2}, \tag{2.15a}$$
$$\sum_{k=1}^{\infty} (-1)^k \frac{1}{z^2 + \pi^2 k^2} = \frac{1}{2z \sinh z} - \frac{1}{2z^2}. \tag{2.15b}$$

The explicit form (2.14) of the Laplace-transformed heat trace $\tilde{Z}(p)$ facilitates the analysis of the short-time and long-time asymptotic behaviors of the return-to-the-origin probability discussed in Sec. 1. The knowledge of $\tilde{Z}(p)$ also allows one to compute some other spectral series, in particular,

$$\sum_{m=1}^{\infty} \frac{1}{\lambda_{m+1}^n} = \frac{(-1)^n D^{n+1}}{n!} \lim_{p \to 0} \left( \frac{\partial^n}{\partial p^n} \tilde{Z}(p) \right) \quad (n = 0, 1, \ldots). \tag{2.16}$$

For example, one easily retrieves the even integer values of the Riemann zeta-function,

$$\zeta(z) = \sum_{m=1}^{\infty} \frac{1}{m^z}, \tag{2.17}$$

as

$$\zeta(2n) = \frac{\pi^{2n}}{2^{n-1}(n-1)!} \lim_{s \to 0} \frac{d^{n-1}}{ds^{n-1}} \left( \frac{\cosh(\sqrt{s})}{2\sqrt{s} \sinh(\sqrt{s})} - \frac{1}{s} \right) \quad (n = 1, 2, \ldots), \tag{2.18}$$

for instance

$$\zeta(2) = \frac{\pi^2}{6}, \quad \zeta(4) = \frac{\pi^4}{90}, \ldots. \tag{2.19}$$

As shown below, many other spectral series can be reduced to (2.14). While the same technique is applicable to a more general case of an interval with partially absorbing endpoints ($\ell > 0$), we will discuss this case in Sec. 4.
2.2. Disk and ball

In the case of a disk or a ball of radius $R$, the separation of variables in polar or spherical coordinates leads again to an explicit form of the eigenfunctions of the Laplace operator. The eigenvalues $\lambda_n$ can be written as $\alpha^2_{nk}/R^2$ with double indices $n = 0, 1, 2, \ldots$ and $k = 1, 2, \ldots$, where $\alpha_{nk}$ are strictly positive simple zeros of an explicit entire function:

$$g_n(z) = \begin{cases} z J_n^2(z) + h J_n(z) & (d = 2), \\ z j_n^2(z) + h j_n(z) & (d = 3), \end{cases} \quad (2.20)$$

where $h = R/\ell$ is a non-negative parameter (see Table 1). In this case, the computation should be performed separately for each $n$. Note that the zero eigenvalue appears only for the Neumann boundary condition and will be treated separately.

To illustrate this technique, we focus on computing the Laplace-transformed heat kernel trace $\tilde{Z}(p)$, while more sophisticated summation formulas will be reported in Sec. 3 (see also Table 3). For convenience, we rewrite $\tilde{Z}(p)$ as

$$\tilde{Z}(p) = -\frac{R^2}{D} \sum_n \sum_{k=1}^{\infty} \frac{1}{-R^2 p/D - \alpha^2_{nk}} = -\frac{R^2}{D} \sum_n \eta_n(i R \sqrt{p/D}), \quad (2.21)$$

where

$$\eta_n(z) = \sum_{k=1}^{\infty} \frac{1}{z^2 - \alpha^2_{nk}} = \frac{1}{2z} \sum_{k=1}^{\infty} \left( \frac{1}{z - \alpha_{nk}} + \frac{1}{z + \alpha_{nk}} \right), \quad (2.22)$$

and $z = R \sqrt{p/D}$. According to the form (2.18) of Laplacian eigenfunctions, the function $\eta_n(z)$ can be associated with the $n$th Fourier (or spherical harmonic) mode. Note that $\{-\alpha_{nk}\}$ are also zeros of the function $g_n(z)$ due to its symmetry. Moreover, the function $g_n(z)$ vanishes at $z = 0$ for any $n > 0$ but also for $n = 0$ in the case of Neumann boundary condition. Since the set $\{0, \pm \alpha_{nk}\}$ contains all zeros of $g_n(z)$, one can apply the corollary of the Mittag-Leffler theorem to get

$$\eta_n(z) = \frac{1}{2z} \frac{g_n'(z)}{g_n(z)} - \frac{n}{2z^2} \quad (n > 0), \quad (2.23)$$

where the second term accounts for the zero at 0, which is excluded from $\eta_n(z)$. For the Neumann boundary condition, $z = 0$ is also a simple zero of $g_0(z)$, and as it was accounted twice, it should be subtracted:

$$\eta_0(z) = \frac{1}{2z} \frac{g_0'(z)}{g_0(z)} - \frac{1}{2z^2}. \quad (2.24)$$

Note that the condition (2.11) is satisfied thanks to the asymptotic behavior $\alpha_{nk} \propto k$ (for fixed $n$). As shown in (2.22), $\eta_n(z)$ from (2.23) with $n > 0$ can also be written for a ball in any dimension and boundary condition as

$$\eta_n(z) = \frac{(h - n - d + 2) - \left[ z^2 + (2n + d - 2)(h - n - d + 2) \right] \psi_{n,d}(z)}{2z^2 \left[ 1 + (h - n - d + 2) \psi_{n,d}(z) \right]}, \quad (2.25)$$
where the function \( \psi_{n,d}(z) \) is defined by the recurrent relation
\[
\psi_{n+1,d}(z) = \frac{2n + d - 2}{z^2} \frac{1}{\psi_{n,d}(z)} \quad (n \geq 1),
\]
(2.26)
and
\[
\psi_{1,d}(z) = \begin{cases} 
\frac{\sin z}{z \cos z} & (d = 1), \\
\frac{J_{1}(z)}{z J_{0}(z)} & (d = 2), \\
\frac{j_{1}(z)}{z j_{0}(z)} & (d = 3).
\end{cases}
\]
(2.27)

Note that the above representation with \( d = 1 \) is also valid for a symmetric interval \((-R, R)\); see details in [32].

As an example, let us consider a disk with Dirichlet boundary condition \((\ell = 0)\), for which Eq. (2.23) implies the summation formula:
\[
\sum_{k=1}^{\infty} \frac{1}{z^2 - \alpha_{nk}^2} = \frac{1}{2z} \frac{J_{\ell}'(z)}{J_{\ell}(z)} = -\frac{1}{2z} \frac{J_{\ell+1}(z)}{J_{\ell}(z)}.
\]
(2.28)
This is a particular case of the summation formula (see [37, p. 498])
\[
\frac{J_{\nu+1}(z)}{J_{\nu}(z)} = \sum_{k=1}^{\infty} \frac{2z}{\alpha_{nk}^2 - z^2} \quad (\nu > -1),
\]
(2.29)
where \( \pm \alpha_{nk} \) are zeros of \( z^{-\nu}J_{\nu}(z) \). Evaluating the derivatives of this identity at \( z = 0 \), Rayleigh found other summation formulas [38], e.g.,
\[
\sum_{k=1}^{\infty} \frac{1}{\alpha_{nk}^2} = \frac{1}{2^2(\nu + 1)} \quad \sum_{k=1}^{\infty} \frac{1}{\alpha_{nk}^4} = \frac{1}{2^4(\nu + 1)^2(\nu + 2)} \ldots
\]
(2.30)
(see also [37], [39], [40]). At \( \nu = 1/2 \), \( z^{-\nu}J_{\nu}(z) = \sqrt{2\pi} \frac{\sin z}{z^2} \) so that Eqs. (2.29) and (2.30) are reduced to Eqs. (2.11) and (2.19) for the interval. Similarly, one gets a representation of the inverse of the Bessel function as
\[
\frac{1}{J_{n}(z)} = \mathcal{P}_{n}(1/z) + \begin{cases} 
2z \sum_{k=1}^{\infty} \frac{J_{n}'(\alpha_{nk})(z^2 - \alpha_{nk}^2)}{\mathcal{P}_{n}(\alpha_{nk})} & (n \text{ is odd}), \\
2z \sum_{k=1}^{\infty} \frac{\alpha_{nk}}{J_{n}'(\alpha_{nk})(z^2 - \alpha_{nk}^2)} & (n \text{ is even}),
\end{cases}
\]
(2.31)
where \( \mathcal{P}_{n} \) is the polynomial of degree \( n \) that accounts for the pole at 0:
\[
\mathcal{P}_{0}(x) = 0, \quad \mathcal{P}_{1}(x) = 2x, \quad \mathcal{P}_{2}(x) = 8x^2, \quad \mathcal{P}_{3}(x) = 3x + 48x^3, \ldots
\]
(2.32)
The explicit form of this polynomial can be obtained by expanding \( z^n/J_{n}(z) \) in a Taylor series around 0 and keeping the terms up to the \( n \)th order.
Once \( \eta_n(z) \) is known, one can establish a number of useful relations for more complicated sums involving the Laplacian eigenvalues. Such spectral sums naturally appear when the quantity of interest depends on several time variables, \( t_1, \ldots, t_j \), as, e.g., the \( j \)-point correlation function in (1.16). In this case, the Laplace transform is applied to each time variable, and the Laplace-transformed quantity in (1.17) depends on multiple conjugate parameters \( p_1, \ldots, p_j \). First, one can compute the sums

\[
\eta_n^{(j)}(z_1, \ldots, z_j) = \sum_{k=1}^{\infty} \prod_{i=1}^{j} \frac{1}{z_i^2 - \alpha_{nk}^2} \tag{2.33}
\]

iteratively, applying the identity

\[
\eta_n^{(j)}(z_1, \ldots, z_j) = \frac{\eta_n^{(j-1)}(z_1, \ldots, z_{j-2}, z_{j-1}) - \eta_n^{(j-1)}(z_1, \ldots, z_{j-2}, z_j)}{z_j^2 - z_{j-1}^2}, \tag{2.34}
\]

with \( \eta_n^{(1)}(z) \equiv \eta_n(z) \). In particular,

\[
\eta_n^{(2)}(z_1, z_2) = \frac{\eta_n(z_1) - \eta_n(z_2)}{z_2 - z_1}, \tag{2.35}
\]

\[
\eta_n^{(3)}(z_1, z_2, z_3) = \frac{1}{z_3^2 - z_2^2} \left( \frac{\eta_n(z_1) - \eta_n(z_2)}{z_2^2 - z_1^2} - \frac{\eta_n(z_1) - \eta_n(z_3)}{z_3^2 - z_1^2} \right), \tag{2.36}
\]

\[
\eta_n^{(4)}(z_1, z_2, z_3, z_4) = \frac{1}{z_4^2 - z_3^2} \left( \frac{1}{z_3^2 - z_2^2} \left[ \frac{\eta_n(z_1) - \eta_n(z_2)}{z_2^2 - z_1^2} - \frac{\eta_n(z_1) - \eta_n(z_3)}{z_3^2 - z_1^2} \right] \right) \tag{2.37}
\]

Multiple differentiation of Eq. (2.33) with respect to the variables \( s_i = z_i^2 \) further extends the set of useful relations for any positive integers \( \sigma_1, \ldots, \sigma_j \):

\[
\sum_{k=1}^{\infty} \prod_{i=1}^{j} \frac{1}{(s_i - \alpha_{nk}^2)^{\sigma_i+1}} = \frac{(-1)^{\sigma_1 + \cdots + \sigma_j}}{\sigma_1! \cdots \sigma_j!} \frac{\partial^{\sigma_1 + \cdots + \sigma_j}}{\partial s_1^{\sigma_1} \cdots \partial s_j^{\sigma_j}} \eta_n^{(j)}(\sqrt{s_1}, \ldots, \sqrt{s_j}). \tag{2.38}
\]

For instance, for \( j = 1 \) and \( \sigma = 0, 1, 2, \ldots \), one gets

\[
\sum_{k=1}^{\infty} \frac{1}{(s - \alpha_{nk}^2)^{\sigma+1}} = \frac{(-1)^{\sigma}}{\sigma!} \frac{\partial^{\sigma} \eta_n(\sqrt{s})}{\partial s^{\sigma}}, \tag{2.39}
\]

from which the sum of inverse powers of eigenvalues (as in Eq. (2.30)) can be evaluated by setting \( z \to 0 \) (or \( s \to 0 \)). For example, setting \( \sigma = 0 \), one retrieves (see, e.g., [42] and references therein):

\[
\sum_{k=1}^{\infty} \frac{1}{\alpha_{nk}^n} = \frac{n + h + 2}{4(n + 1)(n + h)}. \tag{2.40}
\]

Although cumbersome, these expressions allow one to rigorously compute many spectral sums and related quantities involving the Laplacian eigenvalues (see [32] for examples and applications).
As an example, we discuss Calogero’s formula for the zeros $\alpha_{nk}$ of the function $g_n(z) = zJ'_n(z) + hJ_n(z)$ with any real $\nu > -1$ \[13\] \[44\]

\[
\sum_{k \neq j} \frac{1}{\alpha_{nj}^2 - \alpha_{nk}^2} = \frac{1}{2(\alpha_{nj}^2 + h^2 - \nu^2)} - \frac{\nu + 1}{2\alpha_{nj}^2} \tag{2.41}
\]

This formula can be easily derived for integer $\nu = n$ by evaluating the limit:

\[
\sum_{k \neq j} \frac{1}{\alpha_{nj}^2 - \alpha_{nk}^2} = \lim_{\varepsilon \to 0} \left( \eta_n(\alpha_{nj} + \varepsilon) - \frac{1}{(\alpha_{nj} + \varepsilon)^2 - \alpha_{nk}^2} \right). \tag{2.42}
\]

Using the explicit form \[2.23\] of the function $\eta_n(z)$, one can compute the limit by expanding $g_n(z)$ and $g''_n(z)$ in a Taylor series around $z = \alpha_{nj}$. After simplifications, one gets

\[
\sum_{k \neq j} \frac{1}{\alpha_{nj}^2 - \alpha_{nk}^2} = \frac{g''_n(\alpha_{nj})}{4\alpha_{nj}g'_n(\alpha_{nj})} - \frac{n + 1/2}{2\alpha_{nj}^2}. \tag{2.43}
\]

Using the Bessel equation,

\[z^2 J''_n(z) + z J'_n(z) + (z^2 - n^2)J_n(z) = 0,\]

one can express in two dimensions

\[
g'_n(z) = hJ'_n(z) + \frac{n^2 - z^2}{z}J_n(z), \tag{2.44}
\]

\[
g''_n(z) = \frac{n^2 - z^2 - h}{z}J'_n(z) + \frac{h(n^2 - z^2)}{z^2} - \frac{n^2 - z^2}{z}J_n(z). \tag{2.45}
\]

Since $\alpha_{nj}$ is a zero of $g_n(z)$, one finally gets

\[
\frac{g''_n(\alpha_{nj})}{g'_n(\alpha_{nj})} = \frac{\alpha_{nj}^2 + n^2 - h^2}{\alpha_{nj}(\alpha_{nj}^2 + h^2 - n^2)}. \tag{2.46}
\]

from which Calogero’s formula \[2.41\] follows for an integer $\nu = n$. Similarly, one can deduce the summation formulas for higher-order inverse differences between eigenvalues, see \[12\] \[45\] \[47\]. Interestingly, Calogero and his co-workers considered \[2.41\] as an infinite system of nonlinear equations that determines the zeros $\alpha_{nk}$, together with the normalization relation \[2.30\] extended to non-integer $\nu$.

In three dimensions, one uses the modified Bessel equation to express

\[
g'_n(z) = (h - 1)J'_n(z) + \frac{n(n + 1) - z^2}{z}j_n(z), \tag{2.47}
\]

\[
g''_n(z) = n(n + 1) - z^2 - 2(h - 1)j'_n(z) + \frac{(h - 2)n(n + 1) - h^2}{z^2}j_n(z), \tag{2.48}
\]
from which
\[ \frac{g''_n(\alpha_{nj})}{g'_n(\alpha_{nj})} = 2 \frac{n(n + 1) - h(h - 1)}{\alpha_{nj}(\alpha_{nj}^2 + h(h - 1) - n(n + 1))}, \]  
and thus
\[ \sum_{k=1; k \neq j}^{\infty} \frac{1}{\alpha_{nj}^2 - \alpha_{nk}^2} = \frac{1}{2} \frac{2(\alpha_{nj}^2 + h(h - 1) - n(n + 1))}{2\alpha_{nj}} - \frac{n + 3/2}{2n}. \]  
This is an extension of Calogero’s formula to the zeros \( \alpha_{nk} \) of the function \( g_n(z) = zJ_{\nu}(z) + hj_{\nu}(z) \) involving spherical Bessel function and its derivative.

As the review is focused on the eigenvalues of the Laplace operator in rotation-invariant domains (here, a disk or a ball), we restricted the discussion to Bessel functions. The Fourier–Bessel series involve the zeros of a Bessel function
\[ \alpha_{nk} \]
and thus
\[ \sum_{k=1; k \neq j}^{\infty} \frac{1}{\alpha_{nj}^2 - \alpha_{nk}^2} = \frac{1}{2} \frac{2(\alpha_{nj}^2 + h(h - 1) - n(n + 1))}{2\alpha_{nj}} - \frac{n + 3/2}{2n}. \]  
This is an extension of Calogero’s formula to the zeros \( \alpha_{nk} \) of the function \( g_n(z) = zJ_{\nu}(z) + hj_{\nu}(z) \) involving spherical Bessel function and its derivative.

Table 1. Laplacian eigenfunctions and eigenvalues in a disk and a ball of radius \( R \).

We recall that \( J_\nu(z) \) and \( j_\nu(z) \) are the Bessel and spherical Bessel functions of the first kind, \( P_\nu(z) \) are the associated Legendre polynomials, and \( h = R/\ell \). Here \( \alpha_{nk} \) are all strictly positive zeros of the function \( g_\nu(z) \), enumerated by \( k = 1, 2, 3, \ldots \), except for the Neumann boundary condition \( \beta = 0 \) for which \( \alpha_{01} = 0 \) and \( \beta_{01} = 1 \) for the disk, as well as \( \alpha_{01} = 0 \) and \( \beta_{01} = \sqrt{\nu^2/2} \) for the ball. Note that the eigenfunctions for the disk are often written in the real-valued form, in which \( e^{in\phi} \) is replaced by \( \cos(n\phi) \) and \( \sin(n\phi) \) with \( n = 0, 1, 2, \ldots \).

| Domain | Disk | Ball |

- the Dini expansion (for \( \nu \geq -1/2 \) and \( \nu + h > 0 \))

\[
f(x) = 2 \sum_{k=1}^{\infty} \frac{J_\nu(\alpha_{vk} x)}{J_\nu^2(\alpha_{vk})} \frac{\alpha_{vk}^2}{\alpha_{vk} - \nu^2 - h^2} \int_0^1 dy f(y) J_\nu(\alpha_{vk} y),
\]

(3.3)

where \( \alpha_{vk} \) are the positive zeros of \( z J'_\nu(z) + h J_\nu(z) \) (Robin case).

Note that the continuity assumption and some other constraints can be weakened (see details in [37]). If the Fourier series can be seen as spectral expansions on Laplacian eigenfunctions on an interval, the Fourier–Bessel and Dini series are essentially the spectral expansions over radial parts of the Laplacian eigenfunctions on the disk (see also Sec. 3).

As pointed out by Watson [37], the coefficients of these expansions, given by integrals with the function \( f(y) \), are rarely known explicitly. Among such examples, one has

\[
x' = \sum_{k=1}^{\infty} \frac{2 J_\nu(\alpha_{vk} x)}{\alpha_{vk} J_{\nu+1}(\alpha_{vk})} \left( 0 \leq x < 1 \right)
\]

(3.4)

for \( \alpha_{vk} \) being zeros of \( J_\nu(z) \), and

\[
x' = \sum_{k=1}^{\infty} \frac{2 \alpha_{vk} J_{\nu+1}(\alpha_{vk}) J_\nu(\alpha_{vk} x)}{(\alpha_{vk}^2 - \nu^2 - h^2)[J_\nu(\alpha_{vk})]^2} \left( 0 \leq x < 1 \right)
\]

(3.5)
D. S. Grebenkov

for $\alpha_{nk}$ being zeros of $zJ'_\nu(z) + \nu J_\nu(z)$ (under the additional condition $\nu + h > 0$).

Relying on these expansions, Sneddon derived the following summation formulas for some positive integer $m$ [39].

- Dirichlet case when $\alpha_{nk}$ are positive zeros of $J_\nu(z)$:

$$\sum_{k=1}^{\infty} \frac{1}{\alpha_{nk}^m} = \begin{cases} \frac{1}{4(\nu+1)} & (m = 1), \\ \frac{1}{16(\nu+1)^2(\nu+2)} & (m = 2), \\ \frac{1}{32(\nu+1)^4(\nu+2)(\nu+3)} & (m = 3), \\ \frac{5\nu+11}{256(\nu+1)^4(\nu+2)^2(\nu+3)(\nu+4)} & (m = 4) \end{cases}$$

and

$$\sum_{k=1}^{\infty} \frac{1}{\alpha_{nk}^{2m-\nu+1} J_{\nu+1}(\alpha_{nk})} = \begin{cases} \frac{2\nu^3 \Gamma(\nu+1)}{(\nu+1)} & (m = 1), \\ \frac{2\nu^6(\nu+3)\Gamma(\nu+1)}{(\nu+1)^2(\nu+2)} & (m = 2), \\ \frac{2\nu^8(\nu^2+8\nu+19)\Gamma(\nu+1)}{3(\nu+1)^3(\nu+2)(\nu+3)} & (m = 3), \end{cases}$$

(note that (3.6) reproduces Rayleigh’s formulas (2.30)).

- Neumann case when $\alpha_{nk}$ are positive zeros of $J'_\nu(z)$:

$$\sum_{k=1}^{\infty} \frac{1}{\alpha_{nk}^{2m}(\alpha_{nk}^2 - \nu^2)} = \begin{cases} \frac{3\nu + 4}{16\nu^2(\nu+1)^2(\nu+2)} & (m = 1), \\ \frac{5\nu^2 + 16\nu + 12}{32\nu^4(\nu+1)^2(\nu+2)(\nu+3)} & (m = 2), \\ \frac{35\nu^4 + 273\nu^3 + 768\nu^2 + 896\nu + 392}{256\nu^6(\nu+1)^4(\nu+2)(\nu+3)(\nu+4)} & (m = 3), \end{cases}$$

and

$$\sum_{k=1}^{\infty} \frac{1}{\alpha_{nk}^{2m-2\nu} J_{\nu}(\alpha_{nk})} = \begin{cases} \frac{8\nu(\nu+1)}{\nu^2 + 7\nu + 8} & (m = 1), \\ \frac{64\nu^2(\nu+1)^2(\nu+2)}{\nu^4 + 14\nu^3 + 91\nu^2 + 210\nu + 144} & (m = 2), \\ \frac{768\nu^2(\nu+1)^3(\nu+2)(\nu+3)}{768\nu^2(\nu+1)^4(\nu+2)^2(\nu+3)(\nu+4)} & (m = 3). \end{cases}$$
A physicist’s guide to explicit summation formulas

- Robin case when \( \alpha_{\nu k} \) are positive zeros of \( zJ'_{\nu}(z) + hJ_{\nu}(z) \):

\[
\sum_{k=1}^{\infty} \frac{1}{\alpha_{\nu k}^2 (\alpha_{\nu k}^2 - \nu^2 + h^2)} = \begin{cases} 
\frac{1}{2(h + \nu)} & (m = 0), \\
\frac{1}{4(h + \nu)^2 (\nu + 1)} & (m = 1), \\
\frac{h + 3\nu + 4}{16(h + \nu)^3 (\nu + 1)^2 (\nu + 2)} & (m = 2), \\
h^2 + 2(2\nu + 3)h + 5\nu^2 + 16
\nu + 2
& 32(h + \nu)^4 (\nu + 1)^3 (\nu + 2)(\nu + 3) & (m = 3).
\end{cases}
\]

(3.10)

Note that the Sneddon’s technique can be used to derive such formulas for larger values of \( m \).

Sneddon also gave some examples of other series, e.g.,

\[
\sum_{k=1}^{\infty} \frac{\sin \alpha_{0k}}{\alpha_{0k}^2} J_1(\alpha_{0k}) = \frac{1}{2}, \\
\sum_{k=1}^{\infty} \frac{\sin \alpha_{0k}}{\alpha_{0k}^3} J_2(\alpha_{0k}) = \frac{1}{2} - \ln 2
\]

(3.11)

for the Dirichlet case, and

\[
\sum_{k=1}^{\infty} \frac{\sin \alpha_{0k}}{\alpha_{0k}^2 + h^2} J_0(\alpha_{0k}) = \frac{1}{2h}
\]

(3.12)

for the Robin case.

In summary, Fourier–Bessel and Dini series present a powerful tool for deriving spectral sums over the zeros of Bessel functions. However, as such series involve only Bessel functions of the first kind, \( J_\nu(z) \), they are not directly applicable to circular annuli or spherical shells, for which the Laplacian eigenfunctions also include Bessel functions of the second kind, \( Y_\nu(z) \). In the next section, we discuss a different method based on the direct computation of the Laplace-transformed heat kernel. Here, the radial coordinate will be restricted on an interval \((a, b)\), and the Sturm–Liouville theory will ensure the completeness of a basis formed by linear combinations of \( J_\nu(z) \) and \( Y_\nu(z) \).

4. Laplace-Transformed Heat Kernel

The two strategies discussed in the previous sections are well adapted for evaluating spectral sums involving the eigenvalues of the Laplace operator on an interval, a disk, and a ball. In particular, the associated eigenfunctions are expressed through entire functions: sine, cosine, Bessel and spherical Bessel functions of the first kind. However, these strategies are not suitable for circular annuli and spherical shells because Bessel and spherical Bessel functions of the second kind, \( Y_\nu(z) \) and \( y_\nu(z) \), are not entire functions. Similarly, the Fourier–Bessel and Dini series do not operate with \( Y_\nu(z) \) and \( y_\nu(z) \). For this reason, we discuss here in more detail the third
strategy for evaluating spectral sums that is also applicable to the Laplace operator in circular annuli and spherical shells. In these rotation-invariant domains, the separation of variables reduces the computation of the Laplacian eigenvalues to the analysis of radial second-order differential operators \( L_d \) in Eq. (1.21).

### 4.1. General case

Let us first recall the basic elements of the Sturm–Liouville theory that can be found in most textbooks on differential equations and mathematical physics, e.g., [48, 49]. Let \( \mathcal{L} \) be a self-adjoint second-order differential operator on an interval \((a, b)\), with prescribed boundary conditions at endpoints \( a \) and \( b \). As we will focus on the particular well-studied case of the operators \( L_d \) in Eq. (1.21), we skip mathematical details and eventual constraints known from the spectral theory of ordinary differential operators [50]. In particular, we postulate that the spectrum of the operator \( \mathcal{L} \) is discrete that is clearly the case in our setting.

The third strategy relies on computing the Green’s function \( G_q(r, r_0) \), i.e. the resolvent of the operator \( \mathcal{L} \) (acting on \( r \)) that obeys the equation

\[
(q^2 - \mathcal{L}) G_q(r, r_0) \omega(r_0) = \delta(r - r_0),
\]

where \( \omega(r_0) \) is a given positive weighting function (see below). On one hand, the standard construction of \( G_q(r, r_0) \) involves two linearly independent solutions \( v^a_q \) and \( v^b_q \) of the homogeneous equation \([q^2 - \mathcal{L}] v^a,b_q = 0\) such that \( v^a_q \) satisfies the boundary condition at \( r = a \) and \( v^b_q \) satisfies the boundary condition at \( r = b \). From these two solutions, one can construct the Green’s function as

\[
G_q(r, r_0) = \omega^{-1}(r_0) \times \begin{cases} 
A v^a_q(r) & (a < r < r_0), \\
B v^b_q(r) & (r_0 < r < b), 
\end{cases}
\]

where the coefficients \( A \) and \( B \) are determined by matching these parts at the point \( r = r_0 \) to ensure the continuity of \( G_q(r, r_0) \) and the unit jump of its derivative. One gets thus

\[
G_q(r, r_0) = \frac{\omega^{-1}(r_0)}{v^b_q(r_0) v^b_q(r_0) - v^a_q(r_0) v^a_q(r_0)} \times \begin{cases} 
v^b_q(r_0) v^a_q(r) & (a \leq r \leq r_0), \\
v^a_q(r_0) v^b_q(r) & (r_0 \leq r \leq b).
\end{cases}
\]

On the other hand, the function \( v^\lambda_q(r) \) with a non-negative \( \lambda \) is a natural candidate to be an eigenfunction of the operator \( \mathcal{L} \) (a similar construction is applicable to \( \psi^\lambda_q(r) \)). Indeed, this function obeys the eigenvalue equation, \( \mathcal{L} u + \lambda u = 0 \), with the imposed boundary condition at \( r = a \). The remaining boundary condition at \( r = b \) determines the (infinite) set of eigenvalues of this operator that we denote as \( \lambda_k \), with the index \( k = 1, 2, \ldots \). The corresponding eigenfunctions are then

\[
u_k(r) = i v^\lambda_{i\sqrt{\lambda_k}}(r),
\]

where the prefactor \( i \) was introduced for convenience. Denoting

\[
l_k^2 = \left( \int_a^b d r \omega(r) |u_k(r)|^2 \right)^{-1}
\]

the imposed boundary condition at \( \lambda = r \) where the prefactor \( v \) and \( bq \) candidate to be an eigenfunction of the operator \( \mathcal{L} \) (a similar construction is applicable to \( \psi^\lambda_q(r) \)). Indeed, this function obeys the eigenvalue equation, \( \mathcal{L} u + \lambda u = 0 \), with the imposed boundary condition at \( r = a \). The remaining boundary condition at \( r = b \) determines the (infinite) set of eigenvalues of this operator that we denote as \( \lambda_k \), with the index \( k = 1, 2, \ldots \). The corresponding eigenfunctions are then

\[
u_k(r) = i v^\lambda_{i\sqrt{\lambda_k}}(r),
\]

where the prefactor \( i \) was introduced for convenience. Denoting

\[
l_k^2 = \left( \int_a^b d r \omega(r) |u_k(r)|^2 \right)^{-1}
\]
In particular, the denominator in the right-hand side of Eq. (4.7) becomes

$$G_q(r, r_0) = \sum_{k=1}^{\infty} c_k^2 \frac{u_k(r) u_k^*(r_0)}{q^2 + \lambda_k}. \quad (4.6)$$

Equating relations (4.3) and (4.6), one gets an explicit summation formula over the eigenvalues $\lambda_k$:

$$\sum_{k=1}^{\infty} c_k^2 u_k(r) u_k^*(r_0) = \frac{\omega^{-1}(x_0)}{v_q^a(r_0)v_q^a(r) - v_q^b(r_0)v_q^b(r)} \times \begin{cases} v_q^b(r_0)v_q^a(r) & (a \leq r \leq r_0), \\ v_q^a(r_0)v_q^b(r) & (r_0 \leq r \leq b). \end{cases} \quad (4.7)$$

Multiplying both sides of this formula by an integrable function $f(r_0)$ (with the weighting function $\sqrt{\omega(r)}$) and integrating over $r$ and $r_0$, one can deduce many other summation formulas.

In the following, we focus on Robin boundary condition (1.20), which reads for the Green’s function as

$$\ell_a G_q(r, r_0) - G_q(r, r_0) \big|_{r=a} = 0, \quad \ell_b G_q(r, r_0) + G_q(r, r_0) \big|_{r=b} = 0. \quad (4.8)$$

If $I(r)$ and $K(r)$ denote two linearly independent solutions of the differential equation $Lu = u$, then the functions $v_q^{a,b}$ can be expressed as their linear combinations:

$$v_q^a(r) = w^{11}_q I(qr) - w^{12}_q K(qr), \quad (4.10)$$

$$v_q^b(r) = w^{21}_q I(qr) - w^{22}_q K(qr), \quad (4.11)$$

with coefficients

$$w^{11}_q = q\ell_a K'(qa) - K(qa), \quad w^{12}_q = q\ell_a I'(qa) - I(qa), \quad (4.12)$$

$$w^{21}_q = q\ell_b K'(qb) + K(qb), \quad w^{22}_q = q\ell_b I'(qb) + I(qb). \quad (4.13)$$

In particular, the denominator in the right-hand side of Eq. (4.7) becomes

$$v_q^b(r_0)[v_q^a(r_0)]' - v_q^a(r_0)[v_q^b(r_0)]' = -qV(q)W(qr_0), \quad (4.14)$$

where

$$V(q) = w^{11}_q w^{22}_q - w^{12}_q w^{21}_q \quad (4.15)$$

and

$$W(z) = K(z)I'(z) - I(z)K'(z) \quad (4.16)$$

is the Wronskian of two solutions.
D. S. Grebenkov

The Robin boundary condition for an eigenfunction \( -iv^a_{\sqrt{\lambda}}(r) \) at \( r = b \) yields an equation on the eigenvalues

\[
V(iq) = 0. \tag{4.17}
\]

Denoting the solutions of this equation as \( q_k \) (with \( k = 1, 2, \ldots \)), one gets the eigenvalues and eigenfunctions

\[
\lambda_k = q_k^2, \quad u_k(r) = w_{1q_k}^{11} I(iq_k r) - w_{1q_k}^{12} K(iq_k r). \tag{4.18}
\]

The general relation (4.7) can thus be written as

\[
\sum_{k=1}^{\infty} c_k^2 u_k(r) u^*_k(r_0) = -\frac{v^0_\lambda(r_0) v^0_\lambda(r)}{q V(q) W(qr_0) \omega(r_0)} \quad (a \leq r \leq r_0 \leq b) \tag{4.19}
\]

(the other case \( r \geq r_0 \) is obtained in a similar way). As the operator \( \mathcal{L} \) with Robin boundary conditions is self-adjoint, its eigenfunctions \( u_k(r) \) form a complete basis in the space of square-integrable functions on \((a, b)\) with the weighting function \( \omega(r_0) \). The completeness relation can be formally written as

\[
\omega(r_0) \sum_{k=1}^{\infty} c_k^2 u_k(r) u^*_k(r_0) = \delta(r - r_0) \quad (a \leq r \leq b, \ a \leq r_0 \leq b). \tag{4.20}
\]

4.2. One-dimensional case

Due to the translational invariance in one dimension, diffusion on the interval \((a, b)\) is fully equivalent to that on the shifted interval \((0, b-a)\). Without loss of generality, we set then \( a = 0 \) and consider diffusion on \((0, b)\), which is described by the second-order derivative, \( \mathcal{L}_1 = \partial^2_r \). Two linearly independent solutions of the equation \( u'' - u = 0 \) read

\[
I(r) = \sinh(r), \quad K(r) = \cosh(r), \tag{4.21}
\]

so that

\[
w_q^{21} = q \ell_b \sinh(qb) + \cosh(qb), \quad w_q^{22} = q \ell_b \cosh(qb) + \sinh(qb), \tag{4.23}
\]

and

\[
V(q) = -(q^2 \ell_0 \ell_b + 1) \sinh(qb) - q(\ell_0 + \ell_b) \cosh(qb), \tag{4.24}
\]

from which

\[
v_\lambda^0(r) = - \sinh(qr) - q \ell_0 \cosh(qr), \tag{4.25}
\]

\[
v_\lambda^0(r) = - \sinh(q(b-r)) - q \ell_b \cosh(q(b-r)). \tag{4.26}
\]

The eigenvalues are determined as \( \lambda_k = q_k^2 \), with \( q_k \) being the positive solutions of the equation

\[
V(iq) = i[q^2 \ell_0 \ell_b - 1] \sinh(qb) - q(\ell_0 + \ell_b) \cos(qb)] = 0, \tag{4.27}
\]

2130002-22
while the eigenfunctions from Eq. (4.14) have a form
\[ u_k(r) = \sin(q_k r) + q_k \ell_0 \cos(q_k r). \] (4.28)
Integrating \( u_k^2 \) with the weighting function \( \omega(r_0) = 1 \) and using trigonometric identities, one finds
\[ c_k^2 = \frac{2h_0^2(\alpha_k^2 + \alpha_k^2 h_0^2 + h_0^2 h_0^2)}{b} \{ \alpha_k^6 + \alpha_k^4(2h_0^2 + h_0^2 + h_0 + h_b) 
+ \alpha_k^2(h_0^2 h_0^2 + 2h_0^2 + h_0(h_b + h_0)^2) + (h_0 + h_b + h_0 h_b) h_0 h_0^3 \}^{-1}, \] (4.29)
where \( \alpha_k = b q_k, \ h_0 = b/\ell_0, \ h_b = b/\ell_b \) (4.30)
are dimensionless quantities. It is also convenient to rewrite Eq. (4.27) as an equation on \( \alpha_k \):
\[ \cot \alpha - \frac{\alpha^2 - h_0 h_b}{\alpha(h_0 + h_b)} = 0. \] (4.31)
As the function in the left-hand side is continuous and monotonously decreasing on an interval \((\pi(k - 1), \pi k)\) from \(+\infty\) to \(-\infty\) (that can be checked by computing its derivative), there is a single zero \( \alpha_k \) on each such interval, implying \( \pi(k - 1) \leq \alpha_k \leq \pi k \) for \( k = 1, 2, \ldots \).

Using Eq. (4.14) and \( W(z) = 1 \), the summation formula (4.19) becomes
\[ \sum_{k=1}^{\infty} c_k^2 \frac{u_k(r) u_k(r_0)}{q^2 + \lambda_k} = \frac{[\sinh(qr) + q \ell_0 \cosh(qr)] [\sinh(q(b - r_0)) + q f_b \cosh(q(b - r_0))]}{q ([q^2 \ell_0 \ell_b + 1] \sinh(qb) + q (\ell_0 + \ell_b) \cosh(qb))} \] (4.32)
for \( 0 \leq r \leq r_0 \leq b \). Note that the left-hand side is precisely the Laplace-transformed heat kernel:
\[ \tilde{P}(r, p | r_0) = \frac{1}{D} \sum_{k=1}^{\infty} c_k^2 \frac{u_k(r) u_k(r_0)}{p/D + \lambda_k}, \] (4.33)
so that Eq. (4.32) yields its analytical form, with \( q = \sqrt{p/D} \). From the identity (4.32), one can derive various summation formulas. For instance, setting \( r_0 = r \) and integrating over \( r \) from 0 to \( b \), one finds
\[ \sum_{k=1}^{\infty} \frac{1}{q^2 + \lambda_k} = \frac{q b [q^2 \ell_0 \ell_b + 1] \cosh(qb) + (q^2 (\ell_0 \ell_b + b (\ell_0 + \ell_b)) - 1) \sinh(qb)}{2 q^2 ([q^2 \ell_0 \ell_b + 1] \sinh(qb) + q (\ell_0 + \ell_b) \cosh(qb))}, \] (4.34)
which is proportional to the Laplace-transformed heat trace \( \tilde{Z}(p) \).

The particular cases of the general identity (4.32) corresponding to nine combinations of boundary conditions at two endpoints are summarized in Table 2.
Table 2. Summary of summation formulas for the nine combinations of boundary conditions at the endpoints of the unit interval \((b = 1)\). Here \(k = 1, 2, \ldots, 0 \leq x \leq x_0 \leq 1, 0 < h < \infty, z\) is a complex number, and \(Z = \sum_{k=1}^{\infty} \frac{1}{k + \alpha_k}\). For convenience, we rescale Eqs. 4.28 and 4.29 by \(h\) to get: \(u_k(x) = h \sin(\alpha_k x) + \alpha_k \cos(\alpha_k x)\) and \(v(x; z; h) = h \sinh(z x) + z \cosh(z x)\).

| Boundary Condition | Robin \((h_1 = h)\) | Neumann \((h_1 = 0)\) | Dirichlet \((h_1 = \infty)\) |
|-------------------|---------------------|---------------------|---------------------|
| \(h_0 = h\)      | \(\tan \alpha_k = \frac{2h\alpha_k}{\alpha_k^2 - h^2}\) \(u_k(x) u_k(x_0)\) \(\frac{1}{2\pi^2} \sum_{k=1}^{\infty} \frac{\cos(\alpha_k x) \cos(\alpha_k x_0) (\alpha_k^2 + h^2)}{\alpha_k} (1 - x_0; \alpha_k^2 + h^2) \cos(\alpha_k x_0) \cos(\alpha_k x)\) \(\alpha_k = \pi\) \(k - 1\) \(\alpha_k = \pi\) \(k - 1\) \(\alpha_k = \pi\) \(k - 1\) \(\alpha_k = \pi\) \(k - 2\) |
| \(h_0 = 0\)      | \(\tan \alpha_k = h\) \(\frac{1}{2\pi^2} \sum_{k=1}^{\infty} \frac{\alpha_k}{\alpha_k^2} (1 - x_0; \alpha_k^2 + h^2) \cos(\alpha_k x_0) \cos(\alpha_k x)\) \(\frac{1}{2\pi^2} \sum_{k=1}^{\infty} \frac{\alpha_k}{\alpha_k^2} (1 - x_0; \alpha_k^2 + h^2) \cos(\alpha_k x_0) \cos(\alpha_k x)\) \(\cos(\alpha_k x_0) \cos(\alpha_k x)\) \(\cos(\alpha_k x_0) \cos(\alpha_k x)\) \(\cos(\alpha_k x_0) \cos(\alpha_k x)\) |
| \(h_0 = \infty\) | \(\alpha_k = -\alpha_k/h\) \(\frac{1}{2\pi^2} \sum_{k=1}^{\infty} \frac{\cos(\alpha_k x) \sin(\alpha_k x_0) (\alpha_k^2 + h^2)}{\alpha_k} (1 - x_0; \alpha_k^2 + h^2) \sin(\alpha_k x_0) \sin(\alpha_k x)\) \(\frac{1}{2\pi^2} \sum_{k=1}^{\infty} \frac{\cos(\alpha_k x) \sin(\alpha_k x_0) (\alpha_k^2 + h^2)}{\alpha_k} (1 - x_0; \alpha_k^2 + h^2) \sin(\alpha_k x_0) \sin(\alpha_k x)\) \(\cos(\alpha_k x_0) \sin(\alpha_k x)\) \(\cos(\alpha_k x_0) \sin(\alpha_k x)\) \(\cos(\alpha_k x_0) \sin(\alpha_k x)\) |
instance, in the Neumann–Neumann case ($\ell_0 = \ell_b = \infty$), for which $\alpha_k = \pi(k - 1)$ (with $k = 1, 2, \ldots$), one has
\[
\sum_{k=1}^{\infty} \frac{\cos(\pi k x) \cos(\pi k x_0)}{x^2 + \pi^2 k^2} = \frac{\cosh(z(1 - x_0)) \cosh(z x)}{2z \sinh z} - \frac{1}{2z^2} \quad (0 \leq x \leq x_0 \leq 1),
\]
(4.35)
where we fixed $b = 1$. Setting $x = x_0 = 0$, one retrieves Eq. (2.131). In the particular cases of Dirichlet–Dirichlet and Neumann–Neumann conditions, many summation formulas can be deduced from standard Fourier series, e.g.,
\[
\sum_{k=1}^{\infty} \frac{\cos(\pi k x)}{\pi k} = -\frac{1}{2\pi} \ln(2 - 2 \cos(\pi x)) \quad (0 < x \leq 1).
\]
(4.36)

### 4.3. Two-dimensional case

In two dimensions, the problem $\mathcal{L}_2 u = 0$ with the radial operator $\mathcal{L}_2$ from Eq. (4.3) is reduced to the modified Bessel equation whose two linearly independent solutions are the modified Bessel functions $I_n(z)$ and $K_n(z)$. While most of the following results are applicable for $n \in \mathbb{R}$ (or even $n \in \mathbb{C}$), we restrict our discussion to the case of an integer $n$, which is most relevant for the Laplace operator in two-dimensional rotation-invariant domains.

#### 4.3.1. Circular annulus

In the following, the general results are applied for a fixed $n$ by setting
\[
I(r) = I_n(r), \quad K(r) = K_n(r).
\]
(4.37)
Using the relations
\[
I_n(-iz) = (-i)^n J_n(z), \quad K_n(-iz) = \frac{\pi i^{n+1}}{2} (J_n(z) + iY_n(z)),
\]
(4.38)
one gets
\[
\psi_{n,q}^i(r) = -\frac{\pi}{2} \left( (qY_n'(qb) + h_b J_n(qb)) J_n(qr) - (qJ_n'(qb) + h_b J_n(qb)) Y_n(qr) \right).
\]
(4.39)
For convenience, we change a numerical factor in our former expression for eigenfunctions to write
\[
u_{nk}(r) = (q_{nk}^a \ell_b Y_n'(q_{nk} b) + Y_n(q_{nk} b)) J_n(q_{nk} r)
\]
\[
- (q_{nk}^a \ell_b J_n'(q_{nk} b) + J_n(q_{nk} b)) Y_n(q_{nk} r),
\]
(4.40)
where $q_{nk}$ are the positive solutions of the equation
\[
(q_{nk} a Y_n'(qa) - Y_n(qa))(q_{nk} J_n'(qb) + J_n(qb))
\]
\[
- (q_{nk} a J_n'(qa) - J_n(qa))(q_{nk} b Y_n'(qb) + Y_n(qb)) = 0,
\]
(4.41)
enumerated by the index \( k = 1, 2, 3, \ldots \). The Laplacian eigenvalues are \( \lambda_k = q_k^2 \).

The standard computation yields the \( L_2 \)-normalization coefficients of the eigenfunction with the weighting function \( \omega(r_0) = r_0 \):
\[
\psi_{nk}^2 = 2q_k^2 \left\{ (b^2(u_{nk}'(b))^2) + (q_k^2 b^2 - a^2)(u_{nk}(b))^2 \right\} - \left\{ (a^2(u_{nk}'(a))^2) + (q_k^2 a^2 - b^2)(u_{nk}(a))^2 \right\}^{-1}.
\]
(4.42)

Using the Wronskian of the functions \( I_n(z) \) and \( K_n(z) \),
\[
W(z) = I'_n(z)K_n(z) - I_n(z)K'_n(z) = \frac{1}{z},
\]
(4.43)
one rewrites Eq. (4.19) for each \( n \) as
\[
\sum_{k=1}^{\infty} c_{nk}^2 \frac{u_{nk}(r)u_{nk}'(r_0)}{q^2 + \lambda_k} = - \frac{v_{n,q}^a(r_0) v_{n,q}^b(r)}{V_n(q)} \quad (a \leq r \leq r_0 \leq b),
\]
(4.44)
where
\[
v_{n,q}^a(r) = (q\ell_a K'_n(qa) - K_n(qa))I_n(qr) - (q\ell_a I'_n(qa) - I_n(qa))K_n(qr),
\]
(4.45)
\[
v_{n,q}^b(r) = (q\ell_b K'_n(qb) + K_n(qb))I_n(qr) - (q\ell_b I'_n(qb) + I_n(qb))K_n(qr),
\]
(4.46)
and
\[
V_n(q) = (q\ell_a K'_n(qa) - K_n(qa))(q\ell_b I'_n(qb) + I_n(qb))
\]
\[
- (q\ell_b K'_n(qb) + K_n(qb))(q\ell_a I'_n(qa) - I_n(qa)).
\]
(4.47)

Eq. (4.44) is the main summation formula for circular annuli.

Setting \( r_0 = r \) and integrating over \( r \) from \( a \) to \( b \) with the weighting function \( \omega(r_0) = r_0 \), one deduces
\[
\sum_{k=1}^{\infty} \frac{1}{q^2 + \lambda_k} = \frac{S_n(a) - S_n(b)}{2q^2V_n(q)},
\]
(4.48)
with
\[
S_n(r) = (q^2 r^2 + n^2)\nu_{n,q}^a(r)\nu_{n,q}^b(r) - r^2[\nu_{n,q}^a(r)][\nu_{n,q}^b(r)]',
\]
(4.49)
where we employed the modified Bessel equation for functions \( I_n(z) \) and \( K_n(z) \) to calculate the integral:
\[
\int_a^b dr \, r \, \nu_{n,q}^a(r) \, \nu_{n,q}^b(r) = \frac{S_n(b) - S_n(a)}{2q^2}.
\]
(4.50)

Using the explicit form of the \( L_2 \)-normalized Laplacian eigenfunctions in polar coordinates,
\[
U_{nk}(r, \phi) = \frac{1}{\sqrt{2\pi}} \, c_{nk} \, u_{nk}(r) \, e^{in\phi},
\]
(4.51)
A physicist’s guide to explicit summation formulas

one rewrites the spectral representations of the heat kernel and Laplace-transformed heat kernel in \( \Omega \) as

\[
P(x, t \mid x_0) = \frac{1}{2\pi} \sum_{n=-\infty}^{\infty} e^{in(\phi - \phi_0)} \sum_{k=1}^{\infty} c_{nk}^{2} u_{nk}(r) u_{nk}(r_0) e^{-D\lambda_{nk}}
\] (4.52)

and

\[
\tilde{P}(x, p \mid x_0) = \frac{1}{2\pi} \sum_{n=-\infty}^{\infty} e^{in(\phi - \phi_0)} \sum_{k=1}^{\infty} c_{nk}^{2} u_{nk}(r) u_{nk}(r_0) \frac{1}{p + D\lambda_{nk}}.
\] (4.53)

On the other hand, using the summation formula (4.44), one gets an alternative, more explicit representation for \( a \leq r \leq r_0 \leq b \):

\[
\tilde{P}(x, p \mid x_0) = -\frac{1}{2\pi D} \sum_{n=-\infty}^{\infty} e^{in(\phi - \phi_0)} \frac{v_{n,q}(r_0) v_{n,q}(r)}{V_n(q)},
\] (4.54)

with \( q = \sqrt{pD} \) (see Table \([4]\) for several examples\(^b\)).

4.3.2. Disk

For the disk of radius \( b \), one takes the limit \( a \to 0 \), at which \( w_{n,q}^{11} = q\ell_{n}^2 K'_{n}(qa) - K_{n}(qa) \) diverges that simplifies various expressions. Table \([3]\) summarizes most relevant summation formulas for both Dirichlet and Robin/Neumann boundary conditions. In particular, Eqs. (4.44) and (4.48) are reduced to Eqs. (D1) and (D2) from that table. At \( x_0 = 1 \), Eq. (D1) yields Eq. (D3). Setting \( s = 1 \), substituting \( z \) by \( \sqrt{s} \) and differentiating by \( s \) this identity \( m \) times, one recovers Eq. (3.10) after an explicit evaluation of the derivatives in the right-hand side. The identities (D4)–(D6) are obtained by replacing \( z \) by \( -iz \) in Eqs. (D1)–(D3), whereas the identities (D7)–(D12) are deduced from Eqs. (D1)–(D6) in the limit \( \ell_{b} \to 0 \) or \( h = b/\ell_{b} \to \infty \) (Dirichlet condition). Note that Eqs. (D9) and (D12) can alternatively be written as

\[
\frac{I_{n}(zx)}{I_{n}(z)} = x^n + 2x^2 \sum_{k=1}^{\infty} \frac{J_{n}(\alpha_{nk})}{(z^2 + \alpha_{nk}^2)\alpha_{nk}J'_{n}(\alpha_{nk})}.
\] (4.55)

and

\[
\frac{J_{n}(zx)}{J_{n}(z)} = x^n + 2x^2 \sum_{k=1}^{\infty} \frac{J_{n}(\alpha_{nk})}{(z^2 - \alpha_{nk}^2)\alpha_{nk}J'_{n}(\alpha_{nk})}.
\] (4.56)

Note also that Eq. (D8) reproduces Eq. (2.23) for the disk, whereas Eq. (D10) is a particular form of the Kneser–Sommerfeld expansion.\(^c\)

\(^b\)Some expressions from Table \([4]\) were provided in \([3]\). Note that the right-hand side of Eq. (A.7) in that reference should be multiplied by \(-1\).

\(^c\)As indicated in \([2]\), the Kneser–Sommerfeld expansion provided by Watson (see \([27], p. 499\)) has to be corrected. We checked numerically that Watson’s expression is indeed not valid.
Table 3. Summary of summation formulas for a disk and a ball of radius \( h \). Here \( 0 \leq x \leq x_0 \leq 1 \), and \( \alpha_{n,k} = b_{n,k} \) are the positive zeros of \( g_n(z) = zJ_n^0(z) + hJ_n(z) \) in two dimensions, and of \( g_n(z) = zJ_n^0(z) + hJ_n(z) \) in three dimensions, with \( h = b/\ell_0 \). Expressions for Neumann boundary condition are simply deduced by setting \( h = 0 \).

| \[ \sum_{k=1}^{\infty} \frac{1}{\alpha_n^2 + \alpha_{n,k}^2 h J_n(o_{n,k} x)} = \frac{J_n(z)}{2 J_n(x)} \] | \[ \sum_{k=1}^{\infty} \frac{1}{\alpha_n^2 + \alpha_{n,k}^2 h J_n(o_{n,k} x)} = \frac{J_n(z)}{2 J_n(x)} \] |
| Dirichlet \( \ell_0 = 8 \) |
Table 4. Explicit forms for the Laplace-transformed heat kernel $\tilde{P}(x, p | x_0)$ for several circular domains: the disk of radius $L$ with Dirichlet (D) or Neumann (N) boundary condition; the exterior of a disk of radius $R$ (D/N); and the annulus between two circles of radii $R < L$, with four combinations of Dirichlet/Neumann boundary conditions (DD, DN, ND, NN) at the inner/outer circles, respectively. Here $x = (r, \phi)$ and $x_0 = (r_0, \phi_0)$ in polar coordinates, and $q = \sqrt{r^2 + r_0^2}$. The Laplace-transformed heat kernel $\tilde{P}(x, p | x_0)$ for similar spherical domains is given by the last expression, in which $r = |x|$, $r_0 = |x_0|$, $P_n(z)$ are Legendre polynomials, and the functions $g_n^\pm(r)$ and $g_n^\pm(r_0)$ keep the same form as for circular domains, but the modified Bessel functions $I_n(z)$ and $K_n(z)$ should be replaced by the modified spherical Bessel functions $i_n(z)$ and $k_n(z)$, respectively.

| Circular domains | $\tilde{P}(x, p | x_0) = \frac{1}{2\pi D} \sum_{n=-\infty}^{\infty} e^{i(n-\phi_0)q} g_n^\pm(\min\{r_0, r\}) g_n^\pm(\max\{r_0, r\})$ |

D. S. Grebenkov

In three dimensions, a substitution $u(r) = \tilde{u}(r)/\sqrt{r}$ reduces the eigenvalue equation $\mathcal{L}_3 u = u$ with the radial operator $\mathcal{L}_3$ from Eq. (1.21) to the modified Bessel equation

$$r^2 \tilde{u}'' + r \tilde{u}' - [r^2 + (n + 1/2)^2] \tilde{u} = 0.$$  \hspace{1cm} (4.58)

As a consequence, one can formally extend most of the results of the previous subsection by substituting $u(r)$ by $\sqrt{r} u(r)$ and $n$ by $n + 1/2$.

4.4. Three-dimensional case

In three dimensions, a substitution $u(r) = \tilde{u}(r)/\sqrt{r}$ reduces the eigenvalue equation $\mathcal{L}_3 u = u$ with the radial operator $\mathcal{L}_3$ from Eq. (1.21) to the modified Bessel equation

$$r^2 \tilde{u}'' + r \tilde{u}' - [r^2 + (n + 1/2)^2] \tilde{u} = 0.$$  \hspace{1cm} (4.58)

As a consequence, one can formally extend most of the results of the previous subsection by substituting $u(r)$ by $\sqrt{r} u(r)$ and $n$ by $n + 1/2$.

4.4.1. Spherical shell

Two linearly independent solutions of the equation $\mathcal{L}_3 u = u$ are the modified spherical Bessel functions, $i_n(z)$ and $k_n(z)$, which are related to the modified Bessel functions $I_n(z)$ and $K_n(z)$ as

$$i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z), \quad k_n(z) = \sqrt{\frac{2}{\pi z}} K_{n+1/2}(z).$$  \hspace{1cm} (4.59)

For each fixed $n$, we set therefore

$$I(x) = i_n(x), \quad K(x) = k_n(x).$$  \hspace{1cm} (4.60)

Using the following relations

$$i_n(iz) = i^n j_n(z), \quad k_n(iz) = -(-i)^n j_n(z) = -i^{n+1} y_n(z),$$  \hspace{1cm} (4.61)

where

$$j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z), \quad y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z)$$  \hspace{1cm} (4.62)

are the spherical Bessel functions of the first and second kind, we get, after simplifications,

$$u_{nk}(r) = \left(q_{nk} \ell_a \ell'_a q_{nk} a - y_n(q_{nk} a)\right) j_n(q_{nk} r)$$
$$- \left(q_{nk} \ell_a j_n'(q_{nk} a) - j_n(q_{nk} a)\right) y_n(q_{nk} r).$$  \hspace{1cm} (4.63)
where \( q_{nk} \) are the positive solutions of the equation
\[
(q\ell_a k'_n(qa) - y_n(qa))(q\ell_b k'_n(qb) + j_n(qb))
- (q\ell_a j'_n(qa) - j_n(qa))(q\ell_b y'_n(qb) + y_n(qb)) = 0,
\]
(4.64)
enumerated by the index \( k = 1, 2, 3, \ldots \). The Laplacian eigenvalues are \( \lambda_{nk} = q_{nk}^2 \).

The standard computation yields the \( L_2 \) normalization of the eigenfunctions with the weighting function \( \omega(r_0) = r_0^2 \):
\[
c^n_{nk} = 2a^n_{nk} \left\{ b \left[ b^2 (u'_n(b))^2 + bu_n(b) u'_n(b) + (b^2 q_{nk}^2 - n(n + 1)) u_n^2(b) \right]
- a \left[ a^2 (u'_n(a))^2 + au_n(a) u'_n(a) + (a^2 q_{nk}^2 - n(n + 1)) u_n^2(a) \right] \right\}^{-1}.
\]
(4.65)

Using the Wronskian of the functions \( i_n(z) \) and \( k_n(z) \),
\[
W(z) = i'_n(z) k_n(z) - i_n(z) k'_n(z) = \frac{1}{z^2},
\]
(4.66)
one rewrites Eq. (4.19) for each \( n \) as
\[
\sum_{k=1}^{\infty} c^n_{nk} \frac{u_n(r) u'_n(r_0)}{q^2 + \lambda_{nk}} = -q \frac{v^n_{n,q}(r_0) v'_n(q) v_{n,q}(r)}{V_n(q)} \quad (a \leq r \leq r_0 \leq b),
\]
(4.67)
where
\[
v^n_{n,q}(r) = (q\ell_a k'_n(qa) - k_n(qa)) i_n(qr) - (q\ell_a i'_n(qa) - i_n(qa)) k_n(qr),
\]
(4.68)
\[
v^n_{b,q}(r) = (q\ell_b k'_n(qb) + k_n(qb)) i_n(qr) - (q\ell_b i'_n(qb) + i_n(qb)) k_n(qr),
\]
(4.69)
and
\[
V_n(q) = (q\ell_a k'_n(qa) - k_n(qa))(q\ell_b i'_n(qb) + i_n(qb))
- (q\ell_b k'_n(qb) + k_n(qb))(q\ell_a i'_n(qa) - i_n(qa)).
\]
(4.70)

Eq. (4.67) is the main summation formula for spherical shells.

Setting \( r_0 = r \) and integrating over \( r \) from \( a \) to \( b \) with the weighting function \( \omega(r_0) = r_0^2 \), one deduces
\[
\sum_{k=1}^{\infty} \frac{1}{q^2 + \lambda_{nk}} = \frac{S_n(a) - S_n(b)}{2q V_n(q)},
\]
(4.71)
with
\[
S_n(r) = r \left( (q^2 r^2 + n(n + 1)) v^n_{n,q}(r) v^n_{n,q}(r) - \frac{r}{2} \partial_r \left( v^n_{n,q}(r) v^n_{n,q}(r) \right) \right)
- r^2 v^n_{n,q}(r) v^n_{n,q}(r),
\]
(4.72)
where we employed the modified Bessel equation for functions \( i_n(z) \) and \( k_n(z) \) to calculate the integral:
\[
\int_a^b dr \ r^2 v^n_{n,q}(r) v^n_{n,q}(r) = \frac{S_n(b) - S_n(a)}{2q^2}.
\]
(4.73)
Using the explicit form of the $L_2$-normalized Laplacian eigenfunctions in spherical coordinates,

$$U_{nk}(r, \theta, \phi) = \sqrt{\frac{(2n+1)(n-l)!}{4\pi(n+l)!}} c_{nk} u_{nk}(r) P_n^l(\cos \theta) e^{il\phi},$$  \hspace{1cm} (4.74)

one rewrites the spectral representation of the heat kernel and Laplace-transformed heat kernel in $\Omega$ explicitly as:

$$P(x, t | x_0) = \frac{1}{4\pi} \sum_{n=0}^{\infty} (2n+1) P_n \left( \frac{(x \cdot x_0)}{\|x\| \|x_0\|} \right) \sum_{k=1}^{\infty} c_{nk}^2 u_{nk}(r) u_{nk}(r_0) e^{-Dt\lambda_{nk}}$$  \hspace{1cm} (4.75)

and

$$\tilde{P}(x, p | x_0) = \frac{1}{4\pi} \sum_{n=0}^{\infty} (2n+1) P_n \left( \frac{(x \cdot x_0)}{\|x\| \|x_0\|} \right) \sum_{k=1}^{\infty} c_{nk}^2 u_{nk}(r) u_{nk}(r_0) \frac{p + D\lambda_{nk}}{p},$$  \hspace{1cm} (4.76)

where the sum over $l$ from $-n$ to $n$ yielded, via the addition theorem for spherical harmonics, the Legendre polynomial $P_n \left( \frac{(x \cdot x_0)}{\|x\| \|x_0\|} \right)$ of the cosine of the angle between the vectors $x$ and $x_0$:

$$\sum_{l=-n}^{n} \frac{(n-l)!}{(n+l)!} P_n^l(\cos \theta) e^{il\phi} P_n^l(\cos \theta_0) e^{-il\phi_0} = P_n \left( \frac{(x \cdot x_0)}{\|x\| \|x_0\|} \right).$$  \hspace{1cm} (4.77)

On the other hand, using the summation formula \[4.67\], one gets an alternative, more explicit representation for $a \leq r \leq r_0 \leq b$:

$$\tilde{P}(x, p | x_0) = -\frac{q}{4\pi D} \sum_{n=0}^{\infty} (2n+1) P_n \left( \frac{(x \cdot x_0)}{\|x\| \|x_0\|} \right) \frac{v_n^b(r_0) v_n^a(r)}{V_n(q)},$$  \hspace{1cm} (4.78)

with $q = \sqrt{p/D}$ (see Table \[4\] for several examples).

4.4.2. Ball

For the ball of radius $b$, one takes the limit $a \to 0$, at which $w_{n,l}^a = g_{\ell_k} k_n^{\ell_k}(qa) - h_n(qa)$ diverges that simplifies various expressions. Table \[3\] summarizes the most relevant summation formulas for both Dirichlet and Robin/Neumann boundary conditions. In particular, Eqs. \[4.67\] and \[4.71\] are reduced to Eqs. (S1) and (S2) from that table. At $x_0 = 1$, Eq. (S1) yields Eq. (S3). Replacing $z$ by $-iz$ yields Eqs. (S4)-(S6), while the Dirichlet limit $\ell_k \to 0$ for $h = b/\ell_k \to \infty$ transforms Eqs. (S1)-(S6) to Eqs. (S7)-(S12). Note that Eq. (S2) reproduces Eq. (2.23) for the ball, whereas Eq. (S4) is a Knörrer-Sommerfeld expansion for spherical Bessel functions. We also note that the completeness relation \[4.20\] can be written explicitly in the case of the unit ball ($b = 1$) as

$$\delta(x - x_0) = 2\pi b^2 \sum_{k=1}^{\infty} \frac{j_n(\alpha_{nk} x) j_n(\alpha_{nk} x_0)}{j_n^2(\alpha_{nk}) - n(n+1)h^2 - h} \left( \begin{array}{c} 0 \leq x \leq 1 \\ 0 \leq x_0 \leq 1 \end{array} \right).$$  \hspace{1cm} (4.79)
5. Discussion and Conclusion

Simple domains remain toy models and emblematic examples in most applications. While such “spherical cows” cannot capture the geometric complexity of most biological, physical and engineering systems, they bring conceptual understanding of the underlying processes. Moreover, simple domains often play a role of building blocks for modeling more sophisticated environments or simulating diffusion and other processes [14–17]. For instance, the implementation of a fast random walk algorithm [53], in which the variable size of each displacement of a particle is adapted to the local environment, relies on the knowledge of diffusion inside balls (see [54] for a short review). This efficient algorithm was broadly used to model diffusion-limited growth phenomena [55–57], diffusion-reaction in porous media [58, 59], harmonic measure and other first-passage statistics [60, 61], diffusion-weighted signal in NMR [41, 62, 63].

The computation of the Laplace-transformed heat kernel in Sec. 4 is not limited to the considered basic domains and can be extended to multi-layered structures such as a sequence of parallel sheets, multiple co-axial cylinders of increasing radii, and multiple concentric spherical shells. For these structures, the transport properties are supposed to be constant in each layer, while transmission boundary conditions describe the exchange between neighboring layers. The radial eigenfunctions of the diffusion operator are still expressed in terms of basic solutions $I(z)$ and $K(z)$ in each layer, with the coefficients depending on the layer (see [64, 65] for details). As a consequence, one can generalize the results from Sec. 4 to investigate spectral sums in these domains that are often appear in modeling heat transfer in composite materials, drug release from multilayered capsules and drug-eluting stents, radioactive contamination of soils and waste disposal, etc. [66–73]. One can also consider diffusion in wedges, angular and spherical sectors [3, 30], as well as in the presence of confining potentials [74].

In summary, we presented an overview of several mathematical tools for computing explicitly the spectral sums involving zeros of linear combinations of Bessel functions. While each tool is fairly classical and most of the derived summation formulas are known, these results are dispersed in the literature. As a consequence, as it is often quite difficult to find out the needed tool or specific expression, most authors re-derive these formulas from scratch. The recent book by Thambynayagam [30] partly resolved this difficulty, providing on more than 2000 pages an exhaustive list of solutions of the diffusion equation in all kinds of one- and two-dimensional configurations. In spite of its advantages, the book does not focus on spectral sums, not present the methodological part, not discuss three-dimensional configurations. In this light, the present overview provides both a concise guide over rather generic spectral sums and a practical recipe for evaluating the particular ones. These techniques are particularly valuable for getting explicit solutions in some basic diffusion models and for investigating the asymptotic behavior of the associated heat kernels.
