Abstract

We analytically determine the minimal time and the optimal control laws required for the realization, up to an assigned fidelity and with a fixed energy available, of entangling quantum gates (CNOT) between indirectly coupled qubits of a trilinear Ising chain. The control is coherent and open loop, and it is represented by a local and continuous magnetic field acting on the intermediate qubit. The time cost of this local quantum operation is not restricted to be zero. When the matching with the target gate is perfect (fidelity equal to 1), we provide exact solutions for the case of equal Ising coupling. For the more general case when some error is tolerated (fidelity smaller than 1), we give perturbative solutions for unequal couplings. Comparison with previous numerical solutions for the minimal time to generate the same gates with the same Ising Hamiltonian but with instantaneous local controls shows that the latter are not time optimal.

1. Introduction

Time-optimal control is an active branch of the wider arena of quantum control. Quantum control has been successfully applied to a series of physical problems, e.g., molecular dynamics [1], quantum information [2, 3] and multidimensional advanced spectroscopy techniques in nuclear magnetic resonance (NMR) experiments [4]. Time-optimal quantum computing aims at minimizing the time cost to achieve a certain target. It may be of relevance both from the theoretical point of view, e.g., in order to determine the fundamental maximal speed at which quantum information may be transported [5–8], to find out faster quantum algorithms and solve complex problems [10], or it may serve more practical but essential purposes such as...
determining the fastest way to realize a certain unitary gate before the ubiquitous decoherence effects disrupt the computation and, in general, to define a more physical meaning to the complexity of quantum algorithms [11]. The results published in time-optimal quantum control are numerous and it is certainly not the scope of this paper to give an accurate or comprehensive review of this fascinating subject. Some literature may be found, e.g., in [12].

In a series of papers [13–16], we introduced a theoretical framework for time-optimal quantum computing based on the action principle where the Hamiltonian is subject to a set of constraints (e.g., a finite energy, certain qubit interactions are forbidden), and we called it the quantum brachistochrone (QB). The QB was applied to quantum state evolution of pure [13] and mixed states [14] and to the optimal realization of unitary gates [15]. The predictions of the QB on the time complexity of generating unitaries with Hamiltonians which contains only one and two qubit interaction terms can be found in [16]. More recently, we discussed the problem of optimally generating entangling unitaries in a trilinear Ising chain subject to a coherent open loop control [12]. Assuming a fixed energy available and that local operations on qubits are time consuming, we found the laws of optimal control and the optimal minimal time for realizing a CNOT gate between indirectly coupled qubits. This time is shorter than previous results found in the literature so far [17]. The importance of the study of quantum gates in physical Hamiltonians with indirect couplings is that non-optimized procedures are usually time consuming and easily prone to decoherence effects and a degradation of the gate fidelity, both of which are critical for practical quantum computing. Interactions between indirectly coupled qubits via an intermediate qubit are also a typical scenario in a wide array of promising (scalable) experimental realizations of quantum information processing, e.g., in solid-state architectures [18], crystal lattice architectures [19], superconducting [20] and NMR technologies [21].

Here, we elaborate upon [12] on the problem of time-optimal generating unitary gates in linear spin chains. The motivation is essentially twofold. On the one hand, we introduce a general theoretical framework for finding the time-optimal way of generating a unitary gate in the more realistic situation where the target can be reached within a finite, tolerable error, in other words with a fidelity close to but smaller than 1. On the other hand, we extend our previous analysis of Ising models to the case when the interaction couplings between spins are not equal. Work related to our research can be found in [22–24], where analytical geometrical methods [25] and numerical algorithms [26] are used. We obtain new and interesting results for the minimal time duration of certain entangling gates and propose some experiments to test our theoretical formulae. The practical importance of such methods in time-optimal quantum control is also testified by recent experimental works on the quantum speed limit with a nearly perfect final fidelity, such as, e.g., that realized via a Bose–Einstein condensate in an optical lattice [9].

The rest of the paper is organized as follows. In section 2, we briefly review the main features of the QBT formalism for the time-optimal synthesis of unitary quantum gates with a given final fidelity. In section 3, we apply the formalism of the QBT and we introduce the main formulae for the problem of the efficient generation of the gate $U_{13}$, between the indirectly coupled boundary qubits 1 and 3 of a three-linear Ising chain subject to a local, time-consuming control on the intermediate qubit, when a finite energy is available. Section 4 is devoted to the discussion of the case of a final perfect matching between the time-optimal unitary evolution and the target, while section 5 analyzes the more general case when some errors are tolerated and the final fidelity is less than 1. We show that in general the minimal time required to reach the target is smaller than previous estimates given in the literature.

4 From the Greek ‘βραχιστος’, i.e. fast, and ‘χρονος’, i.e. time.
We also propose a series of possible experimental situations in which the results of the QBT formalism can be verified. Section 6 is used to discuss the time-optimal generation with fixed fidelity of the gate CNOT(1, 3), which can be achieved using a slightly modified interaction Hamiltonian plus the same local operation on qubit 2 and the same energy available. Finally, section 7 is devoted to the summary and discussion of our results. The derivation of the main formulae exposed in the main sections is outlined in appendices A–D.

2. The quantum brachistochrone with fixed fidelity

The goal is to minimize the time $T$ it takes to perform a unitary operation under the condition that the fidelity $f$ between the time optimal unitary at time $T$ and a certain target is fixed. In other words, we want to realize a certain target unitary $U_f$, but we tolerate that the target is reached only approximately, i.e. with a fidelity $f < 1$. We call this problem the quantum brachistochrone with fidelity (QBF). We also assume that the Hamiltonian $H$ is controllable and should obey some constraints, dictated either by theoretical conditions (e.g., only certain interactions among qubits are allowed) or by experimental requirements (e.g., a finite energy). The unitary operator $U(t)$ should then obey the Schrödinger equation. The QBF problem can be formulated in terms of the minimization of the following action:

$$S(U, H, U(T); \alpha, \Lambda, \lambda, \lambda_j) := \lambda \left[ |\langle U(T), U_f \rangle|^2 - (Nf)^2 \right] + \int_0^T ds [\alpha N + L_S + L_C],$$

(1)

$$L_S := \left\{ \Lambda, \frac{dU}{ds} U^\dagger - \alpha H \right\},$$

(2)

$$L_C := \alpha \sum_j \lambda_j f_j(H),$$

(3)

where $\langle A, B \rangle := \text{Tr}(A^\dagger B)$. The Hermitian operator $\Lambda(t)$ and the real functions $\lambda$ and $\lambda_j(t)$ are the Lagrange multipliers, while the Hamiltonian $H(t)$ and the evolution operator $U(t)$ are dynamical variables. The quantity log $N$ represents the number of qubits. Also, $U(T)$ is a dynamical variable, since the goal in the QBF problem is to obtain the time-optimal trajectories reaching the target $U_f$ only up to a fidelity $f$. The quantity $\alpha$ is the time cost. It plays the role of a ‘lapse’ function [14] connecting the physical time $t := \int \alpha(s) ds$ to the parameter time $s$.

The fidelity constraint is taken into account by the first term in the action $S$, and from variation with respect to $\lambda$, we obtain

$$|\langle U(T), U_f \rangle|^2 = (Nf)^2.$$  

(4)

Furthermore, variation of $L_S$ by $\Lambda$ gives the Schrödinger equation:

$$i \frac{dU}{dt} = HU, \quad \text{or} \quad U(t) = T e^{-i \int_0^t H \omega},$$

(5)

where $T$ is the time ordered product.

Variation of $L_C$ by $\lambda_j$ leads to the constraints for $H$:

$$f_j(H) = 0.$$  

(6)

In particular, the finite energy condition reads

$$f_0(H) := \frac{1}{2} [\text{Tr}(H^2) - N \omega^2] = 0,$$

(7)

where $\omega$ is a constant.

From the variation of $S$ with respect to $H$, we obtain

$$\Lambda = \lambda_0 H + \sum_{j \neq 0} \lambda_j \frac{\partial f_j(H)}{\partial H},$$

(8)
where we have used (7). From the variation of $S$ by $a$, upon using (6) and (8), we obtain the normalization condition

$$\text{Tr}(HA) = N,$$

while the variation of $S$ with respect to $U(T)$ gives the following final boundary conditions for $\Lambda$:

$$\Lambda(T) = -2\lambda \text{Im}[U(T), U_y U(T)^\dagger].$$

Finally, the variation of $S$ by $U$, use of equation (8) and a simple algebra give the QB equation

$$\frac{d\Lambda}{dr} = [H, \Lambda].$$

The QB together with the Schrödinger equation and the constraints define a two-boundary-value problem for the evolution of the unitary operator $U(t)$ and the Lagrange multiplier $\Lambda(t)$ with the initial $U(t = 0) = 1$ (where 1 is the identity matrix) and final conditions $\Lambda(t = T)$ (equation (10)), respectively. For a given target gate $U_f$ and fidelity $f$, the optimal Hamiltonian $H$ and the optimal time duration $T$ can be found in the following way: (a) solve the QB equation (11) backward in time subject to the constraints (6) and the final boundary condition (10) to obtain $H_{\text{opt}}(t)$, (b) integrate the Schrödinger equation (5) forward in time with the initial boundary condition $U(0) = 1$ to obtain $U_{\text{opt}}(t)$ and (c) determine the integration constants in $H_{\text{opt}}(t)$ by imposing the fidelity condition (4).

3. The QBF and an Ising Hamiltonian

We now explicitly solve the QBF problem for the physical system of three qubits (labeled by a superscript $a \in \{1, 2, 3\}$) arranged in a linear chain, interacting via an Ising Hamiltonian with the interaction couplings $J_{12}$ and $J_{23}$ and subject to a local and controllable magnetic field $B_i(t)$ ($i = x, y, z$) acting on the intermediate qubit. In more details, we work with the Ising Hamiltonian

$$H(t) := J_{12}\sigma_i^1\sigma_j^2 + J_{23}\sigma_i^2\sigma_j^3 + \vec{B}(t) \cdot \vec{\sigma},$$

where we have defined, e.g., $\sigma_i^j := \sigma_i \otimes \sigma_j \otimes 1$, $\sigma_i$ denotes Pauli operators and $N = 8$. We simplify the notation introducing the ratio $K := J_{23}/J_{12}$ and rescaling the time as $\tau := J_{12}t$, the energy as $\tilde{\omega} := \omega/J_{12}$ and the magnetic field as $\vec{B}(\tau) := B(t)/J_{12}$.

Our goal is to time-optimally generate the symmetric entangler gate $U_{13}^{\text{sym}}$, acting between the indirectly coupled qubits 1 and 3 (see equation (4) in [17]), i.e. the target is

$$U_f = U_{13}^{\text{sym}} := e^{-i\frac{\pi}{4}([\sigma_i^1 + \sigma_i^3]/2)}.$$

The form (12) of the physical Hamiltonian is guaranteed by the operator (8):

$$\Lambda(t) = \lambda_0 H + \sum_{i,j,k} \lambda_{ijk}(t) \sigma_i^1 \sigma_j^2 \sigma_k^3 + \sum_i [\eta_i \sigma_i^1 + \xi_i \sigma_i^3] + \sum_{i,j} [\mu_{ij} \sigma_i^1 \sigma_j^3 + v_{ij} \sigma_i^1 \sigma_j^3 + \rho_{ij} \sigma_i^2 \sigma_j^3].$$

where $\lambda_{ijk}(t)$, $\mu_{ij}(t)$, $v_{ij}(t)$, $\rho_{ij}(t)$, $\eta_i(t)$ and $\xi_i(t)$ are the Lagrange multipliers, and the indices $[i, j] \in \{x, y, z\}$. The finite energy condition (7) explicitly reads

$$\tilde{B}^2 = \omega_K^2 := \tilde{\omega}^2 - (1 + K^2) = \text{const},$$

and we must be sure that the available energy is enough so as to guarantee that $\omega_K^2 > 0$.

The relevant set of equations associated with the QB equation (11) with $H$ and $\Lambda$, respectively, given by (12) and (14) are presented as equations (A.1)–(A.5) in appendix A. In
this appendix, we also show that $\lambda_0$ and $v_\rho + K \rho_\rho$ are the integrals of the motion. Therefore, one can simplify the discussion by fixing the gauge freedom inherent to (1) and choosing $\lambda_0 = 1$. From this and the QB equation, it is then immediate to find that $\hat{B}_z = \text{const}$, and therefore, from the energy constraint (15) that $\hat{B}_0^2 + \hat{B}_y^2 := \hat{B}_0^2 = \text{const}$. Exploiting these integrals of the motion and after some lengthy but elementary algebra, we find that the general and non-trivial solution of the QB equation (11) is given by the Hamiltonian (12) with the time-optimal magnetic field

$$\vec{B}_{\text{opt}}(\tau) = \begin{pmatrix} \hat{B}_0 \cos \theta(\tau) \\ \hat{B}_0 \sin \theta(\tau) \end{pmatrix} \text{.}$$ (16)

precessing around the $z$-axis with the frequency $\hat{\Omega}$, where $\theta(\tau) := \hat{\Omega} \tau + \theta_0$ and $\hat{\Omega} := \Omega/J_{12}$ and $\theta_0$ are integration constants. For later use, it turns convenient to use the energy constraint (15) and to define (for $\phi \in [0, 2\pi]$)

$$\hat{B}_0 := \omega_K \cos \phi; \quad \hat{B}_z := \omega_K \sin \phi.$$ (17)

The next step is to integrate the Schrödinger equation (5) and to obtain the time-optimal evolution operator. The details of the calculation are shown in appendix B, and the result can be summarized as

$$U_{\text{opt}}(\tau) = [i^{13}(\tau) - i\hat{B}^{13}(\tau) \cdot \vec{\sigma}]^2,$$ (18)

where the operators $a^{13}(\tau)$ and $\hat{B}^{13}(\tau)$ act in the Hilbert space of qubits 1 and 3 and are defined in equation (B.19) of appendix B.

Finally, one has to impose the boundary conditions (10) on $\Lambda$ at the final time $\tau^* := J_{12}T$. Again, after some lengthy but simple algebra (for the explicit details the reader is referred to appendix C), it turns out that in the case of our 3-qubit model the relevant conditions can be summarized into the following equations:

$$\hat{\Omega} \tau_s = 2m\pi,$$ (19)

with $m$ being a non-zero integer$^5$ and

$$|M(\tau_s)| = 4f,$$ (20)

$$P(\tau_s) = R(\tau_s),$$ (21)

$$Q(\tau_s) = R^2(\tau_s).$$ (22)

where the functions $M(\tau_s), P(\tau_s), Q(\tau_s)$ and $R(\tau_s)$ are defined in equations (C.4)–(C.18) of appendix C. In other words, the QBF problem can be reduced to find the unknown integrals of the motion $\hat{B}_z, \hat{B}_0, \hat{\Omega}, \theta_0$ and $\tau^*$ from the constraints (19)–(22) (via equations (B.15) and (B.9), see appendix C).

4. Perfect matching: $f = 1$

We first consider the case of perfect matching between the time-optimal evolution operator $U_{\text{opt}}(\tau_s)$ and the target $U_f = U^{13}$. In other words, we assume that the fidelity is the maximum achievable, i.e. $f = 1$. In this case, it is immediate to see from equations (20), (B.14)–(B.9) and (C.4) that the only possibility is to have

$$\omega_i \tau_s = \pi n_i, \quad i = 1, 2, 3, 4,$$ (23)

$^5$ If $m = 0$, either $T = 0$ or $\Omega = 0$, which are both trivial cases.
where \( n_1, n_2, n_3, n_4 \) are the positive integers such that \( n_2 = n_1 + 2q - 1 \), \( n_1 = n_1 + 2s - 1 \) and \( n_4 = n_1 + 2r - 1 \), with \( q, r, s \) being the arbitrary integers. Then, from equations (23) and (B.14), we find that all \( s_j \) are zero, and from equations (C.9)–(C.18), we see that also \( P(\tau_0) = Q(\tau_0) = R(\tau_0) = 0 \), while \( M(\tau_0) = 4(-1)^n \). Therefore, equations (20)–(22) are automatically satisfied, and one is left with the conditions (19) and (23) to be satisfied via equations (B.15) and (B.9). This is essentially the same result which we had already found in our previous work [12] for the case of equal couplings \( K = 1 \) (see [12, equations (43) and (63)]). In particular, following exactly the same methods of [12], one first multiplies equation (B.15) by \( \tau_0 \), and then, using equation (23), inverts the former to find (with the help of (17)) the equivalent of equations (47)–(50) of [12]:

\[
\tau_0 = \pi \sqrt{\frac{f_{-}}{8K}}, \quad (24)
\]

\[
\hat{\Omega} = 2m \sqrt{\frac{8K}{f_{-}}}, \quad (25)
\]

\[
(\hat{B}_i)^2 = \frac{8K}{f_{-}} \left( m - \sqrt{\frac{g_{+}g_{-}}{8f_{-}}} \right)^2, \quad (26)
\]

\[
(\hat{B}_0)^2 = \frac{K}{f_{-}} \left[ 2\Delta f - \frac{(\Delta g)^2}{g_{+}g_{-} - \frac{g_{+}g_{-}}{f_{-}}} \right], \quad (27)
\]

where we have introduced

\[
f_{\pm} := (n_1^2 + n_2^2) \pm (n_3^2 + n_4^2), \quad (28)
\]

\[
g_{\pm} := (n_1^2 - n_2^2) \pm (n_3^2 - n_4^2) \quad (29)
\]

and their differences \( \Delta f := f_{+} - f_{-} \) and \( \Delta g := g_{+} - g_{-} \). Moreover, the energy and the Ising interaction couplings are subject to the constraint

\[
\omega_K^2 = \frac{2K}{f_{-}} \left[ f_{+} + 4m \left( m - \sqrt{\frac{g_{+}g_{-}}{2f_{-}}} \right) \right] - (1 + K^2), \quad (30)
\]

the values of Ising couplings are also constrained by the relation \( K = g_{-}/g_{+} \), and one has to guarantee that \( (\hat{B}_0)^2 \geq 0 \) and that \( \omega_K^2 > 0 \) for the existence of the solutions\(^7\).

Again, after a long but straightforward analysis (see [12]), one can show that the perfect \( (f = 1) \) time-optimal generation of the gate \( U_{13}^{(1)} \) is possible for the values of \( f_{-} = 3 \) and \( n_1 \) even, and the solution coincides with that given in equations (51)–(54) of [12] for the case of equal couplings. In particular, for \( n_1 = 2 \) and \( n_2 = n_3 = n_4 = 1 \), one obtains

\[
\tau_{\text{opt}} = \pi \sqrt{\frac{3}{\pi}}, \quad (31)
\]

\[
\hat{\Omega}_{\text{opt}} = 2m \sqrt{\frac{g}{3}}, \quad (32)
\]

\[
|\hat{B}_i|_{\text{opt}} = \sqrt{\frac{2}{3}} |m - 1|, \quad (33)
\]

\[
|\hat{B}_0|_{\text{opt}} = \sqrt{\frac{2}{3}}, \quad (34)
\]

\(^6\) In fact, when the couplings are equal, \( g_{+} = g_{-} \) and coincide with \( f_0 \) of equation (46) in [12]. Then, from (29) \( n_2 = n_3 \) so that also the \( f_0 \) coincide with equation (45) of [12].

\(^7\) This, in particular, requires that \( \text{sign}(f_{-}) = \text{sign}(K) = \text{sign}(g_{+}, g_{-}) \).
and
\[ \omega_1^2 = \frac{3}{4} [1 - \sqrt{\omega_2^2 + m^2}]. \]  
(35)

We stress that the duration time (31) is shorter than the numerical result proposed in the previous literature work [17] for the same trilinear Ising Hamiltonian and target as ours but for local controls which can selectivity and instantaneously address the single qubits of the chain. In other words, as already cautioned by their authors, the quantum control procedure discussed in [17] is not time optimal (although it performs better than other standard procedures).

For unequal couplings, i.e. \( K \neq 1 \), we could not find solutions of the equations (24)–(30) which satisfy the conditions \( (\hat{B}_0)^2 \geq 0, \omega_k^2 > 0 \) and \( K = g_-/g_+ \) for \( f_- \) smaller than 7. The reason of this unexpected result for the \( K \neq 1 \) case can be found by taking into consideration the more general ansatz of almost perfect matching between \( U_{\text{opt}}(\tau_\ast) \) and the target \( U_{f_-} \), i.e. the ansatz of a fidelity \( f < 1 \). This is the topic of the next section.

5. Almost perfect matching: \( f \approx 1 \)

We are now interested in finding the solution to the QBF problem in the case when the required final fidelity is not exactly 1, but we allow for some error. In other words, we want to achieve a final fidelity
\[ f = 1 - \frac{\epsilon^2}{8}, \]  
(36)

where \( |\epsilon| \ll 1 \). By looking at the final boundary condition (20) and taking into account (36), it is immediate to verify that the QBF problem can be solved by generalizing the ansatz (23) to
\[ \omega_i \tau_\ast = \pi n_i + \sigma_i, \quad i = 1, 2, 3, 4, \]  
(37)

where the real variables \( \sigma_i \ll 1 \), while the integers \( n_i \) satisfy the same relations as those written below equation (23).

Then, substituting (37) into equations (20)–(22), we obtain the following constraints for the \( \sigma_i \):
\[ \left[ b_1 - b_4 \right] \frac{b_1 \sigma_1 - b_4 \sigma_4}{n_1} = \left[ b_2 - b_3 \right] \frac{b_2 \sigma_2 - b_3 \sigma_3}{n_2}, \]  
(38)
and
\[ (b_1 - \sin \phi) \frac{\sigma_1}{n_1} + (b_2 - \sin \phi) \frac{\sigma_2}{n_2} - (b_3 - \sin \phi) \frac{\sigma_3}{n_3} = (b_4 - \sin \phi) \frac{\sigma_4}{n_4} \]  
(39)

and
\[ \sigma_1^2 + \sigma_2^2 + \sigma_3^2 + \sigma_4^2 = \epsilon^2. \]  
(40)

In principle, the procedure is now similar to that of the previous section. In other words, one should invert equation (B.15) in order to express the unknown constants of the motion \( \hat{B}_0, \hat{B}_z, \hat{\Omega} \) and \( \tau_\ast \) in terms of the integers \( n_i \) and the variables \( \sigma_i \), and then determine the former (constants) by minimizing \( \tau_\ast \) over the latter (integers). However, as shown in appendix D, only for values of the coupling ratio \( |K| \) close to 1, is it possible to find time-optimal solutions. For pedagogical purposes, without losing generality, we present the prototypical ansatz of positive \( K \), i.e. \( K = 1 + \delta K \), with \( |\delta K| \ll 1 \). The case of negative \( K \) can be dealt with along similar lines.\(^8\)

\(^8\) In this case, for the reality of the duration time, i.e. equation (31), one has to work with \( f_- \) negative.

7
Then, performing a perturbative expansion in $\delta K$, after some simple and tedious algebra (see appendix D) we obtain a self-consistent set of values for the variables $\sigma_i$ (equations (D.16)–(D.17) of appendix D), which, for a given $K$ close to 1, leads to the following time-optimal constants of the unitary evolution:

$$
\tau_{\text{opt}} \simeq \pi \sqrt{\frac{3}{8} \left(1 - \frac{\delta_{sK}}{2}\right)},
$$

(41)

$$
\hat{\Omega}_{\text{opt}} \simeq 2 \sqrt{\frac{8}{3} \left(1 + \frac{\delta_{sK}}{2}\right)},
$$

(42)

$$
\hat{B}_{z,\text{opt}} \simeq \left(1 + \frac{8}{\sqrt{3}}\right) \left[1 + \frac{(\sqrt{2} + \sqrt{3})}{(2\sqrt{2} + \sqrt{3})} \delta_{sK}\right],
$$

(43)

$$
|\hat{B}_0|_{\text{opt}} \simeq \sqrt{\frac{3}{8}} \left[1 + \frac{1}{5} \left[\delta K + \frac{2(12\sqrt{6} + 31)}{\pi} \sqrt{\frac{\Delta_{sK}}{27 + 4\sqrt{6}}}\right]\right],
$$

(44)

where we have defined

$$
\Delta_{sK} := \epsilon^2 - \frac{9\pi^2}{32} (\delta K)^2,
$$

(45)

$$
\delta_{sK} := \delta K - \frac{2(1 + 2\sqrt{6})}{3\pi} \sqrt{\frac{\Delta_{sK}}{27 + 4\sqrt{6}}}.
$$

(46)

We point out that the optimal time duration (41) is approximately a function of $K^{-1/2}$, i.e. it decreases for increasing $K$. The optimal values of the integers are again $n_1 = 2$, $n_2 = n_3 = n_4 = 1$, for which $f_- = 3$, and in this case, the integer $m$ can also be optimized (see appendix D) as $m = 1$. From the above equations, it is also clear that, in order for the time-optimal evolution to exist, i.e. for the values of $\tau_{\text{opt}}, \hat{B}_{z,\text{opt}}, \hat{B}_0$ and $\hat{\Omega}$ to be real, the ratio of the couplings in the Ising Hamiltonian must satisfy the condition $\Delta_{sK} \geq 0$ or, in terms of the fidelity, using (36)

$$
|\delta K| \leq \frac{16}{3\pi} \sqrt{1 - f}.
$$

(47)

This means that the better we want to approximate the unitary target, i.e. the closer the fidelity should be to 1, the smaller the deviation from one of the ratios between the Ising couplings that we can choose so that the perturbative expansion and the time-optimal evolution laws are self-consistent. Alternatively, if we have an experiment where $K$ is given, we can read formula (D.18) as predicting that the distance of $K$ from the unit value determines the maximal fidelity that we can hope to achieve (and impose in the QBF formalism). Furthermore, we have to choose an energy which satisfies the following constraint:

$$
\hat{\omega}_K^2 \simeq \frac{16}{3} \left(1 + \frac{3}{8}\right) \left[1 + \frac{(4\sqrt{2} + 3\sqrt{3})}{2(2\sqrt{2} + \sqrt{3})} \left[\delta K + \frac{(\sqrt{6} + 29)}{15\pi} \sqrt{\frac{\Delta_{sK}}{27 + 4\sqrt{6}}}\right]\right].
$$

(48)

We give a few examples of concrete situations where our formalism can operate and give the shortest time duration of the quantum control in order to achieve the gate $U_{13}^{15}$ with fixed energy and fidelity. For instance, in the context of NMR [28], we can think of an experiment where the Ising chain is the H–N–H part of the molecule of ethanamide [24], for which the Ising couplings are $J_{12} = J_{23} \simeq 88.05$ Hz, or the F–F–F part of the trifluoroaniline molecule [29], for which the Ising couplings are $J_{12} = J_{23} \simeq 20$ Hz. For these molecules, $K = 1$
and the time optimal duration is given by equation (31) in the previous section. On the other hand, we can imagine an NMR experiment based on the H–H–H chain in the molecule of the 1-chloro-2-nitro-benzene [30], where the Ising couplings are $J_{12} \simeq 8$ Hz and $J_{23} \simeq 7$ Hz, or an experiment based on the H–H–P chain in the molecule of 2-chloroethenylphosphonic acid [31], with $J_{12} \simeq 9.1$ Hz and $J_{23} \simeq 11.3$ Hz. The former has a ratio $K \simeq 0.875$, and the optimal fidelity reachable according to (D.18) is $f_{\text{max}} \simeq 0.995$, within a optimal time duration given by equation (41). The latter has a ratio $K \simeq 0.805$, and the optimal fidelity reachable according to (D.18) is $f_{\text{max}} \simeq 0.987$. We note that even taking the popular NMR model of the C–C–C chain, i.e. the alanine molecule [32], with $J_{12} \simeq 54$ Hz, $J_{23} \simeq 35$ Hz and a relatively large $\delta K \simeq 0.35$, the maximal achievable fidelity is still $f_{\text{max}} \simeq 0.957$. It would also be interesting to apply the QBT formalism to experiments involving, e.g., superconducting qubits.

6. Changing coordinates: CNOT(1, 3)

An analysis similar to that performed in the last section can be made in the following two situations. On the one hand, the physical Hamiltonian (12) may be available in an experiment performed within the standard computational basis (the Hilbert space spanned by the states $\{|0\rangle, |1\rangle\} \otimes \{|0\rangle, |1\rangle\} \otimes \{|0\rangle, |1\rangle\}$, but from the point of view of another laboratory the Hilbert space is seen as being spanned by the states $\{|0\rangle, |1\rangle\} \otimes \{|0\rangle, |1\rangle\} \otimes \{|+, |-\rangle\}$, where the basis for qubit 3 is $\{|+, |-\rangle\}$ (with $|+\rangle := W|0\rangle = (|0\rangle + |1\rangle)/\sqrt{2}$, $|-\rangle := W|1\rangle = (|0\rangle - |1\rangle)/\sqrt{2}$ (W is the Walsh–Hadamard transform). Thus, the second laboratory observes an effective, rotated Hamiltonian given by

$$H'(\tau) = \sigma_x^1 \sigma_x^2 + K \sigma_z^1 \sigma_z^3 + \vec{B}(\tau) \cdot \vec{\sigma}^2.$$  \hfill (49)

Alternatively, one may simply assume that the Hamiltonian (49) is available in an experiment performed within the standard computational basis for all the qubits. The Hamiltonians (12) and (49) are related by

$$H'(\tau) = V^3 H(\tau) V^3,$$  \hfill (50)

where $V^3 := 1 \otimes 1 \otimes W$. Now, the goal is to time-optimally synthesize with fixed fidelity the gate CNOT(1, 3):

$$U_f := \text{CNOT}(1, 3) = e^{-i\tau \frac{\pi}{4}(1+\sigma_z^3-\sigma_1^3-\sigma_2^3)}.$$  \hfill (51)

As explained in our previous work [12], an analysis parallel to that of the previous sections can be made. The relevant QB equations are still given by (A.1)–(A.5), with the only replacement $\rho_{\text{H}} \rightarrow \rho_{\text{A}}$. Then, the time-optimal evolution operator becomes

$$U_{\text{opt}}(\tau) = V^3 U_{\text{opt}}(\tau) V^3,$$  \hfill (52)

where $U_{\text{opt}}(\tau)$ is given by (18).

Also, the new target CNOT(1, 3) can be diagonalized in the (1, 3 qubit subspace) as

$$U_f = V^3 U_{\text{opt}}^{13} V^3 = V^3 \text{Diag}(1, 1, 1, -1) V^3,$$  \hfill (53)

where the operator $U_{\text{opt}}^{13}$ acts in the 1,3 qubit subspace. Then, following the same methods of the previous section, it is easy to show that the only relevant changes are in flip of the signs in front of the terms $x_1$ and $x_3$ in equations (C.4), (C.9) and (C.18). Furthermore, in formula (B.15), we have choose the new positive integers $n'_i$, $i = 1, 2, 3, 4$, with $n'_1 = n'_2 + 2q'$, $n'_3 = n'_4 + 2\nu'$ and $n'_3 = n'_4 + 2r' + 1$, where $q'$, $\nu'$ and $r'$ are arbitrary integers. Considerations similar to those made in the previous section finally lead to expressions (24)–(27) and to the minimization of the evolution time $\tau_e$ for $f_\text{=} = 3$ and $n_1$ odd. In particular, for $n_1 = n_2 = n_3 = 1$ and $n_4 = 2$, the solution to the QBF problem with perfect matching ($f = 1$) between $U_{\text{opt}}(\tau_e)$ and
the CNOT\((1, 3)\) target is given again, for equal couplings \(K = 1\), by equations (31)–(35) (cf equations (51)–(55) of [12]). For different couplings, the perturbative expansion in \(\delta K\) leads instead to the time-optimal solution (41)–(48), except for a global change of sign for \(\Omega\) and \(B_z\) (see appendix D).

7. Discussion

We have presented the general theoretical framework for determining the time-optimal way of generating a target unitary quantum gate when the physical Hamiltonian is subject to certain constraints (at least a fixed energy available) and when some errors on the target are tolerated, i.e. the fidelity is assumed to be fixed and smaller than 1. We have then applied the formalism, which for brevity we called QBT, to the model study of a trilinear Ising chain with unequal Ising interaction couplings and where the intermediate qubit is subject to coherent control via a local, but in principle time-consuming, magnetic field. For the case of a fixed fidelity equal to 1 (i.e. a perfect matching with the target), we explicitly gave analytical formulae of the time-optimal control laws and of the minimal time required to realize the entangling gate \(U_{13}^s\) between the indirectly coupled qubits of the chain when the Ising couplings are equal. The analytical expression for the minimal time found is shorter than the numerical expression found (using standard geometrical quantum control methods for the same trilinear Ising Hamiltonian plus instantaneous individual control of the qubits) in [17]. For the case of a fixed fidelity smaller than 1, we performed an perturbative expansion around a ratio between the Ising couplings equal to 1, and we gave analytical results for the time-optimal control laws and for the minimal time required to achieve \(U_{13}^s\) for unequal couplings. Changing the computational basis for one of the qubits at the end of the chain, similar methods can be used to analytically express the time-optimal control laws for generating the CNOT gate between the indirectly coupled qubits. All of the above results are new and analytical and constitute an improvement with respect to the present literature for the values of the minimal time required to generate certain unitary quantum gates between indirectly coupled qubits. We also proposed a series of experiments within the NMR paradigm to test our theoretical predictions. The main advantage inherent to the use of the QBF formalism appears to lie in the fact that (at least for these simple low-dimensional models) it naturally allows for local quantum operations which in principle may have a non-zero time cost, while the standard geometrical methods usually assume that local operations should instantaneously be performed. In some sense, our ansatz is slightly more restricted than that of [17], since we also impose the finite energy condition equation (7). This, in turn, determines the appearance of constraint (35) (or (48)), which relates the allowed values of the Ising couplings to the energy available in the experiment. As we already pointed out in [12], we conjecture that this feature is the consequence of working with equality constraints on the Hamiltonian in the action principle, and we expect that it should be mitigated when such an assumption is relaxed and one also considers inequality constraints (for example, an energy available bounded from above). We conjecture that also the difficulty in finding explicit results in the case of arbitrary \(K\) far from 1 stems from the same technical point. We plan to extend our methods to the study of chains with more qubits and more complex topologies, to extend the allowed local controls to all qubits and to consider other quantum gates. Also, some work is in progress related to the speed of quantum information transmission (e.g. transfer of coherence) along spin chains and to the role of entanglement during the QBF evolution. It will be interesting, e.g., to compare these analytical results with previous numerical works (based on the efficient Krotov algorithm) on the optimal control of spin chains with a finite or infinite length (see, e.g., [7, 8]) and their relation to the maximum achievable quantum speed limit [5, 6]. This study may prove to be pivotal in the design of actual
quantum computer architectures where accurate and fast transmission of quantum information between distant qubits is required.

Appendix A. QB and integrals of motion

Comparing the coefficients of the generators of $su(8)$ on both sides of (11), with $\Lambda$ given by (14) and $H$ given by (12), we find that the relevant QB equations are

\[ (\hat{\lambda}_0 \hat{B}_x) \cdot = -2(v_{yz} + K\rho_{yz}), \]
\[ (\hat{\lambda}_0 \hat{B}_y) \cdot = 2(v_{zx} + K\rho_{zx}), \]
\[ (\hat{\lambda}_0 \hat{B}_z) \cdot = 0, \]
\[ \dot{v}_{zz} = 2(B_x v_{zy} - B_y v_{zx}), \]
\[ \dot{\rho}_{zz} = 2(B_x \rho_{yz} - B_y \rho_{xz}), \]

where $\hat{\lambda}_0 := J_{12} \lambda_0$ is a rescaled Lagrange multiplier. First of all, using the energy constraint (7), we note that $(\hat{B})^2 = \hat{B}_x^2 + \hat{B}_y^2 + \hat{B}_z^2 = \text{const.}$ Moreover, from (8), and the QB equations (11) and (14), we can compute $0 = \text{Tr}[\hat{A}H] = 8[\hat{\omega}^2 \hat{\lambda}_0 + (\hat{v}_{zz} + K\hat{\rho}_{zz})]$. Then, taking the time derivative of $(\hat{B})^2$, using equations (A.1)–(A.5) and the latter result, a simple algebra shows that $\hat{\lambda}_0 = d_1$ and $v_{zz} + K\rho_{zz} = d_2$, where $d_1$ and $d_2$ are constants. Finally, imposing the normalization condition (9), one finds that $d_1 \hat{\omega}^2 + d_2 = 1$.

Appendix B. Time-optimal evolution operator

We now proceed to integrate the Schrödinger equation (5) for $U_{opt}(\tau)$, given that $H_{opt}(\tau)$ is expressed via equations (12) and (16). For this purpose, we exploit the following well-known rotation formula for the Pauli matrices:

\[ e^{-i \frac{\theta(\tau)}{2} \sigma_z} e^{i \frac{\theta(\tau)}{2} \sigma_x} = \cos \theta(\tau) \sigma_x + \sin \theta(\tau) \sigma_z, \]

and we rewrite the time-optimal Hamiltonian as

\[ H_{opt}(\tau) = e^{-i \frac{\theta(\tau)}{2} \sigma_z} H_0 e^{i \frac{\theta(\tau)}{2} \sigma_z}, \]

where we have introduced the constant operator

\[ H_0 := \hat{B}_0 \sigma_x^2 + (\sigma_x^3 + K\sigma_z + \hat{B}_0) \sigma_z^2. \]

Furthermore, defining the transformed unitary operator

\[ \tilde{U}(\tau) := e^{i \frac{\theta(\tau)}{2} \sigma_z} U(\tau), \]

we easily check that since $\tilde{U}(\tau)$ should obey the Schrödinger equation (5), $\tilde{U}(\tau)$ should also satisfy

\[ i \frac{d\tilde{U}}{d\tau} = \tilde{H} \tilde{U}, \]
with the time-independent Hamiltonian
\[
\hat{H} := H_0 - \frac{\hat{\Omega}}{2} \sigma_z^2 = \text{const.}
\] (B.6)

We note that the constant Hamiltonian \( \hat{H} \) is diagonal in the 1,3 qubit subspace:
\[
\hat{H} = \hat{B}_0 \sigma_z^2 + B_{13}^D \sigma_x^2
\] (B.7)
where we have introduced the operator \( B_{13}^D \) acting in the 1,3 qubit subspace:
\[
B_{13}^D := \omega_K \text{Diag}[b_1, b_2, b_3, b_4],
\] (B.8)
which depends upon the constants
\[
b_i := \sin \phi + \frac{1}{\omega_K} \left[ (\delta_{i1} - \delta_{i4})(1 + K) + (\delta_{i2} - \delta_{i3})(1 - K) - \frac{\hat{\Omega}}{2} \right],
\] (B.9)
where \( i = 1, 2, 3, 4 \) and \( \delta_{ij} \) is the Kronecker symbol.

Then, solving equation (B.5) together with equation (B.7) for \( \hat{U}(\tau) \) and finally inverting (B.4), it is easy to check that the time-optimal unitary operator \( U_{\text{opt}}(\tau) \) evolves as
\[
U_{\text{opt}}(\tau) = e^{-i\hat{\theta}(\tau) \sigma_z^2} e^{-i\hat{\theta}_0 \sigma_z^2}.
\] (B.10)

In particular, the exponential of the constant Hamiltonian appearing on the right-hand side of equation (B.10) is also diagonal (in the 1, 3 qubit subspace) and can be expanded as
\[
e^{-i\hat{\theta} \tau} = C_{13}^D(\tau) - iS_{13}^D(\tau) \hat{H},
\] (B.11)
where we have introduced the diagonal operators
\[
S_{13}^D(\tau) := \text{Diag}[s_1(\tau), s_2(\tau), s_3(\tau), s_4(\tau)],
\] (B.12)
\[
C_{13}^D(\tau) := \text{Diag}[c_1(\tau), c_2(\tau), c_3(\tau), c_4(\tau)],
\] (B.13)
which depend upon the functions of \( \tau \):
\[
s_i(\tau) := \frac{\sin(\omega_i \tau)}{\omega_i}, \quad c_i(\tau) := \cos(\omega_i \tau),
\] (B.14)
and the constants
\[
\omega_i := \omega_K \sqrt{\cos^2 \phi + b_i^2}.
\] (B.15)

Thus, inserting equation (B.11) into equation (B.10), one obtains the more explicit expression (18) for the time-optimal evolution of the unitary operator, where we have defined
\[
a_{13}^D(\tau) = \cos \left[ \frac{\hat{\Omega} \tau}{2} \right] C_{13}^D(\tau) - \sin \left[ \frac{\hat{\Omega} \tau}{2} \right] B_{13}^D S_{13}^D(\tau),
\] (B.16)
\[
b_{13}^D(\tau) = B_0 S_{13}^D(\tau) \cos \left[ \frac{\hat{\Omega} \tau}{2} + \theta_0 \right],
\] (B.17)
\[
b_{13}^D(\tau) = B_0 S_{13}^D(\tau) \sin \left[ \frac{\hat{\Omega} \tau}{2} + \theta_0 \right],
\] (B.18)
\[
b_{13}^D(\tau) = \sin \left[ \frac{\hat{\Omega} \tau}{2} \right] C_{13}^D(\tau) + \cos \left[ \frac{\hat{\Omega} \tau}{2} \right] B_{13}^D S_{13}^D(\tau).
\] (B.19)

Expression (18) still depends upon the integration constants \( \hat{B}_0, \hat{B}_z, \hat{\Omega} \) and \( \theta_0 \) and the optimal duration time \( \tau_0 \) of the unitary evolution. These parameters are determined by imposing the final fidelity constraint (4) and the final boundary condition (10).
Appendix C. Final boundary conditions on \( \Lambda \)

The boundary conditions for \( /\Lambda_1 \) at the final time \( \tau^* := J_{12}T \) in our 3-qubit model explicitly read

\[
\Lambda(\tau^*) = 2\lambda U_{13}^j \bar{B}^j(\tau^*) \cdot \sigma^2 \text{Tr}[U_{\text{opt}}(\tau^*)U_f^\dagger].
\]  

(C.1)

Let us now compute these conditions. First, we note that our final target (13) is diagonal in the 1, 3 qubit subspace and can be written as

\[
U_f = e^{i\hat{\Omega}_1 T} U_{13}^j, \quad U_{13}^j := \text{Diag}(-1, 1, 1, 1).
\]  

(C.2)

Then, using (18) and (C.2), we can write

\[
\text{Tr}[U_{\text{opt}}(\tau^*)U_f] = 2 \left( \cos \left( \frac{\hat{\Omega}_{\tau^*}}{2} \right) M - \sin \left( \frac{\hat{\Omega}_{\tau^*}}{2} \right) N \right),
\]  

(C.3)

where we have defined

\[
M(\tau^*) := \text{Tr} \left[ C_{13}^j U_{13}^j \right] = c_1 + c_2 + c_3 - c_4,
\]  

(C.4)

\[
N(\tau^*) := \text{Tr} \left[ B_{13}^j S_{13}^j U_{13}^j \right] = b_1 s_1 + b_2 s_2 + b_3 s_3 - b_4 s_4.
\]  

(C.5)

Now, inserting (C.3) into (C.1), from the \( \sigma_2^x, \sigma_2^y, \sigma_2^z \) terms of \( /\Lambda_1(\tau^*) \), we obtain the final boundary conditions

\[
\cos \theta(\tau^*) = \frac{\lambda P(\tau^*)}{2\omega_K} \cos \left( \frac{\hat{\Omega}_{\tau^*}}{2} + \theta_0 \right) \text{Tr}[U_{\text{opt}}(\tau^*)U_f^\dagger],
\]  

(C.6)

\[
\sin \theta(\tau^*) = \frac{\lambda P(\tau^*)}{2\omega_K} \sin \left( \frac{\hat{\Omega}_{\tau^*}}{2} + \theta_0 \right) \text{Tr}[U_{\text{opt}}(\tau^*)U_f^\dagger],
\]  

(C.7)

\[
\hat{B}_z = \frac{\lambda}{2} \left( \cos \left( \frac{\hat{\Omega}_{\tau^*}}{2} \right) N + \sin \left( \frac{\hat{\Omega}_{\tau^*}}{2} \right) M \right) \cdot \text{Tr}[U_{\text{opt}}(\tau^*)U_f],
\]  

(C.8)

where

\[
P(\tau^*) := \text{Tr} \left[ S_{13}^j U_{13}^j \right] = s_1 + s_2 + s_3 - s_4.
\]  

(C.9)

Upon using (C.3) into (C.6) and (C.7), we find that these can be nontrivially\(^9\) satisfied only if

\[
\tan \theta(\tau^*) = \tan \left( \frac{\theta(\tau^*) + \theta_0}{2} \right),
\]  

(C.10)

whose solution is given by

\[
\hat{\Omega}_{\tau^*} = 2m\pi,
\]  

(C.11)

where \( m \) is a non-zero integer\(^{10}\). Using the latter formula, we can compactly rewrite equations (C.6)–(C.8) as

\[
\lambda M(\tau^*) P(\tau^*) = \omega_K,
\]  

(C.12)

\[
\lambda M(\tau^*) N(\tau^*) = \hat{B}_z.
\]  

(C.13)

Moreover, from the fidelity equation (4) and the definition

\[
\text{Tr}[U_{\text{opt}}(\tau^*)U_f^\dagger] := | \text{Tr}[U_{\text{opt}}(\tau^*)U_f^\dagger] | e^{-i\chi} = 8 f e^{-i\chi},
\]  

(C.14)

\(^9\) The trivial solutions are \( \hat{B}_0 \) or \( \hat{B}_z \), and equal to zero.

\(^{10}\) If \( m = 0 \), either \( T = 0 \) or \( \Omega = 0 \), which are both trivial cases.
and from (C.3) and (C.14), we obtain
\[ e^{i\lambda} = (-1)^n \text{sign}[M(\tau_\ast)] \]  
(C.15)

and equation (20).

Let us now impose the normalization condition (9) at the final time \( \tau_\ast \). Multiplying (10) by \( H(\tau_\ast) \) and using (9), we can express the Lagrange multiplier \( \lambda \) as
\[ \lambda = -2 \text{Im}(e^{i\lambda} \text{Tr}[U_{\text{opt}}(\tau_\ast)U_j^\dagger H_{\text{opt}}(\tau_\ast)])^{-1}. \]  
(C.16)

After some lengthy but simple algebra, from (13), (16), (18) and (C.11), one can compute
\[ \text{Tr}[U_{\text{opt}}(\tau_\ast)U_j^\dagger H_{\text{opt}}(\tau_\ast)] = 2i(-1)^{m+1} \omega_R R(\tau_\ast), \]  
(C.17)

where we have defined
\[
R(\tau_\ast) := \left[ \cos^2 \phi + \frac{b_1}{2} (b_1 - b_2 + 2 \sin \phi) \right] s_1 + \left[ \cos^2 \phi + \frac{b_2}{2} (b_2 - b_3 + 2 \sin \phi) \right] s_2
+ \left[ \cos^2 \phi - \frac{b_1}{2} (b_2 - b_3 - 2 \sin \phi) \right] s_3 - \left[ \cos^2 \phi - \frac{b_2}{2} (b_1 - b_4 - 2 \sin \phi) \right] s_4.
\]  
(C.18)

Finally, substituting (C.15) and (C.17) into (C.16), we obtain
\[ \lambda = \frac{\text{sign}[M(\tau_\ast)]}{4 f \omega_R R(\tau_\ast)}. \]  
(C.19)

Thus, if we can determine the values of \( M(\tau_\ast) \) and \( R(\tau_\ast) \), from the latter equation we have determined the optimal value of the Lagrange multiplier \( \lambda \) for a given fidelity. Furthermore, using (C.19), the multiplier \( \lambda \) can be eliminated from (C.12)–(C.13), which, after some simple manipulations, become equations (21)–(22), where
\[ Q(\tau_\ast) := \omega_K [(1 + K)(s_1 + s_4) + (1 - K)(s_2 - s_3)]. \]  
(C.20)

**Appendix D. Perturbative expansion around \( K = 1 \)**

We first compute the function \( f_- \) for the case when the target is the entangler gate \( U_j^{1\dagger} \), i.e. when the integers are \( n_1, n_2 = n_1 + 2q - 1, n_3 = n_1 + 2s - 1 \) and \( n_4 = n_1 + 2r - 1 \). From its definition, equation (29), we obtain
\[ f_- = \ln\left[ 2(r - q - s) + 1 \right] + 4\ln(r - 1) - q(q - 1) - s(s - 1) - 1. \]  
(D.1)

Now let us assume that the Ising couplings are not equal, i.e. \( |K| \neq 1 \), and let us compute \( \omega_{01} \tau_\ast \), \( \omega_{02} \tau_\ast \), \( \omega_{03} \tau_\ast \) and \( \omega_{04} \tau_\ast \). From definitions (B.9) and (B.15) and equations (19) and (37), we obtain
\[
\omega_{01} \tau_\ast \omega_{01} \tau_\ast + \omega_{02} \omega_{01} \tau_\ast + \omega_{03} \omega_{01} \tau_\ast + \omega_{04} \omega_{01} \tau_\ast = (\pi n_1 + \sigma_1)^2,
\]  
(D.2)

\[
\omega_{02} \omega_{01} \tau_\ast + \omega_{03} \omega_{01} \tau_\ast + \omega_{04} \omega_{01} \tau_\ast = (\pi n_2 + \sigma_2)^2,
\]  
(D.3)

\[
\omega_{03} \omega_{01} \tau_\ast + \omega_{04} \omega_{01} \tau_\ast = (\pi n_3 + \sigma_3)^2,
\]  
(D.4)

\[
\omega_{04} \tau_\ast + \omega_{02} \omega_{01} \tau_\ast + \omega_{03} \omega_{01} \tau_\ast + \omega_{04} \omega_{01} \tau_\ast = (\pi n_4 + \sigma_4)^2.
\]  
(D.5)

Then, summing (D.2)–(D.5) and subtracting from this (D.3) and (D.4), we obtain the duration time of the unitary evolution:
\[ \tau_\ast \simeq \pi \sqrt{\frac{f_-}{8K}} \left[ 1 + \frac{2f_-}{\pi f_-} \right]. \]  
(D.6)
where we have introduced (for notational consistency with (29)) \( f_+^n := (n_1 \sigma_1 + n_2 \sigma_2) \pm (n_2 \sigma_3 + n_1 \sigma_1) \), and we discarded contributions of \( O(\sigma^2) \). Subtracting (D.4) from (D.3), we obtain the constant component \( \hat{B}_0 \) of the magnetic field:

\[
\omega \sin \phi = \frac{1}{\hat{\tau}_*} \left[ \frac{\pi^2 \Delta g}{8 (1 - K) \tau_*} \left[ 1 + \frac{2 \Delta g \sigma^2}{\pi \Delta g} \right] + m \pi \right], \tag{D.7}
\]

where \( g_+^n := (n_1 \sigma_1 - n_2 \sigma_2) \pm (n_3 \sigma_3 - n_2 \sigma_3) \), \( \Delta g_+^n := g_+^n - g_+^n \) (contributions of \( O(\sigma^2) \) discarded). From the sum of (D.2), (D.3), (D.4) and (D.5), we obtain instead a constraint on \( \omega^2 \) (and therefore, via (15), on \( \omega \hat{B}_0 \)):

\[
\omega^2 \simeq \frac{\pi^2}{4 \hat{\tau}_*^2} \left[ f_+ + 4m^2 + \frac{m \pi \Delta g}{2 \tau_*} + \frac{2 f^2}{\pi} \right]. \tag{D.8}
\]

Finally, from the sum of (D.2) and (D.4), to which we subtract (D.3) and (D.5), we obtain the constraint

\[
(1 - K)(g_+ + g_-) - (1 + K) \Delta g = \frac{2}{\pi} (1 + K) \Delta g - (1 - K)(g_+^n + g_-^n) \] \tag{D.9}

(modulo \( O(\sigma^2) \) contributions). The last equation explains the origin of the unexpected result of section 4. In fact, for \( |K| \neq 1 \), the only way for which equation (D.9) can hold to zero order in \( \sigma \) is that the constraint \( K = g_- / g_+ \) must hold. When one is looking for the minimum (odd integer) value of the function \( f_- \) (i.e. from (D.6) the minimum time duration \( \tau_* \) of the unitary evolution) this constraint together with those coming from \( (\hat{B}_0) \) > 0 and \( \omega \hat{B}_0 > 0 \) (see the discussion below equations (24)–(30)) must be simultaneously satisfied by the integer numbers \( n_1, q, r \) and \( s \). This is a very strong set of constraints. No surprise that, at least for \( f_- \) up to 7 (we did not try higher, unrealistic values of \( f_- \) and, therefore, of \( \tau_* \)), only the choice of \( n_2 = n_1 \) is allowed, thus enforcing \( g_+ = g_- \) and \( K = 1 \). The only possible way out of this ‘impasse’ is to assume that we can work with \( |K| \) close to 1 and hope that the right-hand side and the left-hand side of equation (D.9) are of the same order.

Let us then assume, e.g., that \( K = 1 + \delta K \), where we take \( |\delta K| \ll 1 \). First of all, performing an expansion in \( \delta K \) of the condition (D.9), we indeed find that this separates into two conditions, coming from the zero-order and the first-order terms in \( \delta K \) and \( \sigma_1 \), respectively:

\[
n_2 = n_1, \tag{D.10}
\]

\[
n_2 (\sigma_2 - \sigma_3) = -\frac{\pi}{4} (n_1^2 - n_2^2) \delta K. \tag{D.11}
\]

That is to say, \( \delta K \) must be of the order of \( \sigma_1 \), i.e. from (40), we must have \( \delta K \lesssim \epsilon \).

Then, we perform a perturbative expansion in \( \delta K \) of the conditions on the variables \( \sigma_1 \), i.e. an expansion of equations (38)–(39). Exploiting (B.9), we obtain, up to the lowest order in both \( \delta K \) and \( \sigma_1 \), the following:

\[
\left[ \omega \sin \phi - \frac{\hat{\Omega}}{2} + 2 \right] \frac{\sigma_1}{n_1} = \left[ \omega \sin \phi - \frac{\hat{\Omega}}{2} - 2 \right] \frac{\sigma_4}{n_4} \tag{D.12}
\]

\[
\left( \frac{\sigma_1}{n_1} - \frac{\sigma_4}{n_4} \right) = \frac{\hat{\Omega}}{4} \left( \frac{\sigma_1}{n_1} + \frac{\sigma_2}{n_2} + \frac{\sigma_3}{n_3} + \frac{\sigma_4}{n_4} \right). \tag{D.13}
\]

We can now solve equations (D.12)–(D.13) together with (40). Using the lowest order approximations to the time-optimal evolution (equations (31)–(33), or equations (D.6)–(D.7),
with \( n_1 = 2, n_2 = n_3 = n_4 = 1 \) and \( f_- = 3 \), we can find that \( \omega_K \sin \phi - \dot{\Omega}/2 \simeq -1 \). Therefore, equations (D.12)–(D.13) give

\[
\begin{align*}
\sigma_2 &= \frac{1}{2} \left[ \left( 1 + \frac{\sqrt{6}}{m} \right) \sigma_1 - \frac{3\pi}{4} \delta K \right], \\
\sigma_3 &= \frac{1}{2} \left[ \left( 1 + \frac{\sqrt{6}}{m} \right) \sigma_1 + \frac{3\pi}{4} \delta K \right], \\
\sigma_4 &= -\frac{3}{2} \sigma_1. 
\end{align*}
\]

Finally, substituting (D.16) into (40), we obtain

\[
\begin{align*}
\sigma_1 &= \pm \frac{2\Delta_{K\sigma}}{\sqrt{\left( 1 + \frac{8}{2^7} m \right)^2 + \frac{13}{2}}}, \\
\sigma_3 &= \frac{2\Delta_{K\sigma}}{\sqrt{\left( 1 + \frac{8}{2^7} m \right)^2 + \frac{13}{2}}}, \\
\sigma_4 &= -\frac{3}{2} \sigma_1. 
\end{align*}
\]

where \( \Delta_{K\sigma} := \epsilon^2 - \frac{9\pi^2}{32} (\delta K)^2 \). Here, we note that, in order for the time-optimal evolution to exist, i.e. for the \( \sigma_i \) to be real, we have a more precise condition that must be satisfied by the couplings in the Ising Hamiltonian, i.e. we must have that \( \Delta_{K\sigma} \geq 0 \) or, in terms of the fidelity, using equation (36):

\[
|\Delta K| \leq \frac{16}{3\pi} \sqrt{1 - f}. \tag{D.18}
\]

We can now proceed in determining the perturbative expansions in \( \delta K \) of the time-optimal solutions (D.6)–(D.9) for \( f_- = 3 \), which explicitly read (to the lowest order in \( \delta K \) and \( \sigma_1 \)):

\[
\begin{align*}
\tau_\ast &\simeq \pi \sqrt{\frac{3}{8} \left( 1 - \frac{\delta_{K\sigma}}{2} \right)}, \\
\dot{\Omega} &\simeq m \sqrt{\frac{8}{3} \left( 1 + \frac{\delta_{K\sigma}}{2} \right)}, \\
\omega_K \sin \phi &\simeq \left( 1 + \frac{\sqrt{8}}{3} \right) \left[ 1 + \frac{\left( \sqrt{2} + \sqrt{3} \right)}{\left( 2\sqrt{2} + \sqrt{3} \right)} \delta_{K\sigma} \right].
\end{align*}
\]

where we have defined

\[
\delta_{K\sigma} := \delta K - \frac{2f_-^\sigma}{3\pi}. \tag{D.22}
\]

Finally, the value of the integer \( m \) is also fixed by minimizing \( \tau_\ast \) in (D.19), i.e. by minimizing

\[
f_-^\sigma := -\frac{1}{2} \left( 1 + \frac{2\sqrt{6}}{m} \right) \sigma_1 \tag{D.23}
\]

with \( \sigma_1 \) given by (D.17), with respect to \( m \) (and the sign of \( \sigma_1 \) in (D.17)). The result is \( m = 1 \) and sign(\( \sigma_1 \)) = +, for which \( f_-^\sigma = -\left( 1 + 2\sqrt{6} \right)[\Delta_{K\sigma}/(27 + 4\sqrt{6})]^{1/2} \). This gives the final formulae (41)–(43) of section 5.

A similar computation can be performed for the case of the target CNOT(1, 3), equation (51), and for the ‘rotated’ Hamiltonian (49), discussed in section 6. In particular, one has to choose \( n_2 = n_1 + 2q, n_3 = n_1 + 2s, n_4 = n_1 + 2r + 1 \), with \( n_1, n_2, n_3 \) and \( n_4 \) being the positive integers, and \( q, s \) and \( r \) integers. One obtains, for \( n_1 = 2 \) and \( n_2 = n_3 = n_4 = 1 \), the same time-optimal solutions (41)–(48), except for a change everywhere in the sign in front of odd powers of the integer \( m \), due to the fact that now \( m = -1 \) is the value minimizing \( \tau_\ast \).
