ON A CERTAIN ADDITIVE DIVISOR PROBLEM

BERKE TOPACOGULLARI

Abstract. We prove an asymptotic formula for a variant of the binary additive divisor problem with linear factors in the arguments, which has a power saving error term and which is uniform in all involved parameters.

1. Introduction

Additive divisor problems have a rich history in analytic number theory. A classical example is given by the problem of finding asymptotic estimates for

\[ \sum_{n \leq x} d(n) d(n + h), \quad h \geq 1, \]  

also known as the binary additive divisor problem. There has been a lot of effort in studying this problem (see [24] for a historical survey), one reason being its intimate link to the fourth power moment of the Riemann zeta function.

In other applications to \( L \)-functions (see [3] and [10]), variations of this problem have come up, usually stated in the form

\[ D(x_1, x_2) := \sum_{r_1 n_2 - r_2 n_1 = h} w_1 \left( \frac{n_1}{x_1} \right) w_2 \left( \frac{n_2}{x_2} \right) d(n_1) d(n_2). \]  

Here \( r_1 \) and \( r_2 \) are positive coprime integers, \( h \) is non-zero, and \( w_1 \) and \( w_2 \) are smooth weight functions, which we assume to be compactly supported in \([1/2, 1]\) (the assumption that \( r_1 \) and \( r_2 \) be coprime is not restrictive – otherwise \( h \) has to be divisible by their greatest common divisor, and we can divide both sides of the equation by that number).

Although the classical case \( r_1 = r_2 = 1 \) has probably received most of the attention, there have been some nice results for general \( r_1, r_2 \) as well. Besides the implicit treatment in [3], there is the work of Duke, Friedlander and Iwaniec [11], who showed that

\[ D(x_1, x_2) = (\text{main term}) + O \left( \left( r_2 x_1 + r_1 x_2 \right)^{4 \over 5} (r_1 r_2 x_1 x_2)^{1+\varepsilon} \right). \]  

As they didn’t make use of spectral theory, the size of the error term is inferior compared to what can be achieved for [11]. Nevertheless, the range of uniformity in \( r_1, r_2 \) and \( h \) for which this asymptotic formula is non-trivial is quite impressive. At this point we also want to mention the work of Aryan [1], who improved the result in the case \( r_2 = 1 \).

With applications in mind that will be considered elsewhere, we have come across the following sum, which turned out to be an interesting problem in its own right:

\[ D(x_1, x_2) = \sum_n w_1 \left( \frac{r_1 n + f_1}{x_1} \right) w_2 \left( \frac{r_2 n + f_2}{x_2} \right) d(r_1 n + f_1) d(r_2 n + f_2). \]

Key words and phrases. divisor function, additive divisor problem, shifted convolution sum, Kuznetsov formula.

This work was supported by the Volkswagen Foundation.
Note that for \((r_1, r_2) = 1\) and the choice \(h = r_1f_2 - r_2f_1\), this is exactly the same sum as \((1.2)\). For \(r_1\) and \(r_2\) not coprime, however, we are confronted with a different problem and the following result seems to be new.

**Theorem 1.1.** Set

\[
  r_0 := \min\{(r_1, r_2), (r_2, r_1)\} \quad \text{and} \quad h := r_1f_2 - r_2f_1. 
\]

Then we have for \(h \neq 0\) and \(f_1 \ll x^{1-\varepsilon}, f_2 \ll x_2^{1-\varepsilon},\)

\[
  D(x_1, x_2) = M(x_1, x_2) + \mathcal{O}(r_0(r_2x_1)^{\frac{1}{2}+\theta+\varepsilon}),
\]

where the main term is given by

\[
  M(x_1, x_2) := \int w_1 \left( \frac{r_1\xi + f_1}{x_1} \right) w_2 \left( \frac{r_2\xi + f_1}{x_2} \right) P(\log(r_1\xi + f_1), \log(r_2\xi + f_2)) d\xi,
\]

with \(P(\xi, \xi)\) a quadratic polynomial depending on \(r_1, r_2, f_1\) and \(f_2\). The implicit constants depend only on \(w_1, w_2\) and on \(\varepsilon\).

By \(\theta\) we denote the bound in the Ramanujan-Petersson conjecture (see section 2.3 for a precise definition). The polynomial in the theorem above can be stated fairly explicitly, see (3.19). We haven’t aimed for the largest possible range of uniformity in \(f_1\) and \(f_2\). In fact, with some work it should be possible to extend our result to include \(f_1, f_2\) in a larger range than required above. It also seems likely that the dependance on \(r_0\) is not optimal, but here it is not immediately clear how an improvement might be achieved. Compared to [133] our result has a better error term, although their estimate is valid for much larger \(h\) than ours. In the case \(r_2 = 1\), our result is the same as [1] Theorem 0.3).

We also state the following analogous result for the sum with sharp cut-off.

**Theorem 1.2.** Let \(r_0\) and \(h \neq 0\) be defined as above. Assume that

\[
  f_1 \ll (r_1 x)^{1-\varepsilon}, \quad f_2 \ll (r_2 x)^{1-\varepsilon} \quad \text{and} \quad (r_0 r_1 r_2, h)h \ll r_0 \frac{1}{x} x^{\frac{1}{2}+\varepsilon}.
\]

Then

\[
  \sum_{0 < n \leq x} d(r_1n + f_1)d(r_2n + f_2) = xP(\log x) + \mathcal{O}\left((r_0 r_1 r_2, h)^{\theta} r_0 \frac{1}{x} x^{\frac{1}{2}+\varepsilon}\right),
\]

where \(P(\xi)\) is a quadratic polynomial depending on \(r_1, r_2, f_1\) and \(f_2\), and where the implicit constants only depend on \(\varepsilon\).

Correlations of a much more general type have been investigated by Matthiesen [24], but the methods used there don’t apply to our case and don’t give power savings in the error term. Similar problems, where the divisor functions are replaced by Fourier coefficients of automorphic forms, have been studied as well (see e.g. [2]). In particular, for Fourier coefficients of holomorphic cusp forms, Pitt [26] Theorem 1.4] was able to prove an analogue of our Theorem 1.1 for \(r_1, r_2\) squarefree and \(f_1 = f_2 = -1\). Unfortunately, his method relies on Jutila’s variant of the circle method and is not applicable to our case.

The proof of Theorems 1.1 and 1.2 follows standard lines: We split one of the divisor functions and use the Voronoi summation formula to deal with the divisor sum in arithmetic progressions. The main difficulty lies in the handling of the sum of Kloosterman sums entering the stage at this point. In a simplified form, we are faced with a sum roughly of the shape

\[
  \sum_{(c, r_2) = 1} \frac{S(1 - r_1r_2^2; 1; r_1c)}{r_1c} F(r_1c),
\]
where $F$ is some weight function, and where $\overline{r_2}$ is understood to be mod $c$. We could bound the Kloosterman sums individually using Weil’s bound, and the resulting error terms in our theorems would be of a size comparable to (1.3). Our aim however is to use spectral methods to get results beyond that.

If $r_1$ and $r_2$ are coprime, we can use the Kuznetsov formula with an appropriate choice of cusps to do that. Otherwise, it is not directly clear how the Kuznetsov formula might be put into use here. In this article we want to show that nevertheless this is possible. We solve the problem by splitting the variable $r_1 = tv$ into a factor $t$, which is coprime to $r_2$, and a factor $v$, which contains only the same prime factors as $r_2$. By twisted multiplicativity of Kloosterman sums we have

$$
\frac{S(1 - r_1 \overline{r_2}, 1; r_1c)}{r_1c} = \frac{S(tc, \overline{tc}; v)}{v} \frac{S(r_2 - r_1, v^2 r_2; tc)}{tc},
$$

where now all the inverses are understood to be modulo the respective modulus of the Kloosterman sum. Following an idea of Blomer and Miličević [5], we separate the variable $c$ occurring in the first factor by exploiting the orthogonality of Dirichlet characters, namely as follows

$$
\frac{S(tc, \overline{tc}; v)}{v} = \frac{1}{\varphi(v)} \sum_{\chi \mod v} \chi(tc) \hat{S}_c(\chi), \quad \text{with} \quad \hat{S}_c(\chi) := \sum_{y(v)} \chi(y) \frac{S(y, \overline{y}; v)}{v},
$$

where the left sum runs over all Dirichlet characters mod $v$. This way we are led to a sum of Kloosterman sums twisted by a Dirichlet character, which we can treat by spectral methods.

2. Preliminaries

Note that $\varepsilon$ always stands for some positive real number, which can be chosen arbitrarily small. However, it need not be the same on every occurrence, even if it appears in the same equation. To avoid confusion we also want to recall that as usual $e(z) := e^{2\pi iz}$, and that

$$
S(m, n; c) := \sum_{\substack{a(c) \mod c \equiv n}} e\left(\frac{ma + \overline{ma}}{c}\right) \quad \text{and} \quad c_q(n) := \sum_{\substack{a(q) \mod (a, q) = 1}} e\left(\frac{an}{q}\right),
$$

which are the usual notations for Kloosterman sums and Ramanujan sums.

2.1. The Voronoi summation formula and Bessel functions. Using the well-known Voronoi formula for the divisor function (see [15, Chapter 4.5] or [16, Theorem 1.6]) and the identity

$$
\sum_{\substack{n=1 \atop n \equiv b \mod c}}^{\infty} d(n)f(n) = \frac{1}{c} \sum_{d|c} \sum_{\ell(d) \atop \ell(d) = 1} e\left(\frac{-bf}{d}\right) \sum_{n=1}^{\infty} d(n)f(n)e\left(\frac{nf}{d}\right),
$$

it is not hard to show the following summation formula for the divisor function in arithmetic progressions:
Theorem 2.1. Let $b$ and $c \geq 1$ be integers. Let $f : (0, \infty) \to \mathbb{R}$ be smooth and compactly supported. Then

$$
\sum_{n \equiv b \pmod{c}} d(n) f(n) = \frac{1}{c} \int \lambda_{b,c}(\xi) f(\xi) \, d\xi
$$

$$
- \frac{2\pi}{c} \sum_{d|c} \sum_{n=1}^{\infty} d(n) \frac{S(b,n; d)}{d} \int Y_0 \left( \frac{4\pi}{d} \sqrt{n\xi} \right) f(\xi) \, d\xi
$$

$$
+ \frac{4}{c} \sum_{d|c} \sum_{n=1}^{\infty} d(n) \frac{S(b,-n; d)}{d} \int K_0 \left( \frac{4\pi}{d} \sqrt{n\xi} \right) f(\xi) \, d\xi,
$$

with

$$
\lambda_{b,c}(\xi) := \sum_{d|c} \frac{c_d(b)}{d} (\log \xi + 2\gamma - 2 \log d).
$$

Concerning the Bessel functions appearing in the above Theorem, we want to sum up some well-known facts. We know that

$$
K_0(\xi) \ll |\log \xi| \quad \text{for} \quad \xi \ll 1,
$$

$$
K_0(\xi) \ll \frac{1}{e^{\xi \sqrt{\xi}}} \quad \text{for} \quad \xi \gg 1,
$$

(2.1)

and that for $\mu \geq 1$,

$$
K_0^{(\mu)}(\xi) \ll \frac{1}{\xi^{\mu}} \quad \text{for} \quad \xi \ll 1, \quad \text{and} \quad K_0^{(\mu)}(\xi) \ll \frac{1}{e^{\xi \sqrt{\xi}}} \quad \text{for} \quad \xi \gg 1.
$$

Regarding the $Y$-Bessel function, we have for $\nu \geq 1$ and $\xi \ll 1$,

$$
Y_0(\xi) \ll |\log \xi|, \quad Y_\nu(\xi) \ll \frac{1}{\xi^{\nu}}, \quad \text{and} \quad Y_0^{(\mu)}(\xi) \ll \frac{1}{\xi^{\nu+\mu}} \quad \text{for} \quad \mu \geq 1.
$$

For $\nu \geq 0$ and $\xi \gg 1$, it is known that

$$
Y_\nu^{(\mu)}(\xi) \ll \frac{1}{\sqrt{\xi}} \quad \text{for} \quad \mu \geq 0.
$$

From the recurrence relation

$$
(\xi^\nu Y_\nu(\xi))' = \xi^\nu Y_{\nu-1}(\xi),
$$

we get the identity

$$
\int Y_0 \left( \frac{4\pi}{c} \sqrt{h\xi} \right) f(\xi) \, d\xi = \left( \frac{-2c}{4\pi h} \right)^{\nu} \int \xi^\nu Y_\nu \left( \frac{4\pi}{c} \sqrt{h\xi} \right) \frac{\partial^\nu f}{\partial \xi^\nu}(\xi) \, d\xi,
$$

(2.2)

which is useful when estimating the sizes of the Bessel transforms occurring in the Voronoi summation formula.

The $Y_\nu$-Bessel functions oscillate for large values, and to make use of this behaviour we state the following lemma.

Lemma 2.2. For any $\nu \geq 0$ there is a smooth function $v_\nu : (0, \infty) \to \mathbb{C}$ such that

$$
Y_\nu(\xi) = 2 \text{Re} \left( e^{i \nu \left( \frac{\xi}{2\pi} \right)} v_\nu \left( \frac{\xi}{2\pi} \right) \right),
$$

and such that for any $\mu \geq 0$,

$$
v_\nu^{(\mu)} \ll \frac{1}{\xi^{\mu+\frac{1}{2}}} \quad \text{for} \quad \xi \gg 1.
$$

Proof. This can be shown by using the integral representation (see [13, 3.871])

$$
Y_0(\xi) = -\frac{1}{\pi} \int_0^\infty \cos \left( \frac{x}{2\pi} + \frac{\pi \xi^2}{2x} \right) \frac{dx}{x},
$$
and applying the same variable substitution as in [7, Lemma 4]. See [25, Lemma 2.3] for more details.

2.2. The Hecke congruence subgroup and Kloosterman sums. Here and in the following sections we will go through some results from the theory of automorphic forms. A general description of the spectral theory of automorphic forms can be found for instance in [13] or [15, Chapters 14–16], while [12] gives a very nice introduction to Maaß forms of higher weight with arbitrary nebentypus.

Besides the Kuznetsov trace formula, our main tools are the large sieve inequalities, which were proven by Deshouillers and Iwaniec [8] with respect to Hecke congruence subgroups. Their results can be extended to our specific setting, the details of which have luckily been worked out by Drappeau [9]. Finally, we also want to cite [3] as a reference, where we borrow large parts of the notation.

Let \( q \) be some positive integer, let \( \kappa \in \{0, 1\} \), and let \( \chi \) be a character mod \( q_0 \), with \( q_0 | q \), such that

\[
\chi(-1) = (-1)^\kappa.
\]

Let \( \Gamma := \Gamma_0(q) \) be the Hecke congruence subgroup of level \( q \). The character \( \chi \) naturally extends to \( \Gamma \) by setting

\[
\chi(\gamma) := \chi(d) \quad \text{for} \quad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma.
\]

Every cusp \( a \) of \( \Gamma \) is equivalent to some \( u/w \) with \((u, w) = 1\) and \( w | q \). It is called singular if \( \chi(\gamma) = 1 \) for all \( \gamma \in \Gamma_a \), where \( \Gamma_a \) is the stabilizer of \( a \).

For any cusp \( a \) of \( \Gamma \) we can choose \( \sigma_a \in \text{SL}_2(\mathbb{R}) \) such that \( \sigma_a \infty = a \) and \( \sigma_a^{-1} \Gamma_a \sigma_a = \Gamma_\infty \).

Given two singular cusps \( a, b \), we define for \( n, m \in \mathbb{Z} \) the Kloosterman sum

\[
S_{ab}(m, n; \gamma) := \sum_{\delta \mod \gamma \mathbb{Z}} \chi(\sigma_a \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \sigma_b^{-1}) e\left(\frac{ma + n\delta}{\gamma}\right),
\]

where the sum runs over all \( \delta \mod \gamma \mathbb{Z} \), for which there exist some \( \alpha, \beta \) such that \( \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in \sigma_a^{-1} \Gamma \sigma_b \).

Note that this definition depends on the chosen scaling matrices \( \sigma_a \) and \( \sigma_b \).

As an example, for \( a = b = \infty \) and the choice \( \sigma_\infty = 1 \), the sum is non-empty exactly when \( q | c \) and in this case it reduces to the usual twisted Kloosterman sum

\[
S_{\infty \infty}(m, n; c) = S_{\chi}(m, n; c) := \sum_{\frac{a}{(c)}} \chi(a)e\left(\frac{ma + n\overline{a}}{c}\right).
\]

It is well-known that for any prime \( p \) this sum can be bound by

\[
S_{\chi}(m, n; p) \leq 2(m, n, p)\frac{1}{2}p^{\frac{1}{2}}.
\]

However, for general modulus we have to account for the conductor of \( \chi \) as well, and in this case the following bound holds (see [13, Theorem 9.2])

\[
S_{\chi}(m, n; c) \ll (m, n, c)^{\frac{1}{2}} q_0^{\frac{1}{2}} c^{\frac{1}{2} + \varepsilon}.
\]

Another important example is given for \( q \) having the form \( q = rs \) with \( (r, s) = 1 \) and \( q_0 | r \). Consider the two singular cusps \( \infty \) and \( \frac{1}{s} \), together with the choice

\[
\sigma_\frac{1}{s} = \left( \frac{\sqrt{r}}{s}, \sqrt{r}^{-1} \right).
\]
Now the sum $S_{\infty}(m, n; \gamma)$ is non-empty exactly when $\gamma$ may be written as

$$\gamma = \sqrt{sc}, \quad \text{with} \quad c \in \mathbb{Z} \setminus \{0\}, \quad (c, r) = 1,$$

and in this case we have

$$S_{\infty}(m, n; \gamma) = e\left(\frac{\pi}{n}\right)f(m, n; \gamma).$$

2.3. Automorphic forms and their Fourier expansions. By $S_k(q, \chi)$ we denote the finite-dimensional Hilbert space of holomorphic cusp forms of weight $k \equiv \kappa \mod 2$ with respect to $\Gamma_0(q)$ and with nebentypus $\chi$. Let $\theta_k(q, \chi)$ be its dimension. For each $k$, we choose an orthonormal Hecke eigenbasis $f_{j,k}$, $1 \leq j \leq \theta_k(q, \chi)$. Then the Fourier expansion of $f_{j,k}$ around a singular cusp $a$ (with associated scaling matrix $\sigma_a$) is given by

$$i(\sigma_a, z)^{-k}f_{j,k}(\sigma_az) = \sum_{n=1}^{\infty} \psi_{j,k}(n, a)(4\pi n)^{\frac{j}{4}}e(nx),$$

where we have set

$$i(\gamma, z) := cz + d \quad \text{for} \quad \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

Next, let $L^2(q, \chi)$ be the space of Maass forms of weight $\kappa$ with respect to $\Gamma_0(q)$ and with nebentypus $\chi$, and let $L^2_0(q, \chi) \subset L^2(q, \chi)$ be its subspace of Maass cusp forms. Let $u_j$, $j \geq 1$, run over an orthonormal Hecke eigenbasis of $L^2(q, \chi)$, with the corresponding real eigenvalues $\lambda_1 \leq \lambda_2 \leq \ldots$. We can assume each $u_j$ to be either even or odd. We set $t_j := \lambda_j - \frac{1}{4}$, where we choose the sign of $t_j$ so that $it_j \geq 0$ if $\lambda_j < \frac{1}{4}$, and $t_j \geq 0$ if $\lambda_j \geq \frac{1}{4}$. Then the Fourier expansions of these functions around a singular cusp $a$ is given by

$$j(\sigma_a, z)^{-k}u_j(\sigma_az) = \sum_{n \neq 0} \rho_j(n, a)W_{\frac{\pi}{|n|}, it_j}(4\pi|n|y)e(nx),$$

where

$$j(\gamma, z) := \frac{cz + d}{|cz + d|} \quad \text{for} \quad \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$
Note that by the choice of our basis, we have that
\[ |\rho_j(-n, \infty)| = |t|^\kappa |\rho_j(n, \infty)| \quad \text{for} \quad n \geq 1. \]
Furthermore, since all Eisenstein series are even, the same is true for their Fourier coefficients, namely
\[ |\varphi_{\epsilon, t}(-n, \infty)| = |t|^\kappa |\varphi_{\epsilon, t}(n, \infty)| \quad \text{for} \quad n \geq 1. \]

2.4. The Kuznetsov trace formula. With the whole notation set up, we can now formulate the famous Kuznetsov trace formula, which in our case reads as follows.

**Theorem 2.3.** Let \( f : (0, \infty) \rightarrow \mathbb{C} \) be smooth with compact support, let \( a, b \) be singular cusps, and let \( m, n \) be positive integers. Then
\[
\sum_{\gamma} S_{ab}(m, n; \gamma) f \left( 4\pi \frac{\sqrt{mn}}{\gamma} \right) = \sum_{j=1}^{\infty} \psi_j(m, a) \rho_j(n, b) \frac{\sqrt{mn}}{\cosh(\pi t_j)} f(t_j),
\]
\[
+ \sum_{\epsilon \in \text{sing.}} \frac{1}{4\pi} \int_{-\infty}^{\infty} \varphi_{\epsilon, t}(m, a) \varphi_{\epsilon, t}(n, b) \frac{\sqrt{mn}}{\cosh(\pi t)} \dot{f}(t) \, dt,
\]
\[
+ \sum_{k=2}^{\infty} (k-1)! \dot{\psi}_{j,k}(m, a) \dot{\psi}_{j,k}(n, b) \sqrt{mn} \ddot{f}(k),
\]
and
\[
\sum_{\gamma} S_{ab}(m, -n; \gamma) f \left( 4\pi \frac{\sqrt{mn}}{\gamma} \right) = \sum_{j=1}^{\infty} \psi_j(m, a) \rho_j(-n, b) \frac{\sqrt{mn}}{\cosh(\pi t_j)} f(t_j),
\]
\[
+ \sum_{\epsilon \in \text{sing.}} \frac{1}{4\pi} \int_{-\infty}^{\infty} \varphi_{\epsilon, t}(m, a) \varphi_{\epsilon, t}(-n, b) \frac{\sqrt{mn}}{\cosh(\pi t)} \dot{f}(t) \, dt,
\]
where \( \gamma \) runs over all positive real numbers for which \( S_{ab}(m, n; \gamma) \) is non-empty, and where the Bessel transforms are defined by
\[
\dot{f}(t) = \frac{2\pi t^\kappa}{\sinh(\pi t)} \int_{0}^{\infty} (J_{2\kappa}(\xi) - (-1)^\kappa J_{-2\kappa}(\xi)) f(\xi) \, d\xi,
\]
\[
\ddot{f}(k) = 8i^{\kappa} \cosh(\pi t) \int_{0}^{\infty} K_{2\kappa}(\xi) f(\xi) \, d\xi,
\]
\[
\dddot{f}(k) = 4i^{\kappa} \int_{0}^{\infty} J_{k-1}(\xi) f(\xi) \, d\xi.
\]

**Proof.** The proof of these formulas can be done along standard lines, as described for instance in [13, chapter 16.4] (see also [27]). The extension to our setting and to general cusps poses no real problems.

We just want to point out [12, Proposition 5.2], which can be used as a starting point for the proof. Its analogue for the case of mixed signs follows by a slight modification of the argument described there, and is given by
\[
\sum_{j=1}^{\infty} \frac{\psi_j(m, a) \rho_j(-n, b) \sqrt{mn}}{\cosh(\pi (r - t_j)) \cosh(\pi (r + t_j))} f \left( 4\pi \frac{\sqrt{mn}}{\gamma} \right) \gamma^2 K_{2\kappa} \left( \frac{4\pi \sqrt{mn}}{\gamma} \right),
\]
being true for positive integers \( m, n \) and \( r \in \mathbb{R} \).

In case \( a = b = \infty \), the sum of Kloosterman sums in the theorem above is just
\[
\sum_{\gamma} S_{\infty}(m, \pm n; \gamma) f \left( \frac{4\pi \sqrt{mn}}{\gamma} \right) = \sum_{c \equiv 0 (q)} S_{\chi}(m, \pm n; c) f \left( \frac{4\pi \sqrt{mn}}{c} \right),
\]
while in the case \( q = rs \) with \( (r, s) = 1 \) and \( q_0 | r \) mentioned above, we have
\[
\sum_{\gamma} S_{\infty}(m, \pm n; \gamma) f \left( \frac{4\pi \sqrt{mn}}{\gamma} \right) = e \left( \pm \frac{\pi s r}{r} \right) \sum_{c \equiv 0 (q)} S_{\chi}(m, \pm n; c) f \left( \frac{4\pi \sqrt{mn}}{\sqrt{rs c}} \right). \tag{2.3}
\]

To get some first estimates for the Bessel transforms appearing above we refer to \([4, Lemma 2.1]\), where the case \( \kappa = 0 \) is covered. The proofs carry over to the case \( \kappa = 1 \) with minimal changes.

**Lemma 2.4.** Let \( f : (0, \infty) \to \mathbb{C} \) be a smooth and compactly supported function such that
\[
\text{supp } f \lesssim X \quad \text{and} \quad f^{(\nu)}(\xi) \ll \frac{1}{Y^\nu} \quad \text{for } \nu = 0, 1, 2,
\]
for positive \( X \) and \( Y \) with \( X \gg Y \). Then
\[
\begin{align*}
\hat{f}(it), \tilde{f}(it) &\ll \frac{1 + Y^{-2t}}{1 + Y} \quad \text{for } 0 \leq t < \frac{1}{4}, \\
\hat{f}(t), \tilde{f}(t) &\ll \frac{1 + |\log Y|}{1 + Y} \quad \text{for } t \geq 0, \\
\hat{f}(t), \tilde{f}(t) &\ll \left( \frac{X}{Y} \right)^2 \left( \frac{1}{t^2} + \frac{X}{t^3} \right) \quad \text{for } t \gg \max(X, 1).
\end{align*}
\]

For oscillating functions, we can do better. Assume \( w : (0, \infty) \to \mathbb{C} \) to be a smooth and compactly supported function such that
\[
\text{supp } w \approx X \quad \text{and} \quad w^{(\nu)}(\xi) \ll \frac{1}{X^\nu} \quad \text{for } \nu \geq 0,
\]
and for \( \alpha > 0 \) define
\[
f(\xi) := e \left( \frac{\alpha \nu}{2\pi} \right) w(\xi).
\]
Then we have the following bounds.

**Lemma 2.5.** Assume that
\[
X \ll 1 \quad \text{and} \quad \alpha X \gg 1.
\]
Then for \( \nu, \mu \geq 0,
\[
\begin{align*}
\hat{f}(it), \tilde{f}(it) &\ll X^{-2t+\epsilon} \left( X^\mu + \frac{1}{(\alpha X)^\nu} \right) \quad \text{for } 0 < t \leq \frac{1}{4}, \tag{2.4} \\
\hat{f}(t), \tilde{f}(t) &\ll \frac{\alpha \nu}{\alpha X} \left( \frac{\alpha X}{t} \right)^\nu \quad \text{for } t > 0. \tag{2.5}
\end{align*}
\]

**Proof.** The bound (2.3) can be shown by making use of the Taylor series of the respective Bessel functions. The proof of (2.4) is a variation of the proof of [17, Lemma 3]. See [28, Lemma 2.6] for details. \qed
2.5. Large sieve inequalities and estimates for Fourier coefficients. Another important tool are the large sieve inequalities for Fourier coefficients of cusp forms and Eisenstein series. For a sequence \( a_n \) of complex numbers define

\[
\|a_n\|_N := \sqrt{\sum_{N < n \leq 2N} |a_n|^2},
\]

and furthermore set

\[
\begin{align*}
\Sigma^{(1)}_{j,\pm}(N) &:= \frac{(1 + |t_j|)^{\frac{1}{2}}}{\cosh(\pi t_j)} \sum_{N < n \leq 2N} a_n \rho_j(\pm n, a) \sqrt{n}, \\
\Sigma^{(2)}_{c,\pm}(N) &:= \frac{(1 + |t|)^{\frac{1}{2}}}{\cosh(\pi t)} \sum_{N < n \leq 2N} a_n \varphi_{c,\pm}(\pm n, a) \sqrt{n}, \\
\Sigma^{(3)}_{j,k}(N) &:= \sqrt{(k - 1)!} \sum_{N < n \leq 2N} a_n \psi_{j,k}(n, a) \sqrt{n}.
\end{align*}
\]

Then the following bounds are known as the large sieve inequalities.

**Theorem 2.6.** Let \( T \geq 1 \) and \( N \geq \frac{1}{2} \) be real numbers, \( a_n \) a sequence of complex numbers, and \( a \) a singular cusp of \( \Gamma \) written in the form \( a = \frac{a}{w} \) with \((u, w) = 1\). Then

\[
\begin{align*}
\sum_{|t_j| \leq T} \left| \Sigma^{(1)}_{j,\pm}(N) \right|^2 &\ll T^2 + q_0^{\frac{1}{2}} \left( w, \frac{q}{w} \right) \frac{N^{1+\varepsilon}}{q} \|a_n\|_N^2, \\
\sum_{c \, \text{sing.}} \int_{-T}^{T} \left| \Sigma^{(2)}_{c,\pm}(N) \right|^2 \, dt &\ll T^2 + q_0^{\frac{1}{2}} \left( w, \frac{q}{w} \right) \frac{N^{1+\varepsilon}}{q} \|a_n\|_N^2, \\
\sum_{k \leq T, k \equiv \pm 2 \pmod{q}} \left| \Sigma^{(3)}_{k,j}(N) \right|^2 &\ll T^2 + q_0^{\frac{1}{2}} \left( w, \frac{q}{w} \right) \frac{N^{1+\varepsilon}}{q} \|a_n\|_N^2,
\end{align*}
\]

where the implicit constants depend only on \( \varepsilon \).

**Proof.** With the appropriate changes, these bounds can be deduced essentially in the same way as it is done in [8, section 5]. We refer to [9] for details.

When there is no averaging over \( n \), the following lemma gives useful bounds, especially when \( q \) or \( T \) is large.

**Lemma 2.7.** Let \( T \geq 1 \), \( n \geq 1 \), and \( a \) as above. Then

\[
\begin{align*}
\sum_{|t_j| \leq T} \frac{(1 + |t_j|)^{\pm \kappa}}{\cosh(\pi t_j)} |\rho_j(\pm n, a)|^2 n &\ll T^2 + (qnT)^\varepsilon (q, n)^{\frac{1}{2}} q_0^{\frac{1}{2}} \left( w, \frac{q}{w} \right) \frac{n^{\frac{1}{2}}}{q}, \\
\sum_{c \, \text{sing.}} \int_{-T}^{T} \frac{(1 + |t|)^{\pm \kappa}}{\cosh(\pi t)} |\varphi_{c,\pm}(\pm n, a)|^2 n \, dt &\ll T^2 + (qnT)^\varepsilon (q, n)^{\frac{1}{2}} q_0^{\frac{1}{2}} \left( w, \frac{q}{w} \right) \frac{n^{\frac{1}{2}}}{q}, \\
\sum_{k \leq T, k \equiv \pm 2 \pmod{q}} \left( k - 1 \right)! |\psi_{j,k}(n, a)|^2 n &\ll T^2 + (qnT)^\varepsilon (q, n)^{\frac{1}{2}} q_0^{\frac{1}{2}} \left( w, \frac{q}{w} \right) \frac{n^{\frac{1}{2}}}{q},
\end{align*}
\]

where the implicit constants depend only on \( \varepsilon \).

**Proof.** For the full modular group and trivial nebentypus, a proof for the first two bounds can be found for example in [25, Lemma 2.4]. Using an appropriate trace formula as starting point (e.g. [12, Proposition 5.2]) , the proof carries over easily.
Lemma 2.9. The following result will turn out to be useful.

where the implicit constants depend only on $\varepsilon$.

Proof. For (2.7) we refer to [5, Lemma 1]. □

Proof. The bounds (2.6) and (2.8) can be proven along the lines of [23, Proposition 2.3]. For (2.7) we refer to [5, Lemma 1]. □

Finally, in order to handle exceptional eigenvalues, which occur in the case $\kappa = 0$, the following result will turn out to be useful.

Lemma 2.9. Let $X \geq 1$, $n \geq 1$ and $a$ as above. Assume that

$$X \gg X_0, \quad X_0 := \frac{q}{(q, n)^2 q_0^2 (w, \frac{q}{w}) n^2}.$$ 

Then

$$\sum_{t_j \text{ exc.}} |\rho_j(\pm n, a)|^2 n X^{4it_j} \ll (qnX)^{\varepsilon} \left( \frac{X}{X_0} \right)^{4\theta} \left( 1 + (q, n)^2 q_0^2 \left( \frac{w}{q}, \frac{q}{w} \right) n \frac{X}{q} \right),$$

where the implicit constants only depend on $\varepsilon$.

Proof. We have that

$$\sum_{t_j \text{ exc.}} |\rho_j(\pm n, a)|^2 n X^{4it_j} \ll \left( \frac{X}{X_0} \right)^{4\theta} \sum_{t_j \text{ exc.}} |\rho_j(\pm n, a)|^2 n \left( 1 + X_0 \right)^{4it_j}.$$ 

Now we use the fact that for any $Y \geq 1$,

$$\sum_{t_j \text{ exc.}} |\rho_j(\pm n, a)|^2 n X^{4it_j} \ll 1 + (qnY)^{\varepsilon} (q, n)^2 q_0^2 \left( \frac{w}{q}, \frac{q}{w} \right) n \frac{X}{q} Y,$$

which can be shown the same way as in [13, chapter 16.5], and the result follows. □

3. Proof of Theorems 1.1 and 1.2

Let $w_1, w_2 : (0, \infty) \to [0, \infty)$ be smooth functions, which are compactly supported in $[1/2, 1]$ and which satisfy

$$\frac{\partial^\nu w_1}{\partial \xi^\nu} (\xi) \ll \frac{1}{\Omega^\nu} \quad \text{and} \quad \int \frac{\partial^\nu w_1}{\partial \xi^\nu} (\xi) \, d\xi \ll \frac{1}{\Omega^{\nu-1}} \quad \text{for } \nu \geq 1,$$

for some $\Omega < 1$. We will look at the sum

$$D(x_1, x_2) := \sum_n w_1 \left( \frac{r_1 n + f_1}{x_1} \right) w_2 \left( \frac{r_2 n + f_2}{x_2} \right) d(r_1 n + f_1) d(r_2 n + f_2),$$

with the aim of showing that it can be written asymptotically as

$$D(x_1, x_2) = M(x_1, x_2) + R(x_1, x_2),$$

where $M(x_1, x_2)$ is a simpler variant of [8, Proposition 4].
where $M(x_1, x_2)$ denotes the main term, which has the form
\[
M(x_1, x_2) = \int_{\Omega} w_1 \left( \frac{r_1 \xi + f_1}{x_1} \right) w_2 \left( \frac{r_2 \xi + f_2}{x_2} \right) P(\log(r_1 \xi + f_1), \log(r_2 \xi + f_2)) \, d\xi
\]
(3.1)
with a quadratic polynomial $P(\xi_1, \xi_2)$, and where $R(x_1, x_2)$ forms the error term. The assumptions we hereby need to make are
\[
f_1 \ll x_1^{1-\epsilon}, \quad f_2 \ll x_2^{1-\epsilon} \quad \text{and} \quad h \ll r_2 x_1^{1-\epsilon} \Omega^2.
\]
(3.2)
We can also assume that
\[
r_0 r_1^2 x_2 \ll x_1,
\]
since otherwise our results are trivial. Furthermore note that from the first two bounds at (3.2) and the size of the supports of $w_1$ and $w_2$, it follows that
\[
r_2 x_1 \asymp r_1 x_2.
\]
We will prove the following three bounds for the error term:
\[
R(x_1, x_2) \ll r_0 (r_2 x_1)^{\frac{1}{2} + \epsilon} \left( \frac{|h|^\theta}{\Omega^2} + (r_2 x_1)^{\theta} \right),
\]
(3.3)
\[
R(x_1, x_2) \ll r_0 (r_2 x_1)^{\frac{3}{2} + \epsilon} \left( \frac{1}{\Omega^2} + \left( \frac{(r_0 r_1 r_2, h) x_1}{r_0 r_1^2 r_2} \right)^{\theta} \left( 1 + \left( \frac{(r_0 r_1 r_2, h)^{\frac{1}{2}} |h|^{\frac{1}{4}}}{r_0^{\frac{1}{2}} (r_1 r_2)^{\frac{1}{2}}} \right) \right) \right),
\]
(3.4)
\[
R(x_1, x_2) \ll r_0 (r_2 x_1)^{\frac{3}{2} + \epsilon} \left( \frac{1}{\Omega^2} + \left( \frac{r_2 x_1}{|h|} \right)^{\theta} \left( 1 + \left( \frac{(r_0 r_1 r_2, h)^{\frac{1}{2}} |h|^{\frac{1}{4}}}{r_0^{\frac{1}{2}} (r_1 r_2)^{\frac{1}{2}}} \right) \right) \right),
\]
(3.5)
Recall that $r_0$ was defined at (1.4). From the first bound and the choice $\Omega = 1$, we immediately get Theorem 1.1. In order to prove Theorem 1.2 we choose
\[
\Omega = \frac{r_0^{\frac{1}{2}} r_1^{\frac{2}{3}} r_2^{\frac{2}{3}}}{x_1^{\frac{1}{2}}},
\]
and use the second bound for
\[
(r_0 r_1 r_2, h) h \ll \left( \frac{r_1 r_2}{r_0} \right)^{\frac{1}{2}} \left( \frac{x_1}{r_1} \right)^{\frac{1}{2}} \left( \frac{r_0 r_1^2 r_2}{x_1} \right)^{4\theta},
\]
and the third bound for
\[
\left( \frac{r_1 r_2}{r_0} \right)^{\frac{1}{2}} \left( \frac{x_1}{r_1} \right)^{\frac{1}{2}} \left( \frac{r_0 r_1^2 r_2}{x_1} \right)^{4\theta} \ll (r_0 r_1 r_2, h) h \ll r_0^{\frac{1}{2}} r_1^{\frac{1}{2}} r_2^{\frac{1}{2}} x_1^{\frac{1}{2} + \epsilon}.
\]
This way we are led to
\[
R(x_1, x_2) \ll (r_0 r_1 r_2, h)^{\theta} r_0^{\frac{1}{2} + \epsilon} (r_1 r_2)^{\frac{1}{2}} \left( \frac{x_1}{r_1} \right)^{\frac{1}{2} + \epsilon},
\]
and Theorem 1.2 follows by setting $x_1 = r_1 x$, $x_2 = r_2 x$ and using suitable weight functions.

Before diving into the proof, we first want to describe a smooth decomposition of the divisor function which was used by Meurman to treat the binary additive divisor problem (and which originally goes back to Heath-Brown). Let $v_0 : \mathbb{R} \to [0, \infty)$ be a smooth and compactly supported function such that
\[
v_0(\xi) = 1 \quad \text{for} \quad |\xi| \leq 1, \quad \text{and} \quad v_0(\xi) = 0 \quad \text{for} \quad |\xi| \geq 2,
\]
and set
\[
v(\xi) := v_0 \left( \frac{\xi}{\sqrt{x_2}} \right) \quad \text{and} \quad h(a, b) := v(a)(2 - v(b)).
\]
For \( ab \leq x_2 \), we have that
\[
(v(a) - 1)(v(b) - 1) = 0,
\]
so that for \( n \leq x_2 \), it holds that
\[
d(n) = \sum_{ab=n} v(a)(2 - v(b)) = \sum_{ab=n} h(a, b).
\]

It will furthermore be helpful to dyadically split the supports of the variables \( a \) and \( b \). In order to do so, we choose smooth and compactly supported functions \( h_X : (0, \infty) \to [0, \infty) \), such that
\[
\text{supp } u_X \subset \left[ \frac{X}{2}, 2X \right], \quad \frac{\partial^\nu u_X}{\partial \xi^\nu}(\xi) \ll \frac{1}{X^\nu} \quad \text{and} \quad \sum_X u_X \equiv 1,
\]
where the last sum runs over powers of 2. Then we set
\[
h_{AB}(a, b) := h(a, b)u_A(a)u_B(b).
\]

Back to our sum – we split the second divisor function and use the dyadic decomposition described just before so that
\[
D(x_1, x_2) = \sum_{A, B} D_{AB}(x_1, x_2),
\]
where
\[
D_{AB}(x_1, x_2) := \sum_n w_1 \left( \frac{r_1 n + f_1}{x_1} \right) w_2 \left( \frac{r_2 n + f_2}{x_2} \right) d(r_1 n + f_1) \sum_{ab=r_2 n+f_2} h_{AB}(a, b)
\]
\[
= \sum_{ab=f_2 (r_2)} \tilde{f}(a, b) d\left( \frac{r_1}{r_2} (ab - f_2) + f_1 \right),
\]
and
\[
\tilde{f}(a, b) := w_1 \left( \frac{r_1}{r_2} (ab - f_2) + f_1 \right) w_2 \left( \frac{ab}{x_2} \right) h_{AB}(a, b).
\]

Note that the variables \( A \) and \( B \), which run over powers of 2, satisfy
\[
AB \asymp x_2, \quad A \ll B \quad \text{and} \quad A \ll x_2^{\frac{1}{2}}.
\]

In the following we have to pay a lot of attention to possible common divisors between the different parameters, and it will be helpful to define for \( i = 1, 2 \),
\[
u_i := (r_i, f_i), \quad s_i := \frac{r_i}{u_i}, \quad g_i := \frac{f_i}{u_i}, \quad \text{and} \quad h := r_1 f_2 - f_1 r_2, \quad h_0 := \frac{h}{u_1 u_2}.
\]

Now, since the product \( ab \) in the above sum must be divisible by \( u_2 \), we can write
\[
D_{AB}(x_1, x_2) = \sum_{u_2 | u_2} \sum_{a \leq u_2} \sum_{b \leq u_2} \tilde{f}\left( \frac{u_2 a}{u_2^2}, \frac{u_2 b}{u_2^2} \right) d\left( \frac{r_1}{u_2} (ab - g_2) + f_1 \right).
\]

Choose \( \tilde{a} \) and \( \tilde{s_2} \) such that
\[
\tilde{a} \tilde{a} + s_2 \tilde{s_2} = 1,
\]
so that \( b \) in the above sum has the form
\[
b = \tilde{a} g_2 + s_2 n \quad \text{with} \quad n \in \mathbb{Z},
\]
and hence

\[ D_{AB}(x_1, x_2) = \sum_{u_2 | u_2} \sum_{a \equiv \pm a_2 (u_2)} f \left( \frac{u_2 a}{u_2^2} \right) \left( \sum_{r_2} (an - g_2 \tilde{s}_2) + f_2 \right) d(n) f(n; a), \]

with

\[ f(\xi; a) := w_1 \left( \frac{\xi}{x_1} \right) w_2 \left( \frac{\xi - f_1}{x_2} \right) \frac{h_{AB} \left( \frac{u_2 a}{u_2^2} \right)}{\left( \frac{u_2 a}{u_2^2} \right)^{\nu_2}} \]

Note that the modular inverse \( \tilde{s}_2 \), which occurs in the congruence condition, is understood to be mod \( a \). Also note that the support of \( f(\xi; a) \) is given by

\[ \supp f(\bullet; a) \asymp x_1 \quad \text{and} \quad \supp f(\xi; \bullet) \asymp \frac{u_2^2}{u_2}, \]

and that its derivatives can be bounded by

\[ \frac{\partial^{\nu_1 + \nu_2} f}{\partial \xi^{\nu_1} a^{\nu_2}} (\xi; a) \ll \frac{1}{(x_1 \Omega)^{\nu_1}} \left( \frac{u_2}{u_2^2} \right)^{\nu_2} \quad \text{for} \quad \nu_1, \nu_2 \geq 0, \]

while also satisfying

\[ \int \left| \frac{\partial^{\nu_1 + \nu_2} f}{\partial \xi^{\nu_1} a^{\nu_2}} (\xi; a) \right| d\xi \ll \frac{1}{(x_1 \Omega)^{\nu_1 - 1}} \left( \frac{u_2}{u_2^2} \right)^{\nu_2} \quad \text{for} \quad \nu_1 \geq 1, \nu_2 \geq 0. \]

3.1. Use of Voronoi summation. We use Voronoi summation in the form of Theorem 2.11 to treat the divisor sum in arithmetic progressions. This way we are led to

\[ D_{AB}(x_1, x_2) = \Sigma^0_{AB} - 2\pi \Sigma^+_{AB} + 4\Sigma^-_{AB}, \]

with

\[ \Sigma^0_{AB} := \frac{1}{r_1} \sum_{u_2 | u_2} \sum_{a \equiv \pm a_2 (u_2)} \lambda_{f_1 - g_2 \tilde{s}_2, r_1, a} (\xi) f(\xi; a) d\xi, \]

\[ \Sigma^\pm_{AB} := \frac{1}{r_1} \sum_{u_2 | u_2} \sum_{c | r_1 a} \sum_{n=1}^\infty d(n) \frac{S(f_1 - g_2 \tilde{s}_2, \pm n; c)}{c^2} B^\pm \left( \frac{4\pi}{c} \sqrt{\xi} \right) f(\xi; a) d\xi, \]

and

\[ B^+ (\xi) := Y_0 (\xi) \quad \text{and} \quad B^- (\xi) := K_0 (\xi). \]

The main term will be extracted from \( \Sigma^0_{AB} \), but we will postpone this until the end and take care first of \( \Sigma^\pm_{AB} \).

We reshape these sums a little bit,

\[ \Sigma^\pm_{AB} = \frac{1}{r_1} \sum_{u_2 | u_2} \sum_{a \equiv \pm a_2 (u_2)} \sum_{c | r_1 a} \sum_{d \equiv \pm a_2 c (u_2)} \sum_{r_1 | d} \sum_{(c, s_2 u_2) = 1} \]

\[ = \frac{1}{r_1} \sum_{u_2 | u_2} \sum_{r_1 | d} \sum_{(c, s_2 u_2) = 1} \]

ON A CERTAIN ADDITIVE DIVISOR PROBLEM
where we have to replace $c$ by $r_1^* c$ and $a$ by $dc$, so that

$$\Sigma_{AB}^\pm = \sum_{d} \sum_{(c, s_2 u_2^*) = 1} \frac{R_{AB}^\pm}{d},$$

with

$$R_{AB}^\pm := \sum_{(c, s_2 u_2^*) = 1} \sum_{n=1}^{\infty} d(n) S(f_1 - g_2 r_1 s_2; \pm n; r_1^* c) F^\pm(r_1^* c; dc, n),$$

and

$$F^\pm(\eta; a, n) := \frac{r_1^*}{\eta^2} \int B^\pm \left( \frac{4\pi}{\eta} \sqrt{n^2 \xi^2} \right) f(\xi; a) d\xi.$$

As a reminder, the modular inverse $\frac{\eta}{n^2}$ occurring in the Kloosterman sum is now understood to be mod $dc$.

Let

$$N_0^- := \frac{x_1^*}{x_1} A^* s, \quad N_0^+ := \frac{x_1^*}{x_1} \Omega^2 A^* s, \quad \text{and} \quad A^* := \frac{u_2^* r_1^* A}{u_2^*}.$$

Regarding $F^\pm(r_1^* c; dc, n)$, we have the bounds

$$F^+(r_1^* d; dc, n) \ll \left( \frac{x_1^* \Omega^4}{n^2} \right) \left( \frac{A^*}{\sqrt{n^2 \eta^2}} \right)^{\nu - \frac{1}{2}},$$

$$F^-(r_1^* d; dc, n) \ll \left( \frac{x_1^* \Omega^4}{n^2} \right) \left( \frac{A^*}{\sqrt{n^2 \eta^2}} \right)^{\nu - \frac{1}{2}},$$

which can be shown using (2.2) resp. (2.1). With the help of these bounds, it is not hard to see that the sum over $n$ in $R_{AB}^\pm$ can be cut at $N_0^\pm$. After dyadically dividing the remaining sum, we are left with

$$R_{AB}^\pm(N) := \sum_{(c, s_2 u_2^*) = 1} \sum_{N < n \leq 2N} d(n) S(f_1 - g_2 r_1 s_2; \pm n; r_1^* c) F^\pm(r_1^* c; dc, n).$$

3.2. Treatment of the Kloosterman sums. Not surprisingly we would like to treat the sum of Kloosterman sums occurring in $R_{AB}^\pm(N)$ with the Kuznetsov trace formula. However, in our situation this does not seem to be possible directly. To deal with this difficulty, we factor out the part of the variable $r_1^*$ which has the same prime factors as $s_2 u_2^*$,

$$v := (r_1^*; s_2 u_2^*)^\infty, \quad t_1 := \frac{r_1^*}{v},$$

and use the twisted multiplicativity of Kloosterman sums,

$$\frac{S(f_1 - g_2 r_1 s_2; \pm n; r_1^* c)}{r_1^* c} = \frac{S(f_1 c t_1; \pm n c t_1; v)}{v} \frac{S(h_0 u_1; \pm n u_2^*; c t_1)}{c t_1}.$$

Here, all the modular inverses are finally understood to be modulo the respective modulus of the Kloosterman sum. Obviously the first factor still depends on $c$, but we follow an idea of Blomer and Mišičević and use Dirichlet characters to separate this variable. We define

$$\tilde{S}_c(\chi; n) := \sum_{y(v)} \chi(y) \frac{S(f_1 y; \pm n y, v)}{v},$$

and

$$\tilde{S}_c(\chi; n) := \sum_{y(v)} \chi(y) \frac{S(f_1 y; \pm n y, v)}{v},$$
where \( \chi \) is a Dirichlet character modulo \( v \), so that by the orthogonality relations of Dirichlet characters we have that
\[
\frac{S(f_1; \pm nct_1; v)}{v} = \frac{1}{\varphi(v)} \sum_{\chi \mod v} \overline{\chi}(ct_1) \hat{S}_v(\chi; n),
\]
where the sum runs over all Dirichlet characters modulo \( v \). Hence
\[
R_{AB}^\pm(N) = \frac{1}{\varphi(v)} \sum_{\chi \mod v} \overline{\chi}(t_1) R_{AB}^\pm(N; \chi),
\]
with
\[
R_{AB}^\pm(N; \chi) := \sum_{N < n \leq 2N} d(n) \hat{S}_v(\chi; n) K_{AB}^\pm(\chi; n),
\]
and
\[
K_{AB}^\pm(n; \chi) := \sum_{(\epsilon, s \epsilon^2_2) = 1} \frac{S(h_0 u_1 u_2^2 \pm n s_2 u_2^2 v^2; t_1 c)}{t_1 c} \chi^\epsilon t_1^\epsilon v^{\epsilon} R_{AB}^\pm(r_1^\epsilon c; dc, n).
\]

Of course it is important to have good bounds for \( \hat{S}_v(\chi; n) \). Directly using Weil’s bound for Kloosterman sums we get
\[
\hat{S}_v(\chi; n) \ll (f_1, n, v)^{1/2} v^{1/2 + \epsilon},
\]
however this can be improved with a little bit of effort. More precisely, we will prove
\[
\hat{S}_v(\chi; n) \ll \left( f_1, n, \frac{v}{\text{cond}(\chi)} \right) v^{\epsilon}, \quad (3.6)
\]
where \( \text{cond}(\chi) \) is the conductor of \( \chi \). The sum actually vanishes in a lot of cases, in particular when \( f_1, n \) and \( v \) have certain common factors, but this result will be sufficient for our purposes. At this point we also want to mention that
\[
\frac{1}{\varphi(v)} \sum_{\chi \mod v} \frac{v}{\text{cond}(\chi)} = \frac{v}{\varphi(v)} \sum_{\chi \mod v} \frac{1}{v^*} \sum_{\chi \mod v} \frac{1}{\varphi(v)} d(v) \ll v^{\epsilon}, \quad (3.7)
\]
which will be important later.

In order to prove (3.6), note first that \( \hat{S}_v(\chi; n) \) is quasi-multiplicative in the sense that if \( v = v_1 v_2 \) with coprime \( v_1 \) and \( v_2 \), and \( \chi = \chi_1 \chi_2 \) with the corresponding Dirichlet characters \( \chi_1 \) (mod \( v_1 \)) and \( \chi_2 \) (mod \( v_2 \)), then
\[
\hat{S}_v(\chi; n) = \chi_1(v_2) \chi_2(v_1) \hat{S}_{v_1}(\chi_1; n) \hat{S}_{v_2}(\chi_2; n).
\]
It is therefore enough to look at the case where \( v \) is a prime power \( v = p^k \).

Assume first that \( \chi = \chi_0 \) is the principal character. For \( v = p \) we have
\[
\hat{S}_p(\chi; n) = \frac{1}{p} \sum_{x \mod p} e\left( \frac{g(f_1 x \pm n \tau)}{p} \right) \varphi(p) = \sum_{x \mod p} \frac{1}{p} - \varphi(p) \ll (f_1, n, p),
\]
and for prime powers $v = p^k$, $k \geq 2$, we have
\[
\hat{S}_{p^k}(\chi; n) = \frac{1}{p^k} \sum_{x,y (p^k)} e\left(\frac{y(f_1x \pm n\overline{y})}{p^k}\right) - \frac{1}{p} \sum_{x (p^{k-1})} e\left(\frac{y(f_1x \pm n\overline{x})}{p^{k-1}}\right)
\]
\[
= \#\left\{x (p^k)|f_1x \pm n\overline{x} \equiv 0 (p^k)\right\} - \frac{1}{p}\#\left\{x (p^k)|f_1x \pm n\overline{x} \equiv 0 (p^{k-1})\right\}
\]
\[
\ll (f_1, n, p^k).
\]

In the following we can now assume that $\chi$ is non-principal. For $v = p$ prime this means that $\chi$ is primitive and hence
\[
\hat{S}_p(\chi; n) = \frac{1}{p} \sum_{x,y (p)} \chi(y)e\left(\frac{y(f_1x \pm n\overline{y})}{p}\right)
\]
\[
= \frac{1}{p} \sum_{x,y (p), f_1x \pm n\overline{y} \neq 0 (p)} \chi(y)\sqrt[p]{f_1x \pm n\overline{y}} e\left(\frac{y}{p}\right) - \frac{1}{p} \sum_{x,y (p), f_1x \pm n\overline{y} \equiv 0 (p)} \chi(y)
\]
\[
= \frac{\tau(\chi)}{p} \left(\sum_{x (p), (x,p)=1} \chi(f_1x \pm n\overline{x})\right)
\]
\[
\ll 1,
\]

where we have used the fact that both the Gauß sum $\tau(\chi)$ and the character sum on the right are bounded by $O(\sqrt{n})$, which is well-known for the former and follows from Weil’s work for the latter (see e.g. [15, Theorem 11.23] or [20, Chapter 6, Theorem 3]).

It remains to look at the case of $\chi$ having modulus $v = p^k$, $k \geq 2$, which is slightly more complicated. Let $\chi$ be induced by the primitive character $\chi^* = v^* = p^k$, and set $v^o := p^{k-k^*}$. In our sum
\[
\hat{S}_{p^k}(\chi; n) = \frac{1}{p^k} \sum_{x (p^k)} \sum_{y (p^k)} \chi(y)e\left(\frac{y(f_1x \pm n\overline{x})}{p^k}\right)
\]
we parametrize $y$ by
\[
y = y_1 + v^* y_2, \quad \text{with} \quad y_1 \mod v^* \quad \text{and} \quad y_2 \mod v^o.
\]

Then
\[
\hat{S}_{p^k}(\chi; n) = \frac{1}{v^*} \sum_{x (v)} \sum_{y_1 (v^*), f_1 x \pm n\overline{x} \equiv 0 (v^o)} \chi^*(y_1)e\left(\frac{y_1(f_1x \pm n\overline{x})}{v}\right) \sum_{y_2 (v^o)} e\left(\frac{y_2(f_1x \pm n\overline{x})}{v^o}\right)
\]
\[
= \frac{1}{v^*} \sum_{x (v), f_1 x \pm n\overline{x} \equiv 0 (v^o)} \sum_{y_1 (v^*)} \chi^*(y_1)e\left(\frac{y_1(f_1x \pm n\overline{x})}{v}\right)
\]
\[
= \frac{\tau(\chi^*)}{v^*} \sum_{x (v), f_1 x \pm n\overline{x} \equiv 0 (v^o)} \chi^*(f_1x \pm n\overline{x})
\]

We set
\[
\tilde{v}^o := \frac{v^o}{(f_1,n,v^o)}, \quad \tilde{v} := v^* \tilde{v}^o, \quad \tilde{f}_1 := \frac{f_1}{(f_1,n,v^o)} \quad \text{and} \quad \tilde{n} := \frac{n}{(f_1,n,v^o)}.
\]
and the sum becomes

\[ \hat{S}_{\mu^*}(\chi; n) = (f_1, n, \nu^0) \frac{\chi(x^*+\lambda)}{\nu^*} \sum_{x^*(\nu^0)} \chi \left( \frac{f_1 x + \nu^0}{\nu^*} \right). \]

If \( \tilde{\nu}^0 = 1 \), we have square-root cancellation for the character sum on the right (see [29, Theorem 2]), so that \( \hat{S}_{\mu^*}(\chi; n) \ll (f_1, n, \nu^0) \).

Otherwise note that both \( f_1 \) and \( \tilde{n} \) have to be coprime with \( p \), as otherwise the sum is empty. We parametrize \( x \) by

\[ x = x_1(1 + \tilde{\nu}^0 x_2), \quad \text{with} \quad x_1 \mod \tilde{\nu}^0, \quad (x_1, \tilde{\nu}^0) = 1 \] and \( x_2 \mod \nu^* \).

In this case we can write \( \nu^0 \) mod \( \tilde{\nu} \) in the following way

\[ \nu^0 \equiv \nu^0 \left( 1 - \tilde{\nu}^0 x_2 (1 + \tilde{\nu}^0 x_2) \right) \mod \tilde{\nu}, \]

and after putting this in our sum, we have

\[ \hat{S}_{\mu^*}(\chi; n) = (f_1, n, \nu^0) \frac{\chi(x^*)}{\nu^*} \sum_{x_1 (\nu^0)} \sum_{x_2 (\nu^*)} \chi^r (P(x_2)), \]

where \( P(X) \) is the rational function

\[ P(X) := \frac{f_1 x_1 \tilde{\nu}^0 X^2 + 2 f_1 x_1 X + f_1 x_1 + \nu^0}{\tilde{\nu}^0 X + 1}. \]

If \( p \geq 3 \), we can use [6, Theorem 1.1] to get that

\[ \sum_{x_2 (\nu^*)} \chi^r (P(x_2)) \ll 1. \]

If \( p = 2 \) and \( \tilde{\nu}^0 \geq 8 \), we rewrite this sum

\[ \sum_{x_2 (\nu^*)} \chi^r (P(x_2)) = \sum_{x_2 (2\nu^*)} \chi^r \left( P \left( \frac{T_2}{2} \right) \right) = 2 \sum_{x_2 (\nu^*)} \chi^r \left( P \left( \frac{T_2}{2} \right) \right), \]

so that we can again apply the cited theorem to show that this sum is \( O(1) \). Finally for the remaining cases \( \tilde{\nu}^0 = 2 \) and \( \tilde{\nu}^0 = 4 \), we can use [6, Theorem 2.1] to show square-root cancellation. This concludes the proof of (3.6).

3.3. Auxiliary estimates. We want to use the Kuznetsov trace formula in the form (2.3) with

\[ \hat{q} := t_1 s_2 u_2^2 v^2, \quad \hat{r} := s_2 u_2^2 v^2, \quad \hat{s} := t_1, \quad \hat{q}_0 := v, \quad \hat{n} := h_0 u_1 u_2^2, \quad \hat{n} := n. \]

However, before we can do so some technical arrangements have to be made. Set

\[ F_{\pm}(c; n) := h(n) \frac{v}{r_1} \sqrt{s_2 u_2^2} \sqrt{\frac{r_2}{n|h|}} \int eB^{\pm} \left( c \sqrt{\frac{T_2}{|h|}} \right) f \left( \frac{\xi}{r_1}, \frac{d\sqrt{n}}{r_1 c} \sqrt{\frac{|h|}{r_2}} \right) d\xi, \]

where \( h \) is a smooth and compactly supported bump function such that

\[ h(n) = 1 \quad \text{for} \quad n \in [N, 2N], \quad \supp h \sim N \quad \text{and} \quad h^{(\nu)}(n) \ll \frac{1}{N^\nu}. \]

We have defined this function in such a way that

\[ F_{\pm}(r_1^*; dc, n) = \frac{1}{\sqrt{r}} F_{\pm} \left( \frac{4\pi \sqrt{|hn|}}{\sqrt{r} \hat{s} c}; n \right) \quad \text{for} \quad n \in [N, 2N]. \]
Note that

\[ \text{supp} \hat{F}^\pm(\bullet; n) = C := \frac{1}{A^*} \sqrt{\frac{|h|}{r_2}}, \quad \hat{F}^\pm(c; n) \ll \nu \sqrt{s_2 u_2} \frac{r_1}{A^* r_1} x_1^{1+\varepsilon}. \]

We need to separate the variable \( n \) to be able to use the large sieve inequalities later, and to this end we make use of Fourier inversion,

\[ \hat{F}^\pm(c; n) = \int G_0(\lambda) G^\pm_\lambda(c) e(\lambda n) \, d\lambda, \quad G^\pm_\lambda(c) := \frac{1}{G_0(\lambda)} \int \hat{F}^\pm(c; n) e(-\lambda n) \, dn, \]

where

\[ G_0(\lambda) := \nu \sqrt{s_2 u_2} \frac{r_1}{A^* r_1} x_1^{1+\varepsilon} \min\left( N, \frac{1}{N^2} \right). \]

Eventually, our sum of Kloosterman sums looks like

\[ K^\pm_{AB}(\chi; n) := \int G_0(\lambda) e(\lambda n) \sum_{(c, \tilde{c})=1} \overline{\chi(c)} \frac{S(\tilde{m}, \pm \tilde{n} r; \tilde{s} \tilde{c})}{c \sqrt{s}} \tilde{G}^\pm_\lambda \left( 4\pi \sqrt{\overline{\tilde{m}} \tilde{n}} \right) \, d\lambda. \]

Next, we need to find good estimates for the Bessel transforms occurring in the Kuznetsov formula. For convenience set

\[ C := \frac{1}{A^*} \sqrt{\frac{|h| N}{r_2}} \quad \text{and} \quad Z := \frac{1}{A^*} \sqrt{x_1 N}. \]

Note that due to the assumptions made at (3.2), it is true that \( C \ll 1 \).

**Lemma 3.1.** If \( N \ll N_0^- \), we have

\[ \hat{G}^\pm_\lambda(it), \hat{G}^\pm_\lambda(it) \ll C^{-2t} \quad \text{for} \quad 0 \leq t < \frac{1}{4}, \quad (3.8) \]

\[ \frac{\hat{G}^\pm_\lambda(t)}{(1 + t)^n}, \frac{\hat{G}^\pm_\lambda(t)}{(1 + t)^n} \ll \frac{x_1^\varepsilon}{1 + t^n} \quad \text{for} \quad t \geq 0. \quad (3.9) \]

If \( N_0^- \ll N \ll N_0^+ \), we have for any \( \nu \geq 0 \),

\[ \hat{G}^\pm_\lambda(it), \hat{G}^\pm_\lambda(it) \ll x_1^{-\nu} \quad \text{for} \quad 0 \leq t < \frac{1}{4}, \quad (3.10) \]

\[ \frac{\hat{G}^\pm_\lambda(t)}{(1 + t)^n}, \frac{\hat{G}^\pm_\lambda(t)}{(1 + t)^n} \ll \frac{x_1^\varepsilon (Z^2 \lambda / t)^\nu}{Z^2 \lambda / t} \quad \text{for} \quad t \geq 0. \quad (3.11) \]

**Proof.** Since all occurring integrals can be interchanged, we can look directly at the Bessel transforms inside \( \hat{F}^\pm(c, n) \) and their first two partial derivatives in \( n \). We will confine ourselves with the treatment of \( \hat{F}^\pm(c, n) \), since the corresponding estimates for the derivatives can be shown the same way.

First we want to prove the first two bounds, which hold when \( N \ll N_0^- \). Here again, we can look directly at the function inside the integral over \( \xi \), given by

\[ H_1(c) := c B^\pm \left( c \sqrt{\frac{\xi r_2}{|h|}} \right) f \left( \xi; 4\pi \frac{\frac{n|h|}{r_2} c}{r_1^*} \right). \]

We have that

\[ \text{supp} H_1 = C \quad \text{and} \quad H_1^{(o)}(c) \ll x_1^\varepsilon C \left( \frac{x_1^\varepsilon}{C} \right)^\nu, \]

so that by Lemma 2.4,

\[ \hat{H}^\pm_\lambda(it), \hat{H}^\pm_\lambda(it) \ll C^{1-2t} \quad \text{for} \quad 0 \leq t < \frac{1}{4}, \]

\[ \frac{\hat{H}^\pm_\lambda(t)}{(1 + t)^n}, \frac{\hat{H}^\pm_\lambda(t)}{(1 + t)^n} \ll \frac{x_1^\varepsilon C}{1 + t^n} \quad \text{for} \quad t \geq 0, \]
from which we get (3.8) and (3.9).

Now assume $N_0^- < N < N_0^+$. By using Lemma 2.2 and partially integrating once over $\xi$, we get

$$\tilde{F}^\pm(c) = \frac{1}{\pi} \frac{h(u)}{\sqrt{n}} \frac{r_1^* v \sqrt{s_2 u_2}}{r_2} \Im \left( \int e \left( \frac{c}{2\pi} \sqrt{\frac{\xi \tilde{r}_2}{|h|}} \right) \tilde{w}(c) d\xi \right)$$

with

$$\tilde{w}(c) := \frac{\partial}{\partial \xi} \left( \sqrt{\xi \tilde{r}_2} \left( \frac{c}{\pi} \sqrt{\frac{\xi \tilde{r}_2}{|h|}} \right) f \left( \xi; 4\pi \frac{d}{r_2^2 c} \frac{|n| |h|}{r_2} \right) \right).$$

It is hence enough to look at $H_2(c) := e \left( \frac{c}{2\pi} \sqrt{\frac{\xi \tilde{r}_2}{|h|}} \right) \tilde{w}(c)$.

Note that

$$\text{supp } \tilde{w} \subset C, \quad \text{and } \tilde{w}(c) \ll \frac{\omega(\xi)}{x_1^2 Z^2 C},$$

where

$$\omega(\xi) := 1 + \left| w_1' \left( \frac{\xi}{x_1} \right) \right| + \left| w_2' \left( \frac{r_2 (\xi - f_1) + f_2}{x_2} \right) \right|.$$

Here we use Lemma 2.3 with $\alpha = \sqrt{\frac{\xi \tilde{r}_2}{|h|}}$ and $X = C$. This is possible as

$$\alpha X \gg \frac{(x_1 N_0^-)^\frac{1}{2}}{A^*} \gg x_1^{\frac{1}{4}},$$

and we get

$$\tilde{H}_\chi^\pm(it), \tilde{H}_\lambda^\pm(it) \ll x_1^{-\nu} \quad \text{for } 0 \leq t < \frac{1}{4},$$

$$\tilde{H}_\chi^\pm\tilde{\chi}(t), \tilde{H}_\chi^\pm\tilde{\chi}(t) \ll x_1^{\epsilon} Z^2 \left( \frac{Z}{t} \right)^{\nu} \quad \text{for } t \geq 0,$$

and 3.10 and 3.11 follow immediately. \qed

3.4. Use of the Kuznetsov trace formula. Here we will only look at $K_{AB}^\chi(\chi; n)$ and we will assume that $h > 0$, since all other cases can be treated in essentially the same way.

A use of Theorem 2.3 gives

$$R_{AB}^\chi(N; \chi) = \int G_0(\lambda) (\Xi_1(\lambda) + \Xi_2(\lambda) + \Xi_3(\lambda)) d\lambda,$$

where

$$\Xi_1(\lambda) := \sum_{j=1}^{\infty} \frac{\tilde{G}_\chi^+(t_j)}{(1 + |t_j|)^{\nu}} \frac{(1 + |t_j|)^\frac{\nu}{2}}{\sqrt{\cosh(\pi t_j)}} \left( \sqrt{m} \right)^{\frac{\nu}{2}} \Sigma_{j,1}^{(1)}(N),$$

$$\Xi_2(\lambda) := \sum_{\epsilon \text{ sing.}} \frac{1}{1 + |t_j|^\nu} \int_{-\infty}^{\infty} \frac{\tilde{G}_\chi^+(r)}{(1 + |t_j|)^{\nu}} \frac{(1 + |t_j|)^\frac{\nu}{2}}{\sqrt{\cosh(\pi r)}} \left( \sqrt{m} \right)^{\frac{\nu}{2}} \Sigma_{j,2}^{(2)}(N) dr,$$

$$\Xi_3(\lambda) := \sum_{k \equiv \chi(2), \ k > \lambda} \frac{\tilde{G}_\chi^+(k)}{(1 + |t_j|)^{\nu}} \frac{(1 + |t_j|)^\frac{\nu}{2}}{\sqrt{\cosh(\pi r)}} \left( \sqrt{m} \right)^{\frac{\nu}{2}} \Sigma_{j,k}^{(3)}(N),$$

for $1 \leq j \leq \theta_\chi(q, \lambda)$. 

ON A CERTAIN ADDITIVE DIVISOR PROBLEM 19
and in the same way as above we can show that

\[ \Sigma_{j}^{(1)}(N) := \left( \frac{1 + |t_j|}{\cosh(\pi t_j)} \right) \sum_{N < n < 2N} d(n) \tilde{S}_e(\bar{\chi}_n) e\left( \lambda n - \frac{\tilde{r}_j}{\tilde{r}_j} \right) \rho_j \left( n, \frac{1}{8} \right) \sqrt{n}, \]

\[ \Sigma_{j}^{(2)}(N) := \left( \frac{1 + |t|}{\cosh(\pi t)} \right) \sum_{N < n < 2N} d(n) \tilde{S}_e(\bar{\chi}_n) e\left( \lambda n - \frac{\tilde{r}_j}{\tilde{r}_j} \right) \tilde{\varphi}_{\epsilon, r} \left( n, \frac{1}{8} \right) \sqrt{n}, \]

\[ \Sigma_{j}^{(3)}(N) := \sqrt{(k - 1)!} \sum_{N < n < 2N} d(n) \tilde{S}_e(\bar{\chi}_n) e\left( \lambda n - \frac{\tilde{r}_j}{\tilde{r}_j} \right) \psi_{j,k} \left( n, \frac{1}{8} \right) \sqrt{n}. \]

Assume first that \( N \ll N_0 \). We divide \( \Xi_{1}(N) \) into three parts:

\[ \Xi_{1}(N) = \sum_{j \leq N} (\ldots) + \sum_{j > N} (\ldots) + \sum_{j \text{ exc.}} (\ldots) := \Xi_{1a}(N) + \Xi_{1b}(N) + \Xi_{1c}(N). \]

We use Cauchy-Schwarz on \( \Xi_{1a}(N) \), and then Lemma 3.1 Theorem 2.6 and Lemma 2.8 to bound the different factors, which leads to

\[ \Xi_{1a}(N) \leq \max_{t_j \leq N} \left( \frac{\tilde{\varphi}_{\epsilon, r}(t)}{\cosh(\pi t_j)} \right) \left( \sum_{N < n < 2N} \left( \frac{1 + |t_j|}{\cosh(\pi t_j)} \right) \left| \rho_j(n, \frac{1}{8}) \right|^2 \right)^{\frac{1}{2}} \left( \sum_{N < n < 2N} |\Xi_{j}^{(1)}(N)|^2 \right)^{\frac{1}{2}} \]

\[ \ll x_1^3 \tilde{m}^4 \left( 1 + \frac{\tilde{r}_j}{\tilde{r}_j} \right) \left( \sum_{N < n < 2N} \left( f_1(n, \frac{1}{8}) \right)^2 \right) \]

\[ \ll v^{3/2} x_1^4 x_1^{\theta} A^* \left( x_1^4 + \frac{A^*}{v^4 (r_1 s_2 u_2^2)^2} \right), \]

where we have set

\[ v^\alpha := \frac{v}{\cond(\chi)}. \]

We split up \( \Xi_{1b}(N) \) into dyadic segments

\[ \Xi_{1b}(N, T) := \sum_{T < t_j \leq 2T} \frac{\tilde{\varphi}_{\epsilon, r}(t_j)}{\sqrt{\cosh(\pi t_j)}} \sqrt{\tilde{m}} \Xi_{j}^{(1)}(N), \]

and in the same way as above we can show that

\[ \Xi_{1b}(N, T) \ll v^{3/2} x_1^4 x_1^{\theta} A^* \left( x_1^4 + \frac{A^*}{v^4 (r_1 s_2 u_2^2)^2} \right), \]

which gives the same bound for \( \Xi_{1b}(N) \) as for \( \Xi_{1a}(N) \). Finally, for \( \Xi_{1c} \) we get

\[ \Xi_{1c}(N) \ll v^{3/2} x_1^4 (r_2 x_1^2) A^* \left( x_1^4 + \frac{A^*}{v^4 (r_1 s_2 u_2^2)^2} \right), \]

and all in all this leads to

\[ \int G_0(\lambda) \Xi_{1}(N) d\lambda \ll v^{3/2} v(r_2 x_1) \frac{1}{t^\theta + \epsilon}. \]  

(3.12)

In exactly the same manner, but using Lemma 2.7 instead of Lemma 2.8 we can also get the bounds

\[ \Xi_{1a}(N), \Xi_{1b}(N) \ll v^{3/2} x_1^4 A^* \left( x_1^4 + \frac{A^*}{v^4 (r_1 s_2 u_2^2)^2} \right) \left( 1 + \frac{(r_1^2 r_2 v, h) t^2}{(r_1^2 r_2)^2 v^2} \right), \]

and

\[ \Xi_{1c}(N) \ll v^{3/2} x_1^4 \left( \frac{r_2 x_1^2}{h} \right)^\theta A^* \left( x_1^4 + \frac{A^*}{v^4 (r_1 s_2 u_2^2)^2} \right) \left( 1 + \frac{(r_1^2 r_2 v, h) t^2}{(r_1^2 r_2)^2 v^2} \right), \]
so that
\[ \int G_0(\lambda)\Xi_1(N) \, d\lambda \ll v^{\frac{\theta}{2}} v(r_2 x_1)^{\frac{\theta}{2} + \varepsilon} \left( \frac{r_2 x_1}{h} \right)^{\theta} \left( 1 + \frac{(r_1 r_2 v, h)}{(r_1 r_2)^{\frac{\theta}{2} + \frac{\varepsilon}{2}}} \right). \] (3.13)

Furthermore since
\[ \frac{x_1^e}{c} \gg \frac{x_1^{\frac{\theta}{2} + \varepsilon}}{h^{\frac{\theta}{2}}} \gg \frac{r_1 r_2 v^{\frac{\theta}{2}}}{(r_1 r_2 v, h)^{\frac{\theta}{2} + \varepsilon}} = \frac{\tilde{q}}{(\tilde{q}, \tilde{m})^{\frac{\theta}{2} + \varepsilon} \tilde{m}^{\frac{\theta}{2}}}, \]
we can also make use of Lemma 2.9 here, so that
\[ \Xi_{1e}(N) \ll \left( \sum_{t_j \leq 1} \frac{|\rho_j(\tilde{m}, \infty)|^2 \tilde{m} \left( \frac{x_1^e}{c} \right)^4}{\cosh(\pi t_j)} \right)^{\frac{1}{2}} \left( \sum_{t_j \leq 1} |\Sigma_j^{(1)}(N)|^2 \right)^{\frac{1}{2}} \ll v^{\theta} x_1^{\theta + \varepsilon} (r_1 r_2 v, h)^{\theta} \frac{A_1^*}{v^{\frac{\theta}{2}} (r_1 r_2 v, h)^{\frac{\theta}{2} + \varepsilon}} \left( 1 + \frac{(r_1 r_2 v, h)}{(r_1 r_2)^{\frac{\theta}{2} + \frac{\varepsilon}{2}}} \right), \]
and hence
\[ \int G_0(\lambda)\Xi_1(N) \, d\lambda \ll v^{\theta} v(r_2 x_1)^{\frac{\theta}{2} + \varepsilon} \left( x_1 \frac{(r_1 r_2 v, h)}{r_1 r_2 v} \right)^{\theta} \left( 1 + \frac{(r_1 r_2 v, h)}{(r_1 r_2)^{\frac{\theta}{2} + \frac{\varepsilon}{2}}} \right). \] (3.14)

Now assume \( N_1^{-} \ll N \ll N_1^{+} \). We split \( \Xi_1(N) \) into three parts as follows,
\[ \Xi_1(N) = \sum_{t_j \leq 2} \ldots + \sum_{t_j > Z} \ldots + \sum_{t_j \text{ exc.}} \ldots. \]

The sum over the exceptional eigenvalues causes no problems in this case, as the respective Bessel transforms are very small. The rest can be treated in the same way as above, and we get the bounds
\[ \int G_0(\lambda)\Xi_1(N) \, d\lambda \ll v^{\frac{\theta}{2}} v(r_2 x_1)^{\frac{\theta}{2} + \varepsilon} \frac{h^{\theta}}{\Omega^{\frac{\theta}{2}}} \] (3.15)
\[ \int G_0(\lambda)\Xi_1(N) \, d\lambda \ll v^{\frac{\theta}{2}} v(r_2 x_1)^{\frac{\theta}{2} + \varepsilon} \frac{1}{\Omega} \left( 1 + \Omega^{\frac{1}{2}} \frac{(r_1 r_2 v, h)}{(r_1 r_2)^{\frac{\theta}{2} + \frac{\varepsilon}{2}}} \right). \] (3.16)

The same reasoning applies similarly to \( \Xi_2(N) \) and \( \Xi_3(N) \), the main difference being that we don’t have to worry about exceptional eigenvalues at all. In the end we get from (3.12) and (3.13),
\[ R_{AB}^+(N; \chi) \ll v^{\frac{\theta}{2}} v(r_2 x_1)^{\frac{\theta}{2} + \varepsilon} \left( \frac{h^{\theta}}{\Omega^{\frac{\theta}{2}}} + (r_2 x_1)^{\theta} \right), \]
from (3.14) and (3.16),
\[ R_{AB}^+(N; \chi) \ll v^{\frac{\theta}{2}} v(r_2 x_1)^{\frac{\theta}{2} + \varepsilon} \left( \frac{1}{\Omega} + \frac{x_1 (r_1 r_2 v, h)}{r_1 r_2 v} \right)^{\theta} \left( 1 + \frac{(r_1 r_2 v, h)}{(r_1 r_2)^{\frac{\theta}{2} + \frac{\varepsilon}{2}}} \right), \]
and from (3.13) and (3.16),
\[ R_{AB}^+(N; \chi) \ll v^{\frac{\theta}{2}} v(r_2 x_1)^{\frac{\theta}{2} + \varepsilon} \left( \frac{1}{\Omega} + \frac{(r_2 x_1)^{\theta}}{h} \right)^{\theta} \left( 1 + \frac{(r_1 r_2 v, h)}{(r_1 r_2)^{\frac{\theta}{2} + \frac{\varepsilon}{2}}} \right). \]

Taking account of (3.7), these bounds eventually lead to (3.8), (3.14) and (3.15).
3.5. **The main term.** The only thing left to do is the evaluation of the main term. After summing over all \(A\) and \(B\), it has the form

\[
\Sigma^0 := \frac{1}{r_1} \sum_{u_2^2|w_2} \sum_{(a,s_2 u_2^2)=1} \frac{1}{a} \int \lambda_{f_1-r_1 g_2 r_1 a}(\xi) f(\xi; a) d\xi
\]

\[
= \int w_1 \left( \frac{r_1 \xi + f_1}{x_1} \right) w_2 \left( \frac{r_2 \xi + f_2}{x_2} \right) \left( \sum_{u_2|w_2} \Sigma^0(\xi, u_2^*) \right) d\xi,
\]

(3.17)

with

\[
\Sigma^0(\xi, u_2^*) := \sum_{(a,s_2 u_2^2)=1} \frac{\lambda_{f_1-r_1 g_2 r_1 a}(r_1 \xi + f_1)}{a} \left( \frac{u_2 a^2}{u_2^*} \frac{u_2^*}{u_2 a^2} (r_2 \xi + f_2) \right)
\]

\[
= \frac{1}{2\pi i} \int_{(\sigma)} \hat{h}(s; \xi) Z(s; \xi) ds,
\]

(3.18)

where \(\hat{h}(s; \xi)\) is the Mellin transform

\[
\hat{h}(s; \xi) := \int_0^\infty \left( \frac{u_2 a^2}{u_2^*} \frac{u_2^*}{u_2 a^2} (r_2 \xi + f_2) \right)^{s-1} da, \quad \text{Re}(s) > 0,
\]

and the function \(Z(s; \xi)\) is defined as the Dirichlet series

\[
Z(s; \xi) := \sum_{(a,s_2 u_2^2)=1} \frac{\lambda_{f_1-r_1 g_2 r_1 a}(r_1 \xi + f_1)}{a^{1+s}}, \quad \text{Re}(s) > 0.
\]

The integral in (3.18) is initially defined for \(\sigma > 0\). Our plan is to move the line of integration to \(\sigma = -1 + \varepsilon\), so that we can use the residue theorem to extract a main term. A meromorphic continuation of \(\hat{h}(s; \xi)\) can easily be found by using partial integration. For \(Z(s; \xi)\) the situation is not quite as obvious.

Define the operator

\[
\Delta_\delta(\xi) := \left( \log \xi + 2\gamma + \frac{\partial}{\partial \delta} \right)|_{\delta = 0},
\]

so that we can write

\[
\lambda_{f_1-r_1 g_2 r_1 a}(r_1 \xi + f_1) = \Delta_\delta(r_1 \xi + f_1) \sum_{d|r_1 a} \frac{c_d(f_1 - r_1 g_2 \xi)}{d^{1+\delta}}.
\]

Now we separate the part of \(r_1\) which shares common factors with \(s_2 u_2^2\) from the rest by setting

\[
v := (r_1, (s_2 u_2^2)\infty), \quad t_1 := \frac{r_1}{v},
\]

so that

\[
\sum_{d|r_1 a} \frac{c_d(f_1 - r_1 g_2 \xi)}{d^{1+\delta}} = \left( \sum_{d|v} \frac{c_d(f_1)}{d^{1+\delta}} \right) \left( \sum_{d|t_1 a} \frac{c_d(h_0 u_1)}{d^{1+\delta}} \right),
\]

and hence

\[
Z(s; \xi) = \Delta_\delta(r_1 \xi + f_1) \left( \sum_{d|v} \frac{c_d(f_1)}{d^{1+\delta}} \right) \sum_{(a,s_2 u_2^2)=1} \frac{1}{a^{1+s}} \sum_{d|t_1 a} \frac{c_d(h_0 u_1)}{d^{1+\delta}}.
\]

The two outer sums can be transformed to

\[
\sum_{(a,s_2 u_2^2)=1} \frac{1}{a^{1+s}} \sum_{d|t_1 a} \frac{c_d(h_0 u_1)}{d^{1+\delta}} = \sum_{d} \frac{c_d(h_0 u_1)(d, t_1)}{d^{2+\delta}} \bar{Z}(s; d),
\]

where
with
\[ \tilde{Z}(s; d) := \zeta(1 + s) \frac{(d, t_1)^s}{d^s} \prod_{p \mid s^2 u_2^2} \left( 1 - \frac{1}{p^{1+s}} \right). \]

This is a meromorphic function, defined on the whole complex plane, which means that the desired meromorphic continuation for \( Z(s; \xi) \) can be given by

\[ Z(s; \xi) = \Delta_\delta(r_1 \xi + f_1) \left( \sum_{d \mid u} \frac{c_d(f_1)}{d^{1+s}} \right) \left( \sum_{d \in (d, s_2 u_2^2) = 1} \frac{c_d(h_0 u_1)(d, t_1)}{d^{2+s}} \tilde{Z}(s; d) \right). \]

Hence

\[ \tilde{\Sigma}^0_\xi(u_2^2) = \Delta_\delta(r_1 \xi + f_1) \left( \sum_{d \mid u} \frac{c_d(f_1)}{d^{1+s}} \right) \left( \sum_{d \in (d, s_2 u_2^2) = 1} \frac{c_d(h_0 u_1)(d, t_1)}{d^{2+s}} \tilde{Z}(s; d) \right), \]

with

\[ \tilde{P}^0(\xi, d) := \frac{1}{2\pi i} \int_{(\sigma)} \hat{h}(s; \xi) \tilde{Z}(s; d) \, ds. \]

The Mellin transform \( \hat{h}(s; \xi) \) has at \( s = 0 \) the Taylor expansion

\[ \hat{h}(s; \xi) = \frac{2}{s} + \log(r_2 \xi + f_2) + 2 \log \frac{u_2^2}{u_2} + O(s), \]

while that of \( \tilde{Z}(s; d) \) is given by

\[ \tilde{Z}(s; d) = \left( \frac{1}{s} + \gamma + \frac{\partial}{\partial s} \right) \left( \frac{(d, t_1)^s}{d^s} \prod_{p \mid s^2 u_2^2} \left( 1 - \frac{1}{p^{1+s}} \right) \right) + O(s). \]

All in all, the residue of their product at \( s = 0 \) is

\[ \text{Res}_{s=0} \left( \hat{h}(s; \xi) \tilde{Z}(s; d) \right) = \Delta_\delta(r_2 \xi + f_2) \left( \frac{u_2^2}{u_2} \right)^\rho \left( \frac{(d, t_1)^s}{d^s} \prod_{p \mid s^2 u_2^2} \left( 1 - \frac{1}{p^{1+s}} \right) \right). \]

We now move the line of integration to \( \sigma = -1 + \varepsilon, \)

\[ \tilde{P}^0(\xi, d) = \Delta_\delta(r_2 \xi + f_2) \left( \frac{u_2^2}{u_2} \right)^\rho \left( \frac{(d, t_1)^s}{d^s} \prod_{p \mid s^2 u_2^2} \left( 1 - \frac{1}{p^{1+s}} \right) \right) + O \left( \frac{d^{1-\varepsilon}}{s_2^{\frac{\varepsilon}{2}} - \varepsilon} \right), \]

and hence

\[ \tilde{\Sigma}^0_{\Delta_\delta}(\xi, u_2^2) = \Delta_\delta(r_1 \xi + f_1) \Delta_\delta(r_2 \xi + f_2) \tilde{M}^0_{\delta, \rho}(\xi, u_2^2) + O \left( \frac{x_2^{\varepsilon}}{x_2^{\frac{\varepsilon}{2}}} \right), \]

with

\[ \tilde{M}^0_{\delta, \rho}(\xi, u_2^2) := \left( \frac{u_2^2}{u_2} \right)^\rho \left( \sum_{d \mid u} \frac{c_d(f_1)}{d^{1+s}} \prod_{p \mid s^2 u_2^2} \left( 1 - \frac{1}{p^{1+s}} \right) \right), \]

An elementary but quite tedious calculation shows that this product can be transformed in such a way that

\[ \sum_{u_2 \mid u_2} \tilde{M}^0_{\delta, \rho}(\xi, u_2^2) = C_{\delta, \rho}(r_1, r_2, f_1, f_2), \]
where
\[ C_{\delta, \rho}(r_1, r_2, f_1, f_2) := \sum_{u_1 | u \atop w_1 | w \atop u_2 | u} \left( \frac{u_1}{u} \right)^{\delta} \left( \frac{u_2}{u} \right)^{\rho} \psi_{\delta}(s_1 u_1^*) \psi_{\rho}(s_2 u_2^*) \gamma_{\delta + \rho}(s_1 u_1^* s_2 u_2^*), \]
with
\[ \psi_\alpha(n) := \prod_{p \mid n} \left( 1 - \frac{1}{p^{1+\alpha}} \right) \quad \text{and} \quad \gamma_\alpha(n) := \sum_{(d,n)=1} \frac{c_d(h_0)}{d^{2+\alpha}}. \]

After a look back at (3.17), we see that our main term has the form
\[ \Sigma^0 = M(x_1, x_2) + \mathcal{O}\left( \frac{x_1^{\frac{3}{2}+\varepsilon}}{x_2} \right), \]
with
\[ M(x_1, x_2) := \int w_1 \left( \frac{r_1 \xi + f_1}{x_1} \right) w_2 \left( \frac{r_2 \xi + f_2}{x_2} \right) P(\log(r_1 \xi + f_1), \log(r_2 \xi + f_2)) d\xi, \]
where \( P(\xi_1, \xi_2) \) is the quadratic polynomial given by
\[ P(\log \xi_1, \log \xi_2) := \Delta_4(\xi_1) \Delta_6(\xi_2) C_{\delta, \rho}(r_1, r_2, f_1, f_2). \]

(3.19)

This concludes the proof of 5.11.
